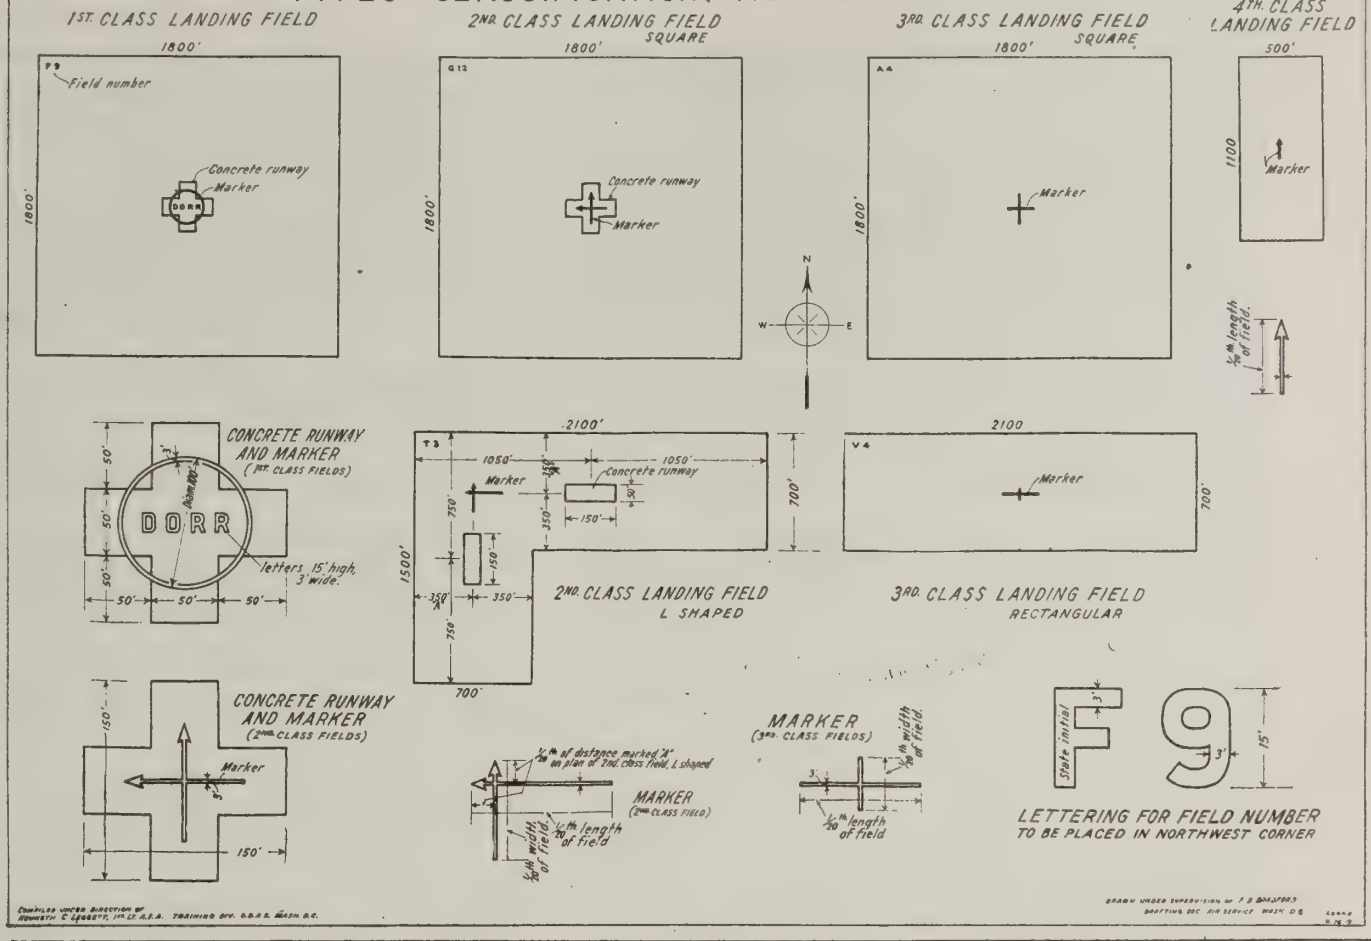
(d) Provision for informing pilots of available accommodations.

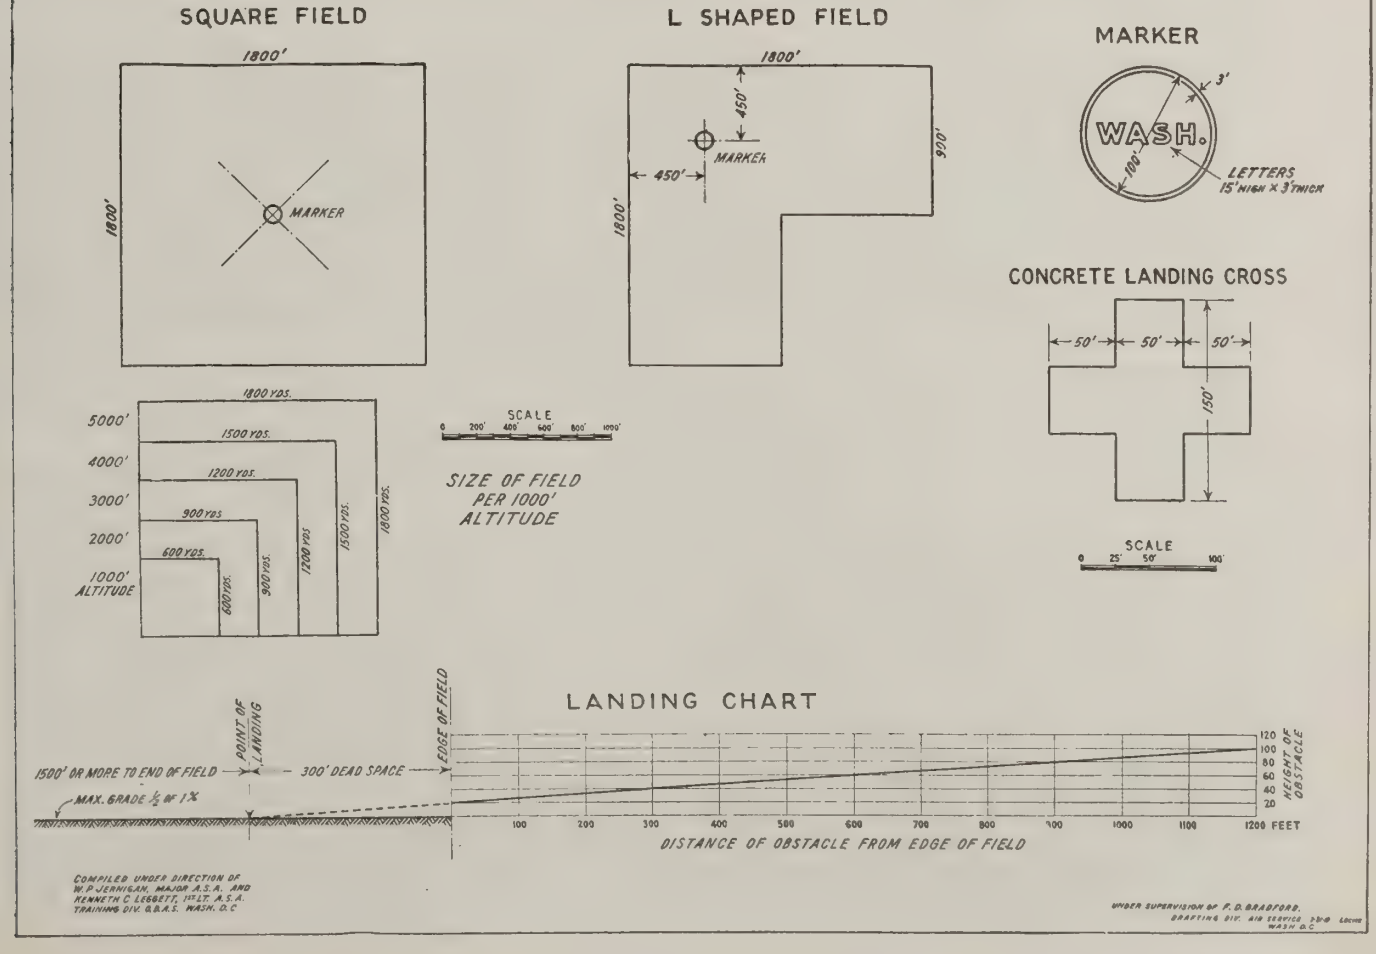


Fourth Class Landing Field.

1. Capable of landing only in emergency. Marked with single arrow indicating best approach and longest runway. Arrow 3 feet wide and length based on proportion 1 to 20 to 90 feet for 600 yards runway, supplies available or not available upon request.

It will be noted that the Atlantic City Airport is larger and better in every way than is required by government specifications for first class flying field.

LANDING FIELDS



TYPES CLASSIFICATION, METHOD OF MARKING

Compiled under direction of Kenneth C. Leggett, 1st Lt. A.S.A. Training Div. G.B.A.S. Wash. D.C.

Drawn under supervision of F. D. Bradford, Drafting Sec. Air Service Wash. D.C.

SPECIFICATIONS FOR LANDING FIELDS

Compiled under direction of W. P. Jernigan, Major A.S.A. and Kenneth C. Leggett, 1st Lt. A.S.A. Training Div. G.B.A.S. Wash. D.C.

Under supervision of F. D. Bradford, Drafting Div. Air Service Wash. D.C.

The AIRCRAFT TRADE REVIEW

Truck Repair Parts Delivered by Aeroplane

Wabash, Ind., May 10.—The first deliveries of repair parts for Service trucks were made on May 10 when two aeroplanes, operated by the Service Motor Truck Company, made a flight to Akron, Ohio. Repair parts were ordered by wire this morning by the Firestone Tire and Rubber Company for the Service trucks operated by them.

The wire was 12 minutes in transit, and 18 minutes after it was received at the Service Motor Truck Company the first plane was on its way, and the part ordered was delivered in Akron 2 hours and 45 minutes later. The distance covered was approximately 250 miles.

The Service Motor Truck Company is the first company in the United States to make use of aviation in a commercial way. They operate four Canadian JN-4 planes, which are under the control of experienced army fliers, who, in addition to delivering Service truck parts, have organized the Service Aviation, Training and Transport Company, which is training aviators, arranging for passenger flights, making express deliveries and staging exhibitions.

New Cantilever Models Being Constructed

So many demands are being made for two-seater "Bullets" that the Cantilever Aero Company of New York, has entered upon the manufacture of two new models. One will be a two-seater monoplane, the other a two-seater biplane.

Two of each of these models will be entered in the Pan-American Aeronautical Competitions at Atlantic City. Owing to the flexible wing construction and the entire absence of struts and wires, these aeroplanes are considered favorites in every event. Many college flyers are to be in this meet and are inquiring for Cantilever aeroplane knowing their great speed.

Dr. Christmas, president of the company and inventor of the flexible wing aeroplane said:

"The crucial test between the flexible wing aeroplane and the rigid wing aeroplane will come in the competitions at Atlantic City. Many of the rigid wing aeroplanes will use 300 or 400 horsepower engines with unusually large lifting surfaces and every accessory that can be put on an aeroplane to increase speed and lift, but with a small 165 horsepower engine, I look for the Cantilever Aeroplanes to break all records. Our Bullet has already made 197 miles an hour at ¾ horsepower and its good flying qualities are widely recognized.

"The new aeroplanes which we are planning will have retractable chassis—under the first retractable chassis patent ever issued in the United States. Thus with no struts, no wires, nor landing gear to affect the speed, and with a carefully designed engine and propeller, the Christmas Bullet can be expected to pass 200 miles an hour wtihout efforts and to be entirely independent of wind conditions."

American Glue 1918 Surplus Equal to $31.44 a Share

Net earnings for the American Glue Company for the year ended December 31, 1918, were $506,127, which compares with $1,893,634 for the year before.

Common dividends distributed aggregated $200,000, preferred dividends totalled $160,000, leaving a $114,317 surplus.

The Car of the C-5 is a product of the Burgess factory; the Motors were built by the Union Gas Engine Co.

Personal Pars

Victor N. Barton has resigned as mechanical engineer, Bureau of Aircraft Production, to accept the position of sales engineer with the Duplex Engine Governor Co., Brooklyn, N. Y. He will represent the company in Pennsylvania and the Southern States.

Joseph Berge, who was formerly manager of the aircraft division of the Champion Ignition Co., Flint, Mich., has been appointed chief engineer of the company.

George T. Briggs has joined the staff of the Sinclair Refining Co., Chicago, Ill., and will have charge of the sale of oil for lubricating internal-combustion engines. For the past 11 years he has been sales manager of the Wheeler-Schebler Carbureter Co., Indianapolis, Ind.

B. J. Cline has resigned as general superintendent of the aeronautic division, Nordyke & Marmon Co., Indianapolis, Ind., and vice-president and director of manufacturing in the Supreme Motors Corporation, Cleveland, Ohio, to accept the position of factory manager for the Templar Motors Corporation, Cleveland.

R. E. Clingan has resigned as Western branch sales manager of the Hess-Bright Mfg. Co., with offices at Cleveland, Ohio, and has been appointed sales manager of the Bock Bearing Co., Toledo, Ohio.

Eric S. Locke has resigned as drafting-room foreman of the Hall-Scott Motor Car Co., Berkeley, Cal. He has made no plans for the immediate future.

E. J. Hall has been discharged from the service of the Bureau of Aircraft Production with the rank of lieutenant-colonel, and has resumed his duties as vice-president of the Hall-Scott Motor Car Co., Berkeley, Cal.

Dr. Charles E. Lucke, who during the war was director of the Navy Gas Engine School at Columbia University, New York City, has been released from Government service and resumed his duties as head of the department of mechanical engineering in the university.

James W. Macpherson, who was formerly connected with the inspection section, Signal Corps, and the Bureau of Aircraft Production, as an inspector of aeroplanes and aeroplane engines, has resumed his engineering studies at Cornell University.

J. F. Richman, former superintendent and factory manager of the Cole Motor Car Co., Indianapolis, is now manufacturing manager of the Allen Motor Car Co., Fostoria, Ohio.

E. O. Sutton, treasurer of the Knox Motors Co., has been elected treasurer of the Militor Motors Co., New York City, which was recently formed by the merging of the Knox Company with the Militor Corporation.

Hon. Albert S. Burleson, Postmaster General
Hon. Otto Praeger, Second Assistant Postmaster General
J. B. Corridon, Superintendent, Division of Aerial Mail Service
Louis T. Bussler, Chief of Maintenance and Equipment

J. Clark Edgerton, Chief of Flying Operations
George L. Conner, Chief Clerk, Division of Aerial Mail Service
Eugene J. Scanlon, Chief of Supplies
Charles N. Kight, Special Representative

Celebrating Inauguration of Aerial Mail

The two aeroplanes that took to the air on May 15, one leaving Washington and one leaving New York, are the same that carried the mail a year ago and have been constantly in the service, and they are propelled by the same motors. One of these has been in the air 164 hours, flying 10,716 miles, and has carried 572,826 letters. It has cost, in service, per hour $65.80. Repairs have cost $480. The other plane has been in the air 222 hours, flying 15,018 miles, and has carried 485,120 letters. It has cost, in service, per hour $48.34. Repairs to this machine have cost $1,874.76.

The record of the entire service between New York and Washington shows 92 per cent of performance during the entire year, representing 128,037 miles travelled and 7,720,840 letters carried. The revenues from aeroplane mail stamps amounted to $159,700, and the cost of service $137,900.06.

The operation of the aeroplane mail service every day in the year except Sunday, encountering all sorts of weather conditions and meeting them successfully, has demonstrated the practicability of employing the aeroplane for commercial service. The service has been maintained throughout the year with a record of 92 per cent, gales of exceptional violence and heavy snow storms being encountered and overcome. Out of 1261 possible trips, 1206 were undertaken, and only 55 were defaulted on account of weather conditions. During rain, fog, snow, gales and electrical storms, 435 trips were made. Out of a possible 138,092 miles, 128,037 miles were flown. Only 51 forced landings were made on account of weather and 37 on account of motor trouble.

One of the lessons learned from the operation of the air mail service during the year is that the element of danger that exists in the training of aviators in military and exhibition flying is almost entirely absent from commercial flying. Second Assistant Postmaster General Praeger, in reporting to the Postmaster General the operations for the year, says that the record of the air mail service, which includes flying at altitudes of as low as 50 feet during periods of marked invisibility, throws an interesting light on this question.

Chicago-Cleveland Air Mail Service Started

Chicago, May 15.—The Chicago-Cleveland aerial mail service was inaugurated on May 15 by successful flights in both directions.

The first 'plane left here at 9.35 o'clock, piloted by Trent C. Fry. It was a machine of the De Haviland 4 type, carrying a mail bag weighing 450 pounds. It arrived in Cleveland at 12.48 p. m., making the trip from Chicago in three hours and thirteen minutes, including a five-minute stop at Bryan, Ohio.

The 'plane which left Cleveland at 10.30 o'clock, piloted by Edward Gardner, took the air at Woodland Hills Park and followed the New York Central tracks to the West, reaching Bryan, Ohio, at 11.15 and South Bend at 12.40 o'clock. It arrived in Chicago at 1.25 p. m. The trip consumed three hours and fifty minutes.

PERFORMANCE OF AVIATORS FOR THE YEAR, MAY 15, 1918—MAY 15, 1919

Recent Naval Orders

Lieutenant (junior grade) Charles B. Dushane, to duty naval air station, Pensacola, Fla.

Lieutenant (junior grade) M. E. Jensen, to duty commanding officer U. S. N. Aviation Repair Base, Queenstown, Ireland, in connection nucleus crews.

Lieutenant Henry U. Linkins, to duty Naval Air Station, San Diego.

Lieutenant Augustus M. Baldwin, to duty air station, Miami, Florida.

457 Loops with Passenger New World's Record

Washington, May 19.—According to a statement issued by the Department of Military Aeronautics a new world's looping record was established at Carlstrom Field by Lieutenant Ralph J. Johnson, who has many unrecorded stunts to his credit. He was accompanied by Second Lieutenant Mark R. Woodward as a passenger. Johnson made 457 continuous loops in his Lapere Fighter in one hour fifty-four minutes and ten seconds. His elevation varied from 6,000 to 4,000 feet.

Flying Fields to be Retained

Fifteen flying fields and five balloon schools are to be held by the Air Service as permanent training fields.

FLYING FIELDS

"Government Owned"

Rockwell Field, San Diego, Cal.; Langley Field, Hampton, Va.; Post Field, Fort Sill, Okla.; Kelly Field, No. 1, San Antonio, Texas.

"Leased—to be purchased"

March Field, Riverside, Cal.; Mather Field, Sacramento, Cal.; Carlstrom Field, Arcadia, Fla.; Door Field, Arcadia, Fla.; Ellington Field, Houston, Texas; Park Field, Millington, Tenn.; Souther Field, Americus, Ga.; Selfridge Field, Mt. Clemens, Mich.; Scott Field, Belleville, Ill.; Chanute Field, Rantoul, Ill.; Kelly Field, No. 2, San Antonio, Texas.

Balloon Schools

"Government Owned"

Balloon School, Lee Hall, Va.; Balloon School, Ft. Crook, Nebr.

"Leased—to be purchased"

Balloon School, Arcadia, Cal.; Balloon School, San Antonio, Tex.; Balloon School, Ft. Omaha, Nebr.

U. S. Navy Will Release All Temporary Officers

Washington, May 13.—All temporary officers who entered the navy for the war period only will be released within the next few weeks, Acting Secretary Roosevelt announced today. There are more than 1,000 officers in this status and they will be replaced by reserve officers who are accepting temporary commissions with the agreement to remain in the service until six months after peace is declared.

Figures for Manufacture of Service and Training Planes for Allies Given Out

(Prepared by Statistics Branch, General Staff, War Department)

Data for the plane production of France, Great Britain, and Italy for the period January 1 to October 1, 1918, show that service planes constitute 79 per cent and training planes 21 per cent of the total.

The following table shows the production and percentage distribution for each of the principal Allied countries:

Country	Service Planes	Training Planes	Total	Per Cent Service	Per Cent Training
Italy	2,507	421	2,928	86	14
France	15,326	3,507	18,833	81	19
Great Britain	17,854	5,655	23,509	76	24
Total	35,687	9,583	45,270	79	21

Army Issues Call For Flight Surgeons

Washington, D. C.—The Air Service now requires that a flight surgeon be detailed at each of its 15 active fields.

Owing to the discharge of a large number of temporary medical officers, the Air Service needs a number of medical officers of the permanent establishment as flight surgeons. Medical officers below the grade of lieutenant-colonel, who desire duty of this character, should communicate with the Chief Surgeon, Air Service, Washington, D. C., who will fill vacancies from among those who volunteer. Authority has been granted medical officers to become pilots if they pass the necessary physical qualifications and as such receive the 25 per cent. flying pay.

Air Service Demobilization

The net decrease in the total commissioned and enlisted strength from the date of the armistice to April 17 was 69 per cent.

The following table shows the present distribution of personnel as compared with November 11, and per cent of net decrease. The April 17 figures do not include 514 men at demobilization camps awaiting discharge.

	Nov. 11	Apr. 17	Per cent net decrease
Cadets	5,775	824	86
Officers	20,586	6,220	70
Enlisted men	164,266	51,384	69
Total	190,627	58,428	69

69 Per Cent of Present Air Service Personnel Overseas

During the week ended April 17, 1919, the Air Service personnel overseas decreased 424 men as against a weekly average of 2,268 during the nine preceding weeks. The strength of the Air Service in the United States and overseas is shown for various dates in the following diagram:

	U. S.	Overseas
Nov. 11	111,846	78,786
Dec. 2	115,216	78,061
Dec. 26	99,010	59,917
Jan. 30	46,919	57,527
Feb. 27	33,649	53,087
Mar. 28	25,347	41,800
Apr. 10	20,636	40,855
Apr. 17	17,753	40,431

THE PROBLEMS WHICH CONFRONT THE AIR SERVICE

IN an address delivered before the Southern Aeronautical Congress at Macon, Ga., Major General Charles T. Menoher, Director of Air Service, spoke as follows:

In order to give an idea as to the problems which confront the Air Service, and the aims and objects in view, I will quote extracts from various public utterances made in the last two months by the present Director of Air Service.

"Now that peace has come and the various activities disturbed by war are returning to normal channels, we may look for a steady flow of conservative development. We, I believe, would like to see the United States, where aviation had its birth, gain and maintain the lead in aviation. To do this will require the co-operation and co-ordination of all our activities and resources.

"Because of the lead given the Air Service of the War Department by the enforced effort due to the war, civilian activities," and in this is included all activities outside of the governmental departments, "are sure to look to the Air Service for assistance for some time to come. This places upon the Air Service an obligation of assistance and co-operation in carrying on the work. This, I believe, is a fortunate circumstance for the Air Service, provided it fulfills its obligation.

"It will be the endeavor of the Air Service to fulfill these obligations as far as possible, subject to the limitations of Congressional appropriation. The acceptance of such co-operation and assistance by civilian activities should carry with it a reciprocal obligation, and appeal is hereby made for such reciprocal obligation.

"It will be in the matter of research and development of material that we must look in the future to civilian activities, unless Congress should appropriate for this purpose more liberally than we have now reason to hope for. The Air Service must render every encouragement possible to private manufacturers to develop new and improved types and at the same time carry on its own work along these lines as far as possible. * * * Within the Air Service itself there must be an active, progressive policy. From its present position of advantage, it should be able to lead the way in most phases of air activities. It should never be content to simply maintain its existence."

Again, "Of the many problems pressing for solution in the general field of aeronautics, the most urgent is that of proper and adequate rules and regulations for the navigation of the air. First and foremost among these rules should be those covering matters of qualifications

(*Continued on page* 554)

FOREIGN NEWS

British Firm Adds $10,000 to Trans-Atlantic Prize

In order to encourage the trans-Atlantic flight, the Ardath Tobacco Company of England have added 2,000 guineas to the prize offered under the Royal Aero Club rules.

French Government Issues First Civilian License

Mdlle. Jane Herveu, who was one of the first ladies to secure a pilot's certificate, has received permission to resume flying—the first civilian, it is said, to be so honored in France since the armistice. She is at present practicing on a Caudron at Issy-les-Moulineaux.

Civilian Aviation Ban Lifted in England

London.—The Air Ministry lifted the ban on civilian flying on May 1. It was also decided to give permission for flying between the dates of April 17th and 22d, inclusive. The flights must be made from an approved aerodrome, subject to an undertaking being given that the rules of the aerodrome will be strictly observed, and will be limited to a radius of three miles from the aerodrome. Service-type machines, which have been built under the supervision of the Aircraft Inspection Department, may alone be used.

During the four days' civilian flying Handley Page pilots at Cricklewood carried 800 passengers without accident; the youngest was aged 6, the oldest 81. At Hamble, Southampton, 400 passengers were carried in Avro machines.

Afghan Rioters Quieted by Aerial Bombardment

London.—According to news dispatches dated May 12, the British have driven the Afghans from Ashrasiakhel and aeroplanes crossed the frontier and bombed the enemy position at Loidatta with good results.

Bristol Plane for Film Delivery

One successful use of the aeroplane for commercial purposes is that of the Bristol fighter, piloted by Capt. A. M. West, R.A.F., which is engaged on delivering Harma films to various provincial towns including Manchester, Lincoln, Newcastle, Leeds, Birmingham and Glasgow. It is also being used to distribute leaflets advertising the films. The usual load is 6,000 feet of film and 30,000 leaflets.

Cortinez Recrosses Andes

The Chilean pilot, Lieut. Cortinez, who crossed the Andes in a Bristol aeroplane recently from Santiago and landed at Mendoza (Argentina), has recrossed the range on his return to Santiago, the journey occupying two hours. Lieut. Cortinez reached a height of over 20,000 feet.

Seven Airways and 120 Aerodromes for Civilian Aviation in England

London, May 14.—The commercial air stage has been officially ushered in by Great Britain.

Civilians are traveling on seven great airways, radiating from London to all parts of the United Kingdom and to points outside. One hundred and twenty aerodromes and landing stations have been placed at the disposal of commercial air traffic, thirty-four main aerodromes being opened at once.

Marine Corps Aviators Use Tear Gas Bombs on Haitian Bandits

In order to cause bandits of Haiti and Santo Domingo to surrender without the employment of large numbers of troops and unnecessary bloodshed, Marine Corps aviators have been directed to undertake a month's tear gas dropping campaign. It is anticipated that this "genteel terrorism" will so affect the natives by appealing to their superstitions and cause them to surrender without further fighting.

Permanent International Aircraft Standards Commission Being Formed

London.—The necessity for the creation of an international body, with direct government co-operation and official recognition, for the study of industrial aeronautics, and the setting up of international standards best suited to the effective and rapid construction of aircraft, was urged by the American delegates at a series of International meetings held in London in March, 1918, the opening meetings of which were addressed by Mr. Winston Churchill.

As a result, the International Aircraft Standards Commission was appointed at an international conference held in London in October last. The conference was composed of the following delegates: *British:* Sir Arthur Duckham, K.C.B. (chairman); Mr. C. V. Allen (secretary of British Aircraft Constructors); Brig.-Gen. R. K. Bagnall-Wild, C.M.G., (Aeronautical Inspection Department); Lt.-Col. C. F. Jenkins, M.B.E. (Technical Dept. Air Ministry); Captain Neal (representing the Inter-Allied Advisory Committee sitting in Paris); Col. H. W. Outram (Aeronautical Inspection Department); Col. A. Reiss (Supply Department, Air Ministry). *American:* Dr. W. F. Durand. *Canadian:* Capt. R. J. Durley, Mr. G. M. Waterman. *French:* Comm. C. Grard, Comm. C. Martinot-Lagarde, Lt. A. M. Portevin, Lt. C. Frechet. *Italian:* Capt. Bonomi, Capt. E. Ferrua, Capt. A. Rota.

The British, Canadian, French and Italian delegates were able oe report to the meeting that national committees were in process of formation in their respective countries. As regards America, owing to the fact that the Department of Aircraft Production was in a state of reorganization, no committee had been nominated.

At the October conference eleven international advisory committees were formed to study questions which appeared susceptible to internationaal agreement. Arrangements are now being made to hold in Paris in April or May next meetings of these committees, which are as follows: 1. Mechanical Tests. 2. Chemical Analysis. 3. Tolerances on Bars. 4. Magnetos. 5. Sparking Plugs. 6. Propeller Hubs. 7. Ball Bearings. 8. Axles, Hubs, Rims, Tires. 9. Electrical. 10. Steel Tubes. 11. Tests on Wood.

The British, Canadian, and French committees have nominated their representatives to attend these meetings and preliminary details are now being arranged. It would be most unfortunate if these meetings were to be held without American representation, seeing the keen interest taken by the American delegates at each conference they attended.

The objects of the commission are briefly: (1) To study and recommend industrial and technical standards best suited to the effective and rapid construction of aircraft with the maximum standardization of material specification and interchangeability of component parts and the minimum of maintenance cost; (2) to keep abreast of all inventions and progress by constant and periodic revision of the standards recommended; (3) to secure approval and government acceptance of the "International Aircraft Standards" issued by the commission.

It will be seen, therefore, that the commission has been entrusted with a task of the greatest importance, a fact which is fully realized by the Allies, for besides the countries cited above as co-operating in the work, the Japanese Government have agreed to form a committee and there is likelihood of Belgian representation shortly.

Amsterdam Aeronautical Exposition Under Auspices of Dutch Officials

Amsterdam, Holland.—During the months of July and August there will be held at Amsterdam, Holland, an international Aeronautical Exposition, under the auspices of the Chambers of Commerce of Amsterdam and Rotterdam, as well as the Secretaries of the Interior, War, Agriculture and Commerce, and of Water Works, the Governor of the Province of North Holland and the chairman of the Royal Dutch Association for Aircraft. The honorary members are some of the most prominent men in Holland in commerce, shipping and banking, and the executive committee is largely composed of members of the Royal Dutch Flying Corps. With such support the success of the exposition is practically assured. It is confidently expected that the foreign aeroplane industries will generally participate and many requests for space have already been received from moreign countries.

In addition to a large number of aeroplane exhibits, parts, materials and instruments will be displayed. Aircraft for purely military purposes will be excluded from the exhibit.

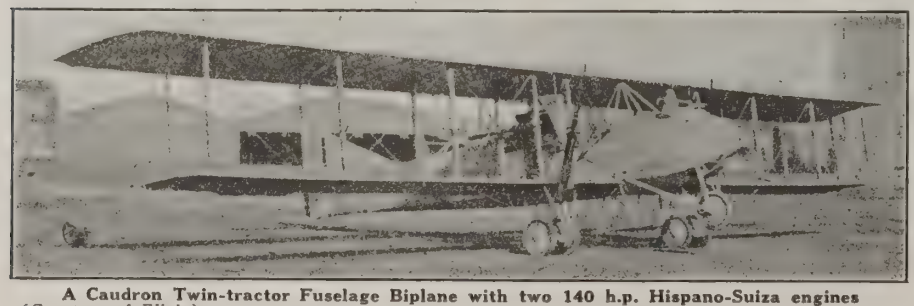
Brigadier-General Duval New French Air Chief

According to a decree of April 15th, Colonel Dhé has been replaced in the office of Directeur de l'Aeronautique Militaire by Brigadier-General Duval.

Colonel Dhé has held this office since November, 1917, and is responsible, in a large measure, for the successful unification of the French naval and military air services. He was in charge of the organization of a Department of Civil Aeronautics but owing to lack of co-operation Colonel Dhé resigned. He will devote his great capacity and experience immediately in civilian work now being organized.

Breguet, Bleriot and Caudron in Huge Aero Transport Combine

Paris.—A French corporation has recently registered under the name of the Compagnie des Messageries Aériennes, with large capitalization for the promotion of all forms of aviation in France, French colonies and abroad. Routes will be established for the carrying of mail, packages, merchandise and passengers.



The offices of the concern are Avenue Kléber, Paris, and its first administrators are Messrs. Louis Bréguet, Louis Blériot, Réné Caudron and the Morane-Saulnier Company.

France Doubts German Commercial Aero Plans Have No War Aim

Paris, May 10—"The air should have become the property of the League of Nations," says Le Matin, in calling attention to the fact that in the peace treaty handed to the Germans no reference was made to the building and equipment of aeroplanes by Germany for civilian purposes.

"What difference is there between military and bombarding aviation and civilian flying? Civilian aviation lends itself to all sort of camouflage. A peaceful postal aeroplane or a passenger machine can easily and rapidly be crammed with explosives and armed with machine guns. In a few minutes aero stations can be transformed in huge aerial mobilization centres."

Then after pointing out the greatest danger from such transformation of aerial services for France, Le Matin puts forward the following proposition: "The League of Nations, by taking over the air police, by creating an Interallied organism for the exploitation of the air and only allowing Germany to participate in the exploitation under its control, could save the civilized world from the most redoubtable of its dangers."

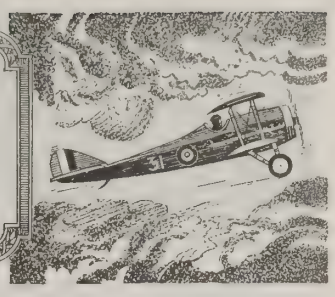
Aerial Progress Forced Canadian Pacific to Enter Aero Transport Field



"When we consider that we are approaching a new epoch in air transportation, the Canadian Pacific Railroad's application for an air charter is only natural," is the way Grant Hall, vice-president of the road, explained it. "Progress in aviation is so rapid that it is incumbent on the C. P. R. to prepare to enter the field."

Mr. Hall pointed out that the Western prairies of Canada, with their absolute lack of fog and mist—the airman's worst enemy—offered an ideal field for profitable aerial transportation. The success of the service between Berlin and Frankfurt during two years of war and the fact that Canada is supplied with an abundance of war aviators who can be used as pilots were factors, Mr. Hall said, that insured the success of such a venture.

Prizes for Model Aeroplane Contest

AERIAL AGE has decided to award two sets of medals and a beautiful cup for the coming contests, to be decided during the month of June.

These medals of gold, silver and bronze are to be awarded to the first, second and third in each racing model aeroplane event.

The cup is very neat, and the winner of the scale model construction contest will have something he will be proud of for years to come, as he will not alone possess an enviable prize, but he will be the owner of the finest model in the United States. This is an absolute fact, because some of the most expert model builders have signified their intention of competing in this event.

It makes no difference which contest is held first; the only thing necessary is to have at least five competitors in each event of the flying contests and these five competitors need not live in the same town or city, but they must compete during the same meeting.

The construction contest will be decided by the builders of such models sending in clear photographs, together with a good description of the model and how it was constructed. The best of these photos and descriptions will be used later in AERIAL AGE for the benefit of the readers.

To conduct the flying contests, it is necessary to have the flights witnessed by some influential citizens in your city or town, and if you have a branch of the Aero Club of America in your city, invite a few of the members to judge and witness the flights.

The Illinois Model Aeroplane Club and the Aero Science Club of Chicago and New York respectively will no doubt have teams in the contests, and I look for some competition between these rival clubs.

The Illinois has had the better of the New York contingent for the past couple of years, but from what Mr. S. Y. Beach of the latter club told me a few days ago, the Illinois club will have to travel some if they win any of the above prizes.

I should not be surprised to see some dark horse come through and beat the members of both of these big clubs, as I have received many photos and reports of wonderful models and their long flights from out-of-the-way places. These are the people we will no doubt hear from. The Texas boys have gained considerable knowledge since the Aviation Section opened up new fields there during the war, as have the California and Florida boys.

Readers as far off as the Hawaiian Islands are entered, so the winners will be real champions in their respective events.

The prize winners will be invited to send their photographs, holding the winning model, to the Model Editor of AERIAL AGE for publication, after which the prizes will be awarded.

We hope to have another such contest for water machines later in the summer, and owing to the difficulty of successfully launching a model from the water, these contests should be as well contested as the hand launched and R.O.G. events.

To conduct a contest successfully proceed as follows:

Have a judge for the measuring of the distance or for taking the time of flight. (If a distance contest, the distance that the models lands from the starting point is measured in a straight line, regardless of the circles the model might make.

This distance is measured with a steel tape or a cyclometer working on an accurately measured disk or wheel. This cyclometer is mounted on a forked handle, to which is fastened a wheel two feet in circumference. Two pegs directly opposite each other are fastened to the wheel in a position to strike the cyclometer and register each revolution Each revolution registers twice, thereby showing a distance of two feet.

Jennings Machine Works Announces New Catalog

The Jennings Machine Works, Uniontown, Pa., announce a new catalog for Ford Motored Aeroplane Fittings, also a full line of parts for light plane construction. They also do general machine work in the way of engine rebuilding and manufacturing of engine parts.

The fittings turned out by the above company have been examined and tested by the writer and have proven entirely satisfactory inasmuch as they follow out the designs suggested in the Ford Motored Aeroplane articles which appeared in AERIAL AGE recently. It would be worth while for any one contemplating building a Ford Motored Aeroplane or other light machine to write this company for their new price list.

The model shown in the accompanying photograph was designed and constructed by Mr. Wallace A. Lauder of Summit, N. J. This model flew a distance of 3,537 feet, when launched from hand, making a new world's record, in 1916. With the chassis attached the model has made flights of over 100 seconds each. This is the type of model that will be used in the coming contest

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

David McK. Peterson
(Major A. S. (M. A.) D. S. O.
Killed in Aeroplane, Daytona, Florida
March 16, 1919

So much a warrior, relatived to wings
He climbed the blue-shot, blood-swept steeps of war
To battle for the requiem of kings—
So much a Thor!

So much a man, he bore in dignity
His honors; masked their colors rather than
Displayed, and courted anonymity—
So much a man!

So much a friend, so kindly and sincere,
So reverencing truth, so quick to bend
Regard to this of smile, to that of tear—
So much a friend!

So much a Son born in a deathless love,
So much apostle—oh, this earthly one—
God must have felt the need of him above—
So much a Son!

Sgt. Roy Harris Russ.

(David McK. Peterson, a Major in the Air Service and rated a Military Aviator, winner of the Distinguished Service Order, was killed in Daytona on March 16, 1919.)

"Do you hire aeroplanes here, sir?" asked the shy-looking man.

"Certainly. What do you want one for?"

"To look for a servant."

"But wouldn't you be better able to get one at a registry office?"

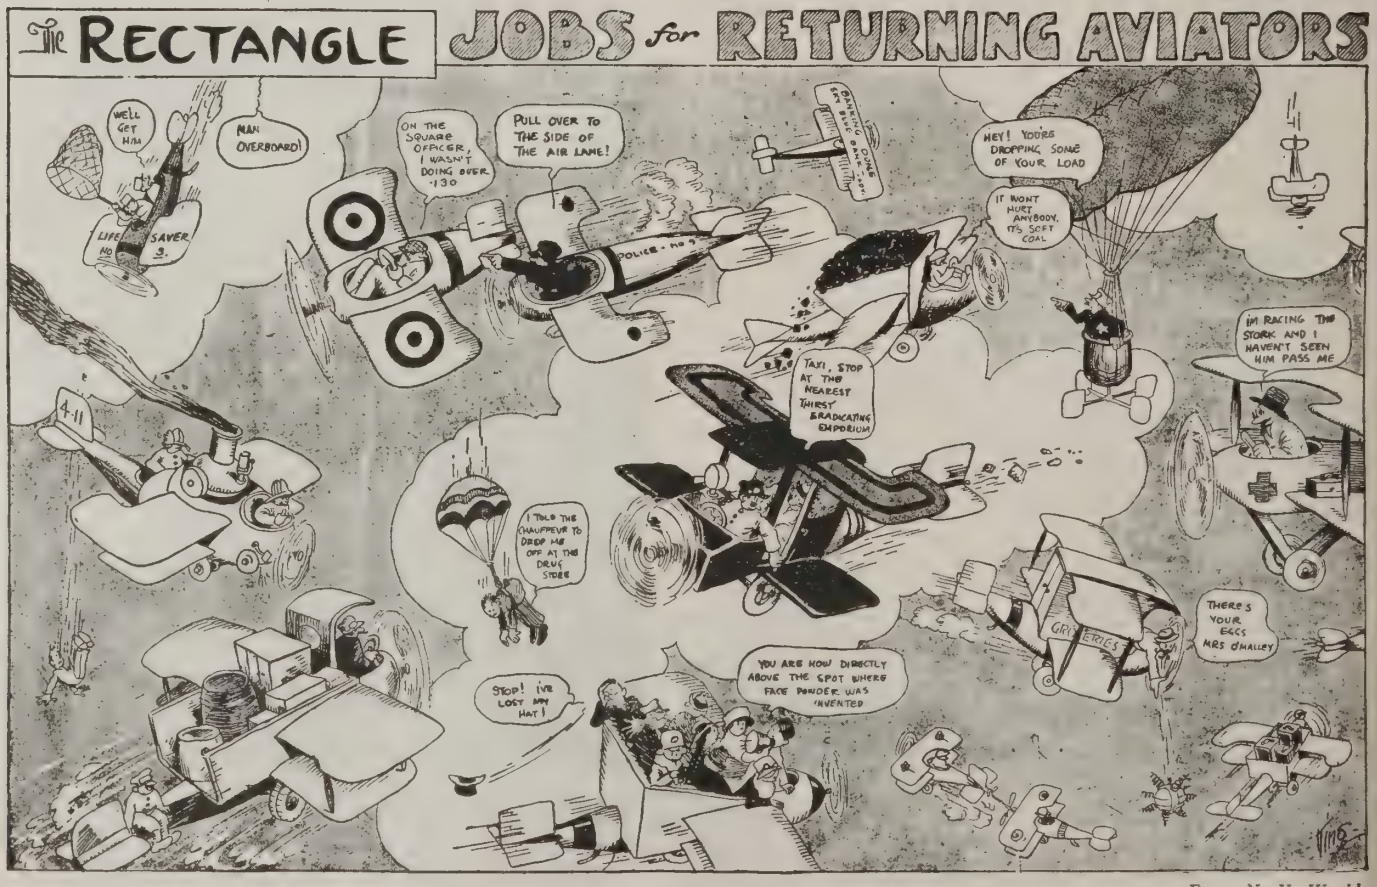
"No," replied the shy man; "not the one I want. I want to look for our own girl, who tried to light the kitchen fire with kerosene."—*From Aircraft.*

Mother Goose Revised

Little Jack Ladd, sat in a Spad,
To see how the derned thing worked.
He reached out his thumb and pulled back the gun
(10,000 dollars gone home to the folks.)

—

Hey diddle diddle, the prop and the fiddle
The Liberty flew over the moon
The 15 looped to see such sport
And the 23 ran away with the spoon.

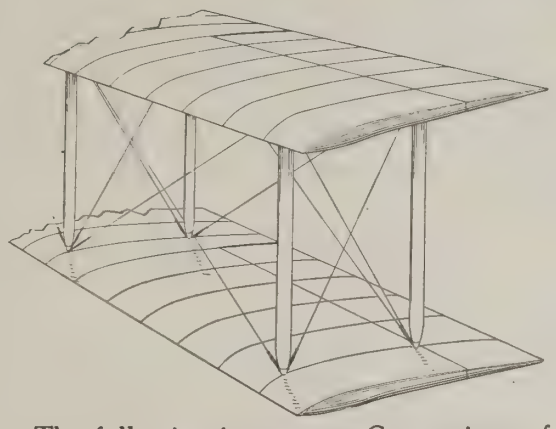


We Agree With You

"I hear you are going to fly the Atlantic, Jones?"

"That's so."

"But don't you think as a Britisher it would be better to start from this side?"



"Not on your life. Since they've adopted prohibition in the States the incentive to get away will be stronger."—*Aircraft.*

EVERY FIRST CLASS AEROPLANE REQUIRES A RETRACTABLE CHASSIS

COMPARISON OF RESISTANCE AND WEIGHT OF K-BAR AND DOUBLE LIFT TRUSS SYSTEMS

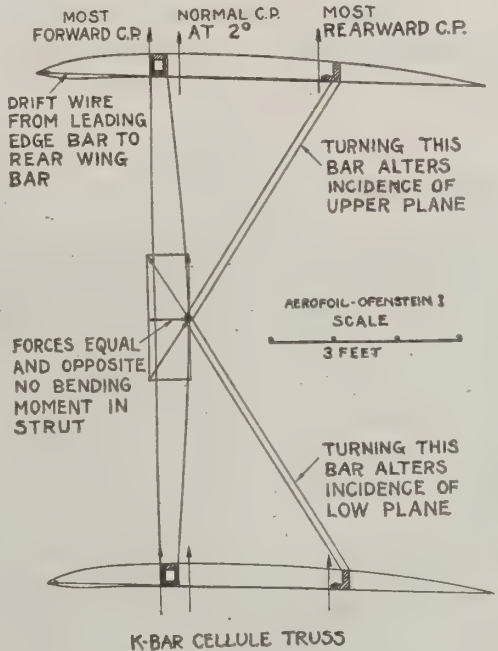
The following is an exact Comparison of Resistance and Weight:

The K-bar Truss reduces interference by eliminating interplane struts and wires and also by affording increased Gap cord ratio.

At a speed of 100 M.P.H.,
Wing loading of 9#/sq. ft.,
Safety factor of 8,
Aspect ratio of 6,
Gap/chord ratio of K-Bar Truss...1.143
Gap/chord ratio of Double Lift Truss...1.000

Resistance of K-Bar Truss is $\frac{97.2}{185.0}$ = 52.5% of resistance of Double Lift Truss.

Weight of K-Bar Truss is $\frac{106.45}{146.57}$ = 72.7% weight of Double Lift Truss.



Normal C. P. near central wing bar, only light forces at most rearward C. P.

meadows between the resort and the mainland towns, and record time for the ten-lap is expected to be established with eight colleges vieing for honors and a share in the cash prizes offered under the terms of the will of Mr. Samuel H. Valentine. This competition does not endanger the amateur status of the competitors.

The new entrants for the event, which is the second of the big series planned by the Pan-American Aeronautic Convention, are Lieut. D. Greeg and Ensign Marion Sulzberger, representing Harvard University; Lieut. G. A. Zabriskie and Ed. Townsend, of Dartmouth College; Ensign Alfred A. Beckwith, of Yale University, and Melvin W. Hodgdon, flying the colors of Tufts College. Lieut. Ferd Eble and Ensign Charles H. Payne will represent University of Pennsylvania; Lieut. G. W. Shaw, U. S. N., New England Conservatory of Music, and Lieut. Jack Frost, Columbia, and Augustus Post, of Amherst College, will make their second attempt for the "expense money."

The many scientific addresses and aerial transportation charts and tables exhibited at the Second Pan-American Aeronautic Convention and Exposition.

Testimonials to Trans-Atlantic Flyers

The news that the NC-4 had arrived safely in the Azores was lustily cheered by the delegates of the twenty-two nations attending the Second Pan-American Aeronautical Convention. The guests arose as a unit in tribute to the daring crew which accomplished the task, and burst out in enthusiastic cheers for Commander Read and his associates.

Colonel William A. Bishop, the Canadian ace who is officially credited with bringing down 72 German planes, was among the guests at the luncheon.

Commenting on the trip of NC-4, President Hawley said:

"The successful flight of the NC-4 to Horta, in the Azores, is indeed a marvelous achievement, and reflects the greatest possible credit upon the United States Navy and the intrepid navigators of the winged ship. It presages successes in the achievement of the dream of man, to bridge the Atlantic. Doubtless the NC-4 at least will finish the journey in one more leap to Lisbon.

"As President of the Aero Club, I extend my heartiest congraduations to the United States Navy and to the American people. It is an event which will live as long as history. It has demonstrated the value of the navy Liberty motor and has vindicated that highly valuable piece of mechanism, despite the early criticisms which were directed against it."

Henry Woodhouse, Vice-President of the Aerial League of America, and author of the textbooks of military and naval aeronautics, said:

"The crew of the transatlantic fliers are the pathfinders of a new age. Inventions, particularly inventions that have increased the speed of transportation and intercommunication, like the steamship, the railroad, the telegraph, and the telephone, have changed world conditions socially and commercially. The advent of the steamship made the Atlantic the central basin of the world, succeeding the Mediterranean. Yet all of these inventions in their early stages hardly held as much promise of usefulness as the aircraft does today."

Captain Robert A. Bartlett, the explorer, a delegate to the convention here, said:

"Now that the flight is an accomplished fact, it can be duplicated in the Arctic. Weather conditions there in June and July are better than these men had, there being daylight for twenty-four hours in the day. To the unbelieving Thomases, this transatlantic feat should convince them that the flying boat has come into its own just as the steamboat did. It is a glorious event, and I trust it will stimulate deeper interest in my polar flying trip."

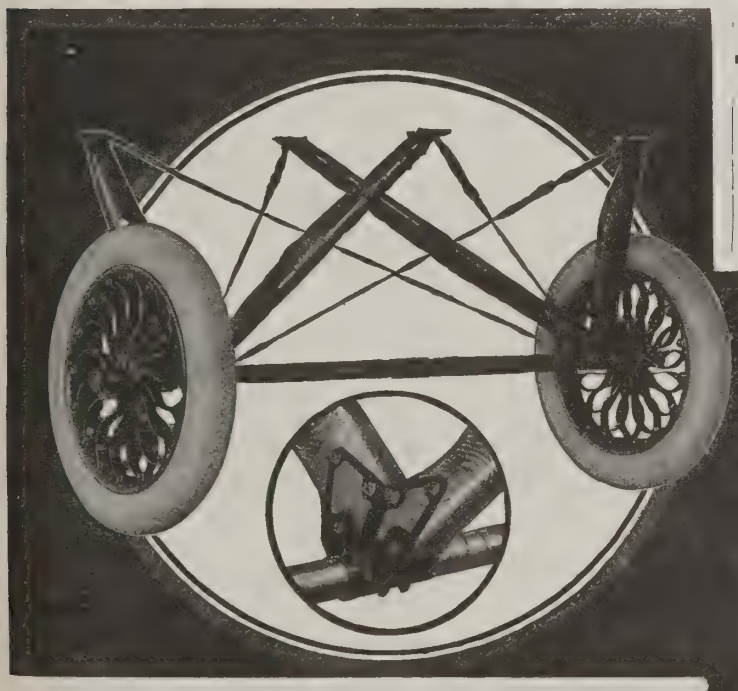
(*Continued from page* 533)

it has a capacity of 180,000 cubic feet. Cruising speed, 42 M.P.H.; climb, 1,000 feet per minute.

The car is of streamline form, 40 feet long, 5 feet in maximum diameter, with steel tube outriggers carrying an engine at either side. Overall width of outriggers, 15 feet. Complete weight of car, 4,000 pounds.

Seven passengers may be carried, but the usual crew consists of four. At the front, the coxswain is placed; his duty is to steer the machine from right to left. In the next compartment is the pilot, who operates the valves and controls the vertical movement of the ship, and aft of the pilot the mechanicians controlling the engines. At the rear cockpit is the wireless operator.

The engines were made by the Union Gas Engine Company and are 125 H.P. each.



Out of our War Production of 25,000 Paragon Propellers one third was furnished to the Royal Flying Corps. They were designed by us and made on honor by our own methods with no inspection until finished. We know our part of the business. Our customer had confidence in us. The results proved how well that confidence was justified —only four final rejections out of eight thousand propellers—more speed and faster climb than any other design.

NEW YORK OFFICES 299 MADISON AVENUE

New York, May 16, 1919.

Messrs. Average Man & Everyman
Anywhere, U. S. A.

Gentlemen:

In answer to your telepathically-received (mental) inquiry, "IS FLYING SAFE?" would say that according your inquiry immediate attention affords the writer much pleasure, in that he has been actively and successfully associated with European aeronautical enterprise and progress since 1912, and American since 1911.

During 1913 and 1914 the writer personally supervised passenger flights for virtually all of Shakespeare's "Seven Ages of Man" - and Woman. The latter embraced aerial trippers ranging from prattling baby girls of three years to dear old ladies of 75 and 82 years of age.

In 1914, under the pilotage of one or another of Hendon (London) aviators, the Countess of Rutland, the Countess of Dudley, Lady Victoria Perie, Miss Trehawke-Davis, and over a score of other prominent leaders of British society, paid as high as $2500 for the "privilege" of looping the loop in an airplane. Lord Carberry redeemed his ancestral estates from debt by carrying passengers and giving flying exhibitions throughout Great Britain.

More recently, the heir to the British throne flew over the battle lines in France, and yesterday, LOOPED THE LOOP IN AN AIRPLANE OVER THE HEART OF LONDON. We may assume that flying is fairly safe when the future hope of the British Empire indulges in aerial acrobatics. The Countess of Drogheda is presently giving flying exhibitions in aid of the British Red Cross. Premier Lloyd George frequently flew between London and Paris to attend the Peace Conference, as did Bonar Law, who owns an aero-limousine. King Albert of Belgium asserts it is safer "Up there" than "Down here". Other instances may be quoted.

In March of last year, Senator Harry S. New, Senator Gore, Congressman Schall (the blind Minnesotan representative) and other prominent men, executed every known form of aerial gymnastics over the capitol at Washington. And so on, ad infinitum.

You can now the better appreciate that flying IS safe,- provided, of course, you have a safe machine. Would you like to know why the BELLANCA TWO-SEATER is a SAFE MACHINE? And also why it "fits well around the pocket-book"?

Yours for safe flying,
MARYLAND PRESSED STEEL CO.,

(*Continued from page* 547)

and licensing of pilots. The rules should cover also such activties as general interstate flying, coast defense patrol, postal service, forest patrols, commercial photography, aerial transport service, sports and recreations, exploration, night flying, police service, smuggling and incendiarism.

"On account of numerous and urgent requests from various sources throughout the country for assistance in the matter of exhibits and flying exhibitions, it was found necessary to announce some policy in regard to participation by the Government in such activities, and the following policy in regard thereto was announced.

"The Air Service will give favorable consideration to any project of this sort which has for its object aerial performances without remuneration, for development, charitable or co-operative purposes of any international, national, state or civic character, but must adopt as a War Department policy disapproval of any project which involves competition of Air Service teams or individuals with private clubs or enterprises for money or other prizes or trophies" Again, "It is considered an improper use of the time of flyers and of Government property to compete for purses and individual prizes."

In line with the policy previously announced regarding encouragement to private manufacturers, it has been stated on numerous occasions by the present Director of the Air Service that we are desirous of doing everything that is possible and legitimate in the way of encouraging manufacturers who have built up numerous plants during the war to "carry on" in the future. This is a difficult question to deal with. Unless we can give adequate orders for new planes, these manufacturers will have to go out of business as aeroplane manufacturers." Again, "If we do not have adequate appropriation for new orders, no progress in the way of improvement in type is possible. It can readily be seen how closely these two ideas are linked up together and how necessary it is to have a continuing policy, and financial assistance to carry out such policy. It is not desired nor is it considered desirable that the Government itself should undertake the manufacture of planes or engines in quantity. This must be left to private manufacturers.

What it is aimed to do, however, in this line is to establish and maintain an adequate technical engineering establishment where all kinds of experiments may be carried on, where we can even build experimental engines or experimental planes and the facilities of which can be placed at the disposal of investors in carrying on their work. This technical engineering center is now practically an accomplished fact. Then we aim to have a complete engine production plant, to be held as a matter of insurance against future contingencies, such plant not to be used for production by the Government except in time of great emergency, but to be available for such emergency or to be available for use by private manufacturers under contract in case the Government desires to place orders for engines. Such a plant is already available, belongs to the Government, having been paid for during the war. Such a scheme would save to the Government amortization charges in the future on any such contract as that referred to. The cost of maintenance, while idle, of the plant in question would be only nominal, but as a matter of insurance is of far-reaching advantage. It is aimed to do the same thing in regard to a plant for manufactured planes.

The foregoing will indicate in a very general way some of the problems confronting the Air Service and its policy in regard to civilian and commercial activities. I may say incidentally that this Congress is the kind of activity with which we desire to have full and complete "liaison." We are now in close liaison with the Navy Department and the Post Office Department, and it is to one phase of our co-operation with the Post Office Department that I now desire to invite your attention.

One of the aims of the Air Service is to prepare and publish for the benefit of the public at large guide books, road maps etc., similar to publications of that kind for the guidance, etc, of automobilists. Considerable work along this line has already been done, as may be seen by an examination of charts on exhibition at the Air Service Exhibit. The ultimate aim is to have the entire country charted and road maps available for the use of pilots—the whole system to form a complete network linking up all the important centers in the United States. In considering this question the idea at once occurred that there was no better opportunity to make use of the aerial mail service than this, and steps were taken to get in touch with the Post Office Department through the 1st Assistant Postmaster General, Mr. Otto Praeger.

The logical way to extend this network of aerial routes seems to be to municipalities conventiently and properly located to take up the matter and assist in this great work; to designate and set apart adequate landing fields for the use of the Air Service in cross country work, the mail service in handling the mail; and for the use of itinerant pilots. Such a scheme if carried out will serve many

(*Continued from page* 554)

purposes. It will not only fulfill the purposes just named, but will place the cities concerned "on the map," so to speak, and will pave the way for local benefits resulting from the development of intercity transportation, express service, emergency service, local mapping, police protection, etc. These municipal landing fields will also serve another very important purpose of which I will speak later.

The idea in this matter is to call upon certain municipalities to set aside landing fields under conditions which have been prepared and are now ready for distribution; that when so designated the field will be examined by representatives of the Air Service, the field and vicinity photographed, and then the facilities, which will be necessary at each field, installed. It is not my purpose to go into the details of the matter, these will be left to one of my assistants to present to the Congress at the appropriate time.

On account of the magnitude of this work and the claims that the various cities are likely to put forward as to priority, it has been considered necessary not to include all cities throughout the country at which we ultimately desire to establish landing fields, but to undertake just now only a limited part of the work —to provide a skeleton, so to speak, of the network, then to fill in the details later.

The following list of towns has been selected as the ones where we want to establish these fields in the first instance. It will be recognized that some of these are relatively unimportant in size, and perhaps commercially, but they were selected, more on account of location than commercial importance. The Government also desires to confine itself at present to cities where the aerial mail service requires stations or where they are required for the cross-country use of the Air Service. It is not intended that such limitations should in any way restrict the establishment of other landing fields at cities and towns where conditions warrant such action. These cities are:

Boston, Massachusetts	Flatonia, Texas
New York City, N. Y.	El Paso, Texas
Richmond, Virginia	Texarkana, Texas
Columbus, N. Mex.	Columbus, Ohio
Oklahoma City, Okla.	Tuscon, Arizona
Kissimmee, Florida	Phoenix, Arizona
Uniontown, Penna.	Yuma, Arizona
Raleigh, N. C.	Bakersfield, Cal.
Columbia, S. C.	Fresno, Cal.
Augusta, Georgia.	Buffalo, N. Y.
Macon, Georgia	Syracuse, N. Y.
Atlanta, Georgia	Albany, N. Y.
Mobile, Alabama	Kansas City, Mo.
New Orleans, La.	Daytona, Florida
Baton Rouge, La.	Cleveland, Ohio
Beaumont, Texas	Chicago, Ill.

The important additional purpose which these landing fields will serve, and to which reference was made a little while ago, is this: We desire to keep together as far as possible, at least to keep in touch as far as possible with the officers, trained pilots, mechanics, etc., who have had service during the war. These municipal landing fields it is believed will serve the useful purpose of centering the interest of the classes of men just referred to and the aim of the Air Service is to establish in each one of the communities, where the landing field is maintained, a reserve unit which can then be provided with the facilities for instructions and practice in flying, observing, care and repair of ships, and which would be so organized as to furnish a unit for service in case of emergency. This I consider one of the most important phases of this whole proposition of the municipal flying fields, and the co-operation of every one concerned is earnestly requested.

The Sturtevant Engines

(*Continued from page* 538)

perature around all parts of the cylinders. The water pump has been so designed as to permit easy adjustment of the packing gland.

Thermostat

The Sturtevant Thermostat is arranged to control the temperature of the cooling water. This very important device has been worked out after many months of experimentation by Sturtevant engineers. It is mounted as an integral part of the engine. The Sturtevant Thermostat insures a constant engine temperature regardless of altitude and atmospheric conditions, thereby producing a perfect running engine at all times. "Freezing up," a not uncommon occurrence with aeroplane engines, especially at high altitudes and in long glides, is prevented by the thermostat. The significance of the above will be readily appreciated by those who fly and who know the difficulties encountered. The Sturtevant Company is the first manufacturer of aeroplane engines to work out successfully and adapt a thermostat for water temperature control.

Tachometer

A tachometer which gives accurate readings and which shows no vibration of the needle, is supplied either with or without a positive revolution counter for checking purposes.

Self Starter

The engine has been arranged to permit of the application of an efficient air starter if desired. Any other suitable starter may be applied.

Laugh and the World Laughs With You

Atlantic City Convention Has Aroused Nation-Wide Interest in Aeronautics

JE SHED WEEKLY BY THE AERIAL AGE COMPANY, INC., FOSTER BUILDING, MADISON AVENUE AND FORTIETH STREET, NEW YORK CITY

We urge airplane manufacturers to compare the performance of AC Aviation Plugs with the performance of other makes of plugs. The United States Government staged a series of such competitive tests which resulted in the adoption of AC Plugs as standard equipment on all Liberty and Hispano-Suiza airplane motors during the war. As you well know, most makers of fine motor cars have used AC Spark Plugs for standard equipment for years.

VOL. IX NEW YORK, JUNE 2, 1919 NO. 12

MONTH'S CONVENTION AT ATLANTIC CITY HAS AROUSED NATION-WIDE INTEREST IN AERONAUTICS

THE month's Convention and Exposition, held under the auspices of the Pan-American Aeronautic Federation, Aero Club of America, and Aerial League of America, has aroused nation-wide interest in aeronautics, and has been a very great stimulous in showing to business interests and government departments ways and means of utilizing aircraft effectively in peace time.

Aviation Insurance

CONCLUSIVE indication of the arrival of aeronautics in the commercial stage is given by the recognition that has come from several of the representative insurance companies to-day writing all kinds of insurance on aeroplanes, passengers and pilots, according to speakers talking on the subject of aviation insurance before the sessions of the Second Pan-American Aeronautical Convention.

Lieutenant Charles H. Payne, U. S. N., who has written insurance on all the planes now operating from the local airport and other flying stations here in checking up figures on the record accomplished in the reduction of accidents, declared that from 1908 to 1913, both in military and civil aeronautics, 60 per cent. of the casualties were due to the collapse of the plane, as the result of faulty construction, while from 1913 to date, only 2 per cent. of the casualties were caused by the collapse of the plane.

Of present-day accidents, according to the insurance expert, approximately 40 per cent. are due to tail-spins entered into too close to the ground or by inexperienced pilots who are unable to extricate themselves; 25 per cent. through lack of judgment in landing, 10 per cent. to forced landing caused by motor trouble, 2 per cent. by fire, 2 per cent. by collapse of the planes, and 22 per cent. by lack of judgment in various maneuvers by pilots still in training.

Among the stipulations in the aviation insurance is a clause which declares damage must be in excess of $200 to the plane before the underwriters become liable, this being done because the snapping of a strut or some small part of construction is common. Predictions were made by Lieutenant Payne that inside of six-months aeroplane insurance will be even cheaper than automobile, because of the safety establishment of fields with devices aiding safe landing under adverse conditions, and the mapping out of airways and air routes.

Mrs. May Brown-Dietrich, daughter of ex-Governor Brown, of Maryland, who has been flying at the Atlantic City Airport, with Eddie Stinson. Mrs. Brown-Dietrich, who offered the "Women's Flying Trophy", was the first woman to loop-the-loop six times in succession and to secure an aviation insurance policy

The Second Pan-American Aeronautic Convention
Night Flying Problems

REALIZING that night flying is to play a big part in the impending commercial era of aircraft, the second Pan American Aeronautical Congress turned the searchlight of science on the illumination of air ports. Taking advantage of the convention here of the National Electric Light Association, the aeronautic authorities held a special conference with the electrical wizards, who were headed by A. E. Ryan, the man who made the Pan American Exposition at 'Frisco a "brilliant" success. Major Thomas Baldwin, who is in charge of the port here, led the aero heads.

Co-operative action toward special tests in working out standardization of aviation field illumination were programmed by the conference, the experiments to be made at the great Atlantic City Air Port immediately. What conclusions are reached will serve as the sample for the fields and ports throughout the country.

The problem as it was brought out at the conference, is essentially different from that developed in the marking of fields for war purposes. Under the latter conditions the question was one of concealment by camouflage to prevent discovery of the aviation areas by the enemy while the question now under consideration is one of "antiflage," or making the fields distinctive. Even at the aviation training bases in this country there were no standard plans of marking the land points at night, a simple flare being the only method followed.

The plan under consideration by the conference had to do with the illumination of the terrain to a sufficient degree to bring out all its features—the runways, ground hazards, wires, buildings and the sort, together with the limitations of the field so that the flyers may know just how much elbow room they have.

One of the hardest problems will be that of making the air port illumination contrast with the lighting of cities, especially where the fields are located within a populous centre. The plan suggested to cover this was the tinting of the field illumination and the establishment of aerial "lighthouses" that would flash signals in much the same manner as the coast system works out to water navigators. Each field will have its own code, so that the sky navigator by referring to his chart can discover his position as easily as the skipper of watercraft. It is also proposed a microphone arrangement in the lighthouses so that the "keeper" constantly on duty, may detect the cloud mariner when he comes within a given radius and be able to signal directions by wireless as to where to land and whether or not the park is "clear" for the drop.

One of the novel "range finders" suggested as a double-circle arrangement—one illuminated circle smaller than the other and giving the flyer his range when the little disc shows as the centre of the larger like a bull's-eye. Another plan consisted of sixteen lines converging to a common centre operating automatically from a wind vane, the line lighting up in the direction of the wind and the two lines on either side of this long and the opposite side of the centre also lighting, making an arrow formation.

All the illuminants on the ports will be worked from the indirect system, so that there will be no glare in the eyes of the pilots. The line system of lighting for the wind direction will be from pits so that there will be no obstruction on the surface of the field.

The wires will all be buried, and in lighting any buildings the illumination will be by projected lights from outside points in order to cut down the fire hazards, especially in hangars for dirigibles.

The lighting of the aeroplanes as an additional factor considered as a safety plan. It is proposed to have the planes carry lights port and starboard the same as any other vessel, and tail lights to give other flyers the tip on direction. Powerful projected lights beneath the aeroplane that will enable the pilot to skim over a field and by playing his lights on the terrain below discover just what is there, will be perfected.

Inherent Versus Mechanical Stability

THE aeroplane that will immediately be available for commercial, sporting and every-day purposes will not be the machine that most nearly follows the lines of a bird in construction, but rather the plane that is equipped with automatic devices that constantly check up the stability, meeting bumps, air pockets and other atmospheric disturbances as they start, and adapting the machines to them before they have actually been felt by the pilot.

This was the declaration of Morris M. Titterington, of the Sperry Gyroscope Company, speaking before the second Pan-American Congress. Mr. Titterington told of many startling weapons of the air made possible through the use of automatic stabilizers, which showed the great advantage over machines not so equipped.

"In working out inherent stability," said Mr. Titterington, "attempt is made to make the plane stable by shaping its parts and spacing them in such a manner that it will tend to fly in a horizontal plane and along a straight line.

"Some inherently stable planes fly wonderfully well in still air, banking automatically on turns and maintaining their longitudinal angle in fine style, but they are invariably difficult to control in rough weather, rolling and pitcihng violently on encountering slight disturbances. The rolling, pitching and turning movements are so interconnected that the plane cannot roll without also turning and pitching or turn without rolling. This makes it necessary to work two or more controls when an inherently stable machine encounters a gust, while with the ordinary type the operation of one control would be sufficient. Their rolling and turning movements are particularly strongly connected. In fact, they lose nearly all their inherent stability if held right on the course by the pilot operating the rudder.

"While I do not wish to be quoted as saying that there is no future for inherently stable machines, I believe it to be a fact that the disadvantages inherent in such machines are so great that their field is very limited. As machines are made larger they will naturally be steadier in flight, but no planes have been yet made that will fly successfully in rough air without being controlled by the pilot or by some mechanical stabilizer, and from the very nature of the problem I do not believe such planes can be produced. Man has been making boats from the very dawn of history, but he has not yet made one that would go steadily through a rough sea, notwithstanding the fact that this is a much simpler problem than making an aeroplane fly steadily in disturbed air.

"It is certainly desirable that a plane have a small amount of stability so that it will right itself when upset and tend to remain in the correct flying position, but too great a stable tendency is most decidedly undesirable.

"We now come to the consideration of mechanical stabilizing apparatus, that is, apparatus which might be called automatic pilots, as they control the plane by operating the control surfaces in much the same way that the human pilot would operate them. There have been innumerable inventions and suggestions along this line.

"It is not possible for even the most expert pilot to tell that his plane is encountering a disturbing force until the plane is actually tilted. By this time it has acquired some momentum, and a considerable movement of the controls is necessary to bring it back to its correct position. The advantage of the automatic pilot over manual control is that it detects the slightest tilt of the plane and has already moved the control surfaces to correct it long before a human pilot would notice that the plane was tilting. The result is that the control surfaces are moved only a slight amount as compared to the amount the pilot would move them, and the tilt of the plane is only a fraction of what it would be with manual control.

"There is another use to which an automatically controlled plane can be put that is destined to be of tremendous importance in future warfare, if the new League of Nations does not succeed in preventing wars. I refer to the aerial torpedo, which has been briefly mentioned by the Secretary of War. The idea is to equip a cheaply constructed aeroplane with automatic control, load it with all the explosives it can carry and direct it toward the enemy. Special apparatus is used to dive the machine when it reaches the target. I cannot give much information regarding the progress which has been made with the aerial torpedo, as that would have to come from the Government departments concerned in the work. I think it will be permissible, however, for me to tell of some experiments carried out by the Sperry Gyroscope Company long before our entry into the war.

"A flying boat was equipped with automatic control and other special apparatus. The boat was headed either directly at the target or to one side or the other, depending upon the direction of the wind. The automatic pilot was adjusted so as to climb the machine very slowly. The throttle was then opened and the machine released. It would get off the water automatically and climb to a predetermined altitude, where it was leveled off by an automatic altitude control. It would then fly level until reaching the target, where it would be volplaned automatically by a device which I am not at liberty to describe. In these tests, a pilot went along with the machine to bring it back to the starting point, but, of course, did not touch the control until after the plane had reached its destination. The accuracy of fire was found to be very remarkable, in view of the uncertainty of the air currents.

"There have recently been some published reports of a radio controlled torpedo which was gotten out by the French Government. This torpedo was controlled by radio from another plane several miles away, and in experimental flights was made to fly over different towns behind the enemy's lines.

These torpedo planes were equipped with the Sperry automatic pilot. It is thought if the war had lasted a short while longer the aerial torpedo would have become a very formidable weapon of warfare.

"In peace time there is no doubt that the automatic pilot is destined to be of inestimable value in making flight safe and profitable."

Aerial Laws and Regulations

THE Joint Committee on Aerial Laws and Regulations of Air Traffic of the Second Pan-American Aeronautic Convention presented a report to the convention urging that Congress be asked to create an Aircraft Board in the Department of Commerce to supervise aerial transportation. The report includes the text of proposed temporary regulations to govern aerial navigation regulations that have been indorsed by President Wilson, Secretary of War Baker, Secretary of the Navy Daniels, Secretary of Commerce Redfield and Dr. Charles D. Walcott, the chairman of the National Advisory Committee on Aeronautics.

The text reads:

"An emergency has raised in relation to the establishment of rules and regulations to govern aerial navigation within the United States and its dependencies.

"1—At the present time there is no authority for the establishment of rules and regulations to govern aerial navigation in the United States and its dependencies except local laws passed prior to 1914 in the States of Massachusetts and Connecticut.

"2—The War Department alone now has for sale several thousand aircraft of various types which, if put upon the market, will be purchased largely by amateurs, and in the absence of Government rules and regulations it is highly probable that many accidents will occur and much legislation ensue.

"3—There is also a probability of complications, especially in matters of smuggling, arising by unlicensed, irresponsible aircraft crossing the borders between the United States and both Canada and Mexico.

"4—At the present time the Joint Army and Navy Board of Aeronautical Cognizance has been issuing licenses to pilots as a war emergency, but without assuming any responsibility as to qualifications of pilots or air worthiness of the aeroplanes.

"It is held that the power of this military board ended with signing of the armistice, Federal Judge Walter Evans having handed down a decision on April 3rd to the effect that the war ended legally when President Wilson in his address before Congress on November 11, 1918, referring to the defeat of Germany said: 'The war thus comes to an end.'

"The Aero Club of America has for the past ten years been issuing certificates and contests as provided by the rules of the International Aeronautic Federation which governs all aerial contests."

The Joint Committee urges that Congress be asked to create an Aircraft Board in the Department of Commerce, as provided in the following bill, the adoption of which is urged:

1.—Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled. That all persons not in the military or naval service of the United States are hereby prohibited from operating any aeroplane, balloon, or other invention or device used for navigating the air, without first obtaining a license from a board appointed by the Secretary of Commerce as hereinafter provided.

Sec. 2. That the Secretary of Commerce is authorized and directed to appoint three persons who shall be known as the Aircraft Board and who shall have power to issue licenses for the operation of machines or other devices which traverse the air for commercial or other purposes.

Sec. 3. That the Aircraft Board shall consist of three men, two of whom shall have had practical experience in the construction and operation of aeroplanes, and one of whom shall have practical knowledge of the construction and operation of a dirigible balloon. The Secretary of Commerce shall designate one of the board as chairman, who shall receive a salary of $4,500 a year; the other members of the board shall receive a salary of $4,000 a year each. The Secretary of Commerce shall provide offices for said board; and such clerical assistance as may be needed shall be employed with the approval of the Secretary of Commerce.

Sec. 4. That it shall be the duty of the board to arrange for and conduct examinations of persons who apply for licenses to operate aircraft machines, balloons, or other similar devices, and a license shall not be issued to any person who, in the opinion of the board, is not qualified to operate the machine or other aircraft device covered by the license for which he has applied. The board may designate persons to conduct examinations at distant points or for the convenience of applicants for licenses. Persons so designated must have qualifications similar to those required of members of the board; compensation for the examiners so designated will be fixed with the approval of the Secretary of Commerce and in no instance shall it exceed $2,500 annually for any examiner.

Sec. 5. That traveling and subsistence expenses shall be allowed on the same basis as that provided in existing law for officials of the Department of Commerce. The sum of $50,000 or as much thereof as may be necessary is hereby appropriated out of the money in the Treasury not otherwise expended to carry out the purposes of this act.

Sec. 6. That the Aircraft Board hereby created is authorized to issue temporary or probationary licenses until such time as a plan for holding examinations is provided and an opportunity given to applicants to try said examinations. When, however, a sufficient time has elapsed and ample opportunity given to hold the said examinations conducted by the Aircraft Board and for any applicant to try such examinations, it shall be unlawful for any person not in the military or naval service of the United States to operate an aeroplane, dirigible balloon, or other device for navigating the air, and any person who operates an air device or invention in violation of the terms of this Act shall be guilty of a misdemeanor and liable to a fine of not to exceed $100 or six months' imprisonment, or both, for the first offense, and imprisonment for not to exceed six months for any subsequent offense.

In anticipation of the adoption of such a measure the Aero Club of America, the Aerial League of America and the Atlantic City Aero Club have established a system of registration of aircraft and aviators at the Atlantic City Airport and are developing a system of registration and clearance papers for aircraft and air pilots and passengers.

The following authorities are members of the Committee in charge of aerial regulations: Messrs. Alan R. Hawley, Henry Woodhouse, Albert T. Bell, W. W. Young, Colonel Jefferson de Mont Thompson, Thomas F. Powers, W. W. Niles, Colonel Charles Elliott Warren, Augustus Post and Major Reed C. Landis, son of Judge Landis and second ranking American Ace.

Aerial Acrobatics

Sensational acrobatics that made even Eddie Stinson, heretofore the most finished of the air pilots who have been amazing the throngs at the Atlantic City Airport, hold his breath from his "orchestra seat" a little off to one side in his own aeroplane, featured when Lt. Omer Locklear, former Army sky-skipper, mounted five times from one aeroplane to another by means of a rope ladder swinging clear in the air. Crowds below, who had been told that the lieutenant, who was the first man to jump from a plane above to the one underneath, would attempt to reverse the order, could see him standing upright on the upper wing and reaching for the ladder as one machine maneuvred by Lt. Melvin Elliott hovered over a second piloted by Lt. Shirley Short.

But it was Eddie Stinson who brought the real story of the maneuvres to the ground. "I have seen some nice balancing aad daring driving of aeroplanes but those two pilots and Lt. Locklear showed me something new today," declared Stinson, who himself was chief of aerial acrobatics in southwestern army flying fields throughout the war.

"While Lt. Locklear was swaying back and forth on top of the Short machine, Lt. Elliott swooped down from above, and so much confidence did those two drivers have in one another that the machines actually kissed one another, making it necessary for Lt. Locklear to drop and stretch out flat on top of the plane. Yet with cool daring he flipped upright again and grabbed for the ladder as they pulled away. It was the most remarkable aerial stunt. It was one of the most daring bits of game flying I have ever seen." Eddie had been up with a photographer, trailing the two planes throughout the trips.

Crowds below knew nothing of the aerial kiss but they saw the machines so close together that they looked as one skooting through the sky over a thousand feet in the air. Lt. Locklear, baffled by the wind, made three desperate trips across the field standing up on the wings of the aeroplane while the throngs below nervously clutched one another fearing that he would be dashed to death at any instant. Just to show that he was still perfectly cool he proceeded to climb all over the plane as it swooped down within a hundred feet of the ground, once hanging by a precarious hold to the skid at the extreme tip of the right wing and again hanging by his knees from the axle of the landing gear beneath the fuselage, permitting the wind to swing him back and forth head down like a pendulum.

The intrepid aviators demonstrated that it would be possible to change to another plane if the one you are travelling on catches fire.

Some of the Exhibitors

Among the exhibitors at the Second Pan-American Aeronautic Convention at Atlantic City who featured display booths in the Aeronautic Hall of the Steel Pier were:

The Curtiss Flying Station, of Atlantic City, represented by Messrs. Harold Kinne, A Livingston Allen and J. M. Reid, which displayed the latest type of Curtiss two-passenger tournig aeroplane, beautifully finished with nickled instruments and fittings and with the fabric removed from one wing and one half the fuselage throughout its length for the instruction of interested visitors; a working model of the largest wind tunnel in the world; drawings, photos and models of different types of Curtiss aeroplanes, seaplanes and flying boats; and the latest Curtiss motors; the Curtiss 6-150 h.p. and the Curtiss 12-400 h.p., until recently known as the K6 and K12 types, respectively. The local Curtiss station wished also to exhibit the Curtiss MF flying boat—3 passengers' capacity and equipped with the Curtiss motor, but the crowded condition of the exhibition hall prevented this. Interested persons were directed to the flying field, where the flying qualities of this "boat" were demonstrated to the interested persons.

The American Propeller and Mfg. Co., of New York City, represented by Messrs. A. B. Streeter and W. W. Christian, which displayed the Inland Piston Rings.

The Brunswick-Balke-Collender Co., of Chicago, represented by Mrs. M. Bull, which displayed different types of the all-rubber propeller which the manufacturers believe will defeat the present effect of rain and sand on the rapidly revolving air screw and which is now undergoing tests for the United States Army and Navy.

The Abercrombie and Fitch Co., of New York, represented by Mr. A. S. McDade, which exhibited an assorted line of aviation clothing and equipment.

Miss Mason's Castle School, of Tarrytown-on-the-Hudson, a school of instruction in aviation for women, represented by Miss Elsie Toboldt.

The Champion Spark Plug Co., of Toledo, O., represented by Mr. George F. French, which displayed the Champion spark plug, the component parts of the plug and a set of colored views illustrating the procedure of manufacture in the company's factories.

The Splitdorf Electrical Co., of Newark, N. J., represented by Mr. Daniel Walls, which exhibited Splitdorf magnetos, instruments and spark plugs and by cleverly arranged devices displayed the manner in which the spark plugs ignite the charge in the cylinder of the gas motor. Two features of the Splitdorf exhibit that were of particular interest to visitors were a Hispano-Suiza motor equipped with Dixie magnetos and Splitdorf spark plugs and a large Victory Loan V that crackled and blazed with the continuous firing of spark plugs embedded in its surface.

The Triplex Safety Glass Co., of New York, displayed Triplex wind shields and aviator's goggles. The Sperry scopic Unit, Mark 1 Mod. E., the Sperry compass, speed indicator, barograph, altimeter, etc. The Aircraft Instruments and Supplies Co., Inc., of Atlantic City, displayed various instruments, including the Shotwell Electric Weather Vane and the Charles Lane Poor Line of Position Computers. These exhibits were in charge of Lieut. Edgar Garland, R.A.F., who also represented the Renault Motor Works, of France, which exhibited the Renault 12 cylinder 350 h.p. motor.

The Aeronautic Library, Inc., of 299 Madison Ave., New York City, represented by Miss Josephine Dunn, displayed aeronautic text books and other books on Aeronautic subjects. The aeronautic publications, *Flying,* AERIAL AGE WEEKLY, and *Air Power,* were represented by a pictorial display.

Other exhibits of great interest were the gallery of French Aerial War Paintings, by Lieut. Henri Farre, official painter for the French army during the war, the aerial war paintings of the American naval aviator, Lieut. Ruttan, and the trophies that were competed for during the convention.

Honor 123 Flyers Killed in Service

Posthumous honors for the 123 officers and enlisted men attached to the marine aviation force and United States naval officers of the Aviation Corps who lost their lives in the service of their country during the war were awarded by the Second Pan-American Aeronautical Congress at impressive services on the Steel Pier.

There were eighteen States represented on the list of the marine force and twenty among the heroes of the naval corps. Diplomas were drawn by the Aerial League of America and forwarded to the mothers or next of kin by the convention through Secretary Post of the Aero Club and the Aerial League of America.

The Memorial Committee consisted of Rear Admiral Robert E. Peary, Alan R. Hawley, Capt. Robt A. Bartlett, Capt. Granville A. Pollock, Rear Admiral Bradley Fiske, Major Reed Landis, Albert T. Bell, Thomas F. Powers, John Hays Hammond, Jr., Col. Lester Jones, U. S. A. M. S., Henry Woodhouse, Joseph A. Steinmetz, K. M. Turner, W. W. Niles, G. Douglas Wardrop and A. S. Abell 3d.

The awards read: "This diploma of honor of the Aerial League of America is awarded ——— in recognition of the patriotic service which he rendered to the cause of humanity and civilization in the service of the United States during the war," and bore the signature of League President Robert E. Peary.

Among the prominent birdmen attached to the Marine Aviation force honored were: Major D. B. Roben, Big Rapids, Mich; Lieut. W. S. Poague, Chicago; Lieut. C. C. Barr, Upper Montclair, N. J.; Lieut. Thomas J. Butler, New Rochelle, N. Y.; Lieut. Edward Cain, Catonsville, Md.; Lieut. Duncan H. Cameron, Englewood Pa.; Lieut. Donald B. Cowles, Carrington, Conn.; Lieut. Marcus A. Jordan, Washington, D. C.; Lieut. Harvey C. Norman, Davenport, Ia.; Lieut. Melville E. Sullivan, Richmond, Va.; Lieut. William R. Julian, Berry, La.; Sergt. Emil Rosenfield, Miami, Fla.; Sergt. William P. Cammon, Cleveland, O.; Sergt. Glenwyn Vorhauer, Sigourney, Iowa; Corp. David F. Price, Boscobel, Wis.; Corp. Wal-

The Curtiss Model H-A Hydro, the Fastest Seaplane in the World

The News of the Week

Stefansson and Wright Discuss North Pole Flight

Dayton, Ohio, May 22.—For the purpose of discussing with Orville Wright the possibility of using the aeroplane for North Pole trips, Vilhjalmur Stefansson, international explorer, paid a visit to Wright at the latter's home here on May 22.

Stefansson declared he believed it possible to construct a special type of aeroplane that would carry a party of explorers to the field of study at the north pole. He plans, if satisfactory arrangements can be made, to attempt such a trip during this year or the first of the coming year.

Col. Hall Given D. S. M.

Washington, D. C.—Award of the Distinguished Service Medal to Elbert J. Hall, formerly a lieutenant colonel in the Signal Corps, for his work in designing the Liberty motor, was announced recently by the War Department.

Two Aerial Forest Patrol Routes Start June 1

Washington, D. C.—Two routes in the patrol of National Forests by Army aeroplanes, to give early warnings of fires in the forests, have been arranged by the War Department and the Forest Service, United States Department of Agriculture. The routes will be operated from Mather Field, near Sacramento, and will be placed in operation June 1, on the same day as two routes to be operated from March Field near Riverside, Cal.

The first route from Mather Field will cover the northern Eldorado and Tahoe Forests on the valley side of the Sierras. It will start from Mather Field and proceed to Placerville, Colfax, Nevada City, Strawberry Valley, and Oroville, where the planes will land at a field now available. This route will be covered in the morning of each day, and return trips will be made in the afternoons.

The second route from Mather Field will cover the southern Eldorado and Stanislaus Forests. Starting from Mather Field the route goes to Placerville, Grizzly Flat, Big Trees, and to a landing near Sonora or Tuelumne. This route will be covered in the morning and return trips will be made in the afternoons. Both of the Mather Field routes have a round-trip length of about 150 miles.

Forest Service reports tell of a successful trial patrol undertaken recently. No difficulty was experienced in detecting fires in heavy timber at elevations of 6,000 to 10,000 feet.

Washington to New York in a Hundred Minutes

Mineola, N. Y.—Captain Leroy Charles and Lieut .John Roullet made a flight on May 17 in a DeHaviland 4 from Washington in an hour and forty minutes.

Victory Loan Fliers Covered 19,000 Miles

The three "companies" of the "Victory Loan Flying Circus" ended 30-day tours at their home stations, after "playing" in 88 cities, in 45 States, and covering in "one-day stands" circuits totaling 19,124 miles.

Navy Plans Larger Aeronautic Program

Washington, D. C.—The Navy Department is so enthusiastic over the results of the first attempt at a transatlantic flight that broad plans are being prepared for expansion of the aerial program. In brief, these points are:

1. General development of aircraft necessary for the fleets, including the enlargement of seaplanes and observation balloons.

2. Extensive experimentation in the laboratory and by flying tests for obtaining improved planes of both heavier than air and lighter than air types, for service in home waters and overseas.

3. Development of the rigid, lighter than air machines (the Zeppelin type), as well as the dirigibles of the C-5 type.

4. Perfection of the coastal aerial patrol service.

A prominent naval official said recently that one of the most important conclusions reached as a result of the flight to the Azores was the practicability of the multi-engine seaplane. The results which had been attained, he said, made it evident that the development of larger and more durable planes which would be almost as seaworthy as a vessel of considerable proportions was feasible and that in the opinion of the navy experts there was no reason why such a seaplane could not be made of sufficient strength to carry at least as many as eight engines.

The advisability of constructing huge lighter than air craft has resulted in recommendation of a large appropriation, said to be $10,000,000, for experimental work on large types of dirigibles.

Curtiss Plane Flies 500 Miles at 2 Miles Per Minute

Portland, Me., May 20.—Major M. H. Gilksen, U. S. A., flying a Curtiss advanced training plane, arrived here on May 20 after a non-stop flight from Mineola, L. I. He made the distance, about 500 miles, in four hours and ten minutes. He was scheduled to stop in Boston, but was going so well that he continued to Portland.

Major Gilksen is accompanied by H. M. McGraw, electrician. Weather conditions were good and the flight was uneventful.

Secretary Crowell Sails on Aeronautic Mission

Assistant Secretary of War Benedict Crowell sailed on May 22 on the transport Mount Vernon with a delegation which will study aviation abroad for three weeks or longer. With the Assistant Secretary were his aid, Colonel James A. Blair, U. S. A.; Captain Henry C. Munson, U. S. N.; Howard E. Coffin, of the counil on National Defense, S. S. Bradley, of the Manufacturers' Aircraft Association, George H. Houston, President of the Wright-Martin Aircraft Company, and Charles M. Keyes, Vice President of the Curtiss Aeroplane and Motor Corporation.

This mission is going abroad for the purpose of learning what Great Britain, France and Italy have done since the armistice was signed to develop a peace-time program for civilian aviation.

On arriving in France they will report to President Wilson and expert advisers will be assigned to the mission. Admiral Knapp, U. S. N., an admiralty expert, and Colonel William Dunwoody, chief of the air service supplies of the American Expeditionary Forces, will be among those called to advise the mission.

New Films of Air in Motion Abuot Aerofoils Will Aid in Design

Washington, D. C., May 22.—A series of films of remarkable value to aircraft engineering were taken under the supervision of Colonel Rutherford B. Harts at Bolling Field under the auspices of the Division of Military Aeronautics and the Inventions Section of the General Staff showing the movement of air in motion. So important is this discovery considered

The Curtiss LR1 triplane with a Curtiss OX engine

that an effort was made to deliver them to Secretary Crowell aboard the transport Mr. Vernon by aeroplane.

Three miles of film were used in making these photographs of air in motion across aerofoils, or wings, of aeroplanes. They prove that the element of rarefaction, which produces the lifting power of an aeroplane, is not continuous, but is exerted in intermittent or pulsating air waves. These power waves have a period of generation, development, climax of lifting power, and speedy collapse, with a resultant aerial undertow. The photographs show plainly that for over 30 per cent. of the time of flight no flying power whatever is exerted on the wings of an aircraft by the air flow produced by the air screws.

The camera is the invention of Fairfax Naulty, of New York.

War Planes Making Fast Cross Country Flights

Washington, D. C.—In connection with the War Department's recruiting campaign, several speedy cross-country flights have been made.

Col. G. C. Brant and Lt. H. Birkett en route Houston, Tex., to New York, flew from Houston to Belleville, Ill., in a De Haviland 4, distance 720 miles, in 453 minutes on 17th.

Lt. Solomon F. Baker flew from Mt. Clemens, Mich., to Jackson, Mich., 94 miles, in 105 minutes.

Using a Curtiss JN4H, Lt. Geo. H. McKay completed a flight from Belleville, Ill., to York, Nebraska, a distance of 500 miles, in 345 minutes.

Bad weather held the flyers at Belleville until May 20, when they flew to Dayton, O., a distance of 310 miles, in 210 minutes. They left Dayton May 22 and flew to Washington, Pa., 240 miles, in 120 minutes. The last leg of the journey was made from Washington, Pa., to Washington, D. C., 235 miles, in 127 minutes.

The 1,505 miles between Houston and Washington have been covered in 910 minutes.

Queens Borough Offers Government Landing Fields

The Queens Borough Chamber of Commerce (New York City) has offered to the Government the services of its manufacturing and industrial committee, Ray Palmer, chairman, in securing necessary landing fields for both aeroplanes and seaplanes. The attention of both the Secretary of War and the Secretary of the Navy has been called to the advantage of Queens for the location of landing fields. There are many large, level undeveloped areas about both Flushing and Jamaica bays. There are facilities—trolleys, railroad and elevated lines—for rapid transit to Manhattan, if for any inexplicable reason an aviator landing in Queens should desire to cross the bridge.

Marconi Wins Exclusive Right to Fleming Valve

A decree signed by Federal Judge Mayer on May 21 gives to the Marconi Wireless Telegraph Company of America the exclusive ownership of a patent granted Nov. 7, 1905, to John Ambrose Fleming. The decree excludes the Atlantic Communication Company from all rights in the invention. The court appointed Ex-Judge E. Henry Lacombe a special master to ascertain the amount of damages to be assessed aginst the defendant company. This device, in improved form, is used for radio telephone communication.

Bureau of Standards Develops Spark Plug Porcelain

Considerable trouble has been caused in aeroplane engine work through the breaking of the central electrode of sparkplugs. An investigation of this problem was undertaken by the Bureau of Standards at the request of the Bureau of Aircraft Production. The results are given in Aeronautic Power Plants Report No. 35, which shows that in many cases the cement used to hold the nickel electrode wire in the porcelain is of such a nature that it rapidly eats away the wire through oxidization, when exposed to the high temperature of the engine cylinder. A cement composed of silicate of soda and raw kaolin has been found to give the least trouble in this respect.

In cases where the cement holds the wire firmly in the porcelain the latter often cracks when subjected to heat due to the difference in the coefficients of thermal expansion of the wire and the porcelain. The breaking of the porcelain does not seem to be due to leaky sparkplugs, as has often been supposed to be the case.

On account of the difficulties attending the use of any form of cement between the porcelain and the central electrode, the elimination of the cement and the use of a mechanical seal at the top of the porcelain is greatly to be desired. In such a plug only a porcelain strong enough to withstand the resulting stresses safely should be used. The porcelain recently developed by the Bureau of Standards is believed to meet these requirements.

Civilian Flying Licenses Issued by the Joint Army and Navy Board of Aeronautic Cognizance

Washington, D. C.—The following civilian licenses have recently been issued:

License No.	Issued to	Address
343	Service Aviation Training & Transportation Company,	Wabash, Ind.
387	Tony Barone,	Fort Worth, Tex.
388	H. W. Hanchette,	Wort Worth, Tex.
389	Clarence F. Cato,	Beaumont, Tex.
463	Francis B. Towle,	Larchmont, N. Y.
464	Donald Gifford Vande Water,	Washington, D. C.
465	Howard J. Ludington,	Holley, N. Y.
466	G. W. Shaw,	Caribou, Me.
467	Laurence L. Russell,	Wilmington, Del.
468	Adolphus R. McConnell,	Knoxville, Tenn.
469	Earl Kenneth Campbell,	Strawberry Pt., Iowa

Curtiss R-4 mail plane equipped with 12 cylinder Liberty motor

Dirigible Lands its Passengers on Cleveland Hotel Roof

Cleveland, May 23.—For the first time on record a vehicle of the air was brought to a convenient stop in the heart of a large city when a dirigible balloon landed on top of a prominent hotel here this evening to permit two of its five passengers to alight. The 160-foot dirigible, the A-4 which has a gas capacity of 95,000 cubic feet, after seven attempts landed on a specially constructed platform 30 by 30 feet.

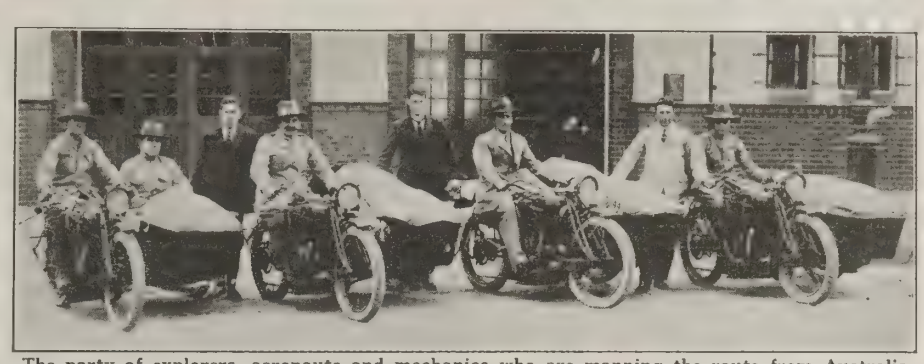
The balloon was piloted by James Shade from the Wingfoot Lake Naval Air Station near Akron. Ralph H. Upson, winner of the last international balloon race at Paris in 1913, and Major C. H. Maranville, flying instructor at the training station, were among the passengers.

Raw Materials for Aeroplanes

Some idea of the quantity of wood necessary for aeroplane and propeller construction may be obtained from the following table of actual deliveries, as published in a British journal:

	Board feet.	Totals.
Spruce.		
U. S. Army	25,472,000	
U. S. Navy	8,667,000	
England	36,877,000	
France	22,929,000	
Italy	9,147,000	
		103,092,000
Douglas Fir.		
U. S. Army	19,193,000	
U. S. Navy	21,746,000	
England	21,226,000	
France	9,460,000	
		71,625,000
Port Orford Cedar.		
U. S. Army	30,000	
U. S. Navy	1,926,000	
England	2,57,000	
		4,513,000
Mahogany, Central American.		
U. S. Army and Navy	4,524,000	
Allies	4,197,815	
		8,721,815
Mahogany, African.		
U. S. Army and Navy	269,000	
Allies	200,935	
		469,935
American Black Walnut.		
U. S. Army and Navy	2,408,000	
Allies	2,096,000	
		4,504,876
Quartered White Oak.		
U. S. Army and Navy	308,000	308,000
Cherry.		
U. S. Army and Navy	618,000	618,000
Ash.		
U. S. Army and Navy	87,000	
Allies	33,565	
		120,565
Birch.		
U. S. Army and Navy	663,000	663,000

In addition to wood, it was found necessary to maintain strict supervision over the production of aeroplane and balloon fabrics. Of this class of material there had been produced to November 11, 1918, 3,187,000 yd. of linen; 7,000,000 yd. of cotton aeroplane fabric; 2,647,000 yd. of balloon fabric.



Book Review

How An Aeroplane Is Built: compiled by Stepney Blakeney.

This is a valuable publication for the mechanic. The author—a practical mechanic—knows and explains the best workshop methods and comprehensively describes in this volume every item down to the last rivet.

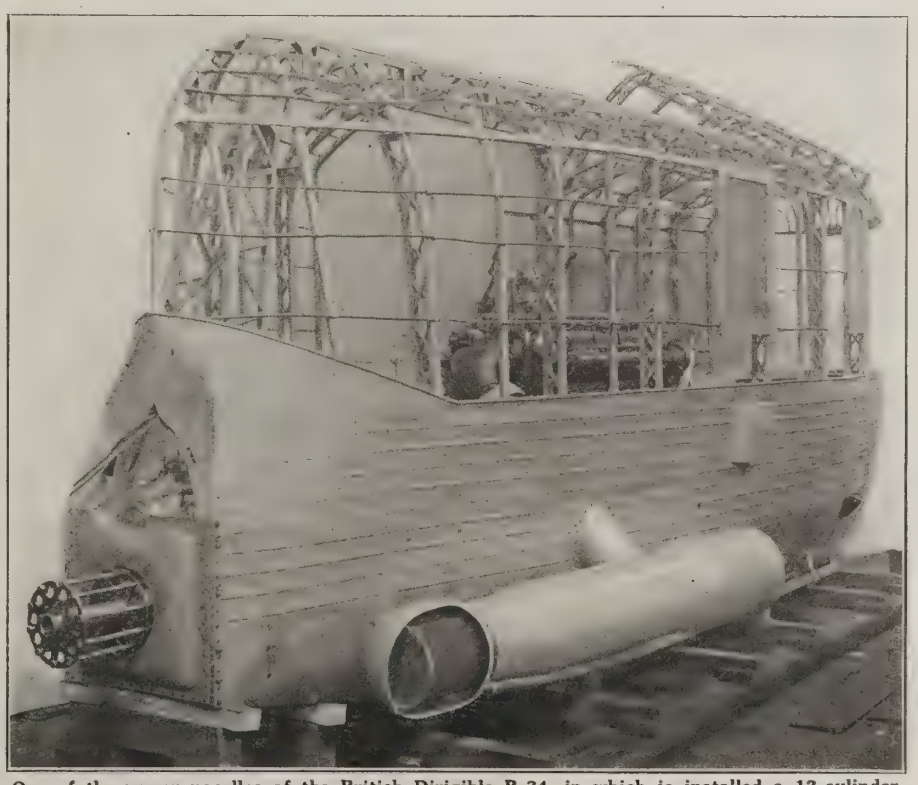
Contents: Erecting the Fuselage, Wing Structure and Wing Covering, Doping, Aileron Construction, Bolt Making, Lift Plates—The Tail Plane, Checking the Angles of the Wings, Control Levers, Tail-Skid Fittings—Strut-End Fittings, Engine Plates—Petrol Tanks, Completing the Centre Section, Doping, Varnishing and Pigmenting, Erecting the Machines, Odd Jobs and General Examination.

This publication can be purchased at *The Aeronautic Library, Inc., 299 Madison Avenue, New York City.* Price $1.35 post paid.

The party of explorers, aeronauts and mechanics who are mapping the route from Australia to England

ENGLAND TO AUSTRALIA AIR ROUTE BEING SURVEYED

AN aerial mail service between England and Australia is to be established by a new company, known as the "Aerial Services, Ltd.," which has been recently formed in New South Wales. One of the first steps of the company is to make a rough survey of the route to be followed, and this is to be done overland with Indian motorcycles and side cars. The expedition has already set out from Sydney, Australia, and the route to be followed is: Through New South Wales, portions of Queensland, across the Northern Territory, thence to Singapore, via Timor, through Java and Borneo, through the Malay Peninsula, across India and Persia to the Mediterranean Sea and thence to London. Landing places approximately 300 miles apart will be selected.



The party consists of Reginald Lloyd, leader; H. B. Manderson, secretary, a well known Melbourne journalist; J. Waldron, surveyor, who has been for seven years doing survey and exploration work for the Commonwealth Government in the Northern Territory, and is also undertaking the photographing and scientific work of the party; J. C. Marduel, a well known French aviator, who has seen active service in Egypt and Gallipoli, both with French and Australian armies, and was also instructor at the Aviation School, Point Cook, Victoria; W. J. Ousley, a motorcycle mechanic, and Kenneth Hunter, the second son of Mr. Percy Hunter, who is general assistant.

The party started on its mapping journey on January 31, making its night stop at Narrabri.

The route proposed to be followed from Narrabri is through Mungundi, Charleville, Longreach, Cloncurry and Bourketown. It is then understood that the party will proceed across the Northern Territory and to Singapore, via Timor, Java and Borneo.

In anticipation of the serious difficulties of travel by land a special outfit of firearms has been selected for each man to forestall trouble with the natives, and all kinds of medicines and emergency surgical apparatus forms part of the equipment. Motion pictures will be taken and many interesting pictures will no doubt be obtained in traversing those parts of the route which have never before been covered by explorers.

As soon as the route is mapped it is intended to cover the journey by aeroplane. Less difficulty is anticipated by this means of travel than by the trail-blazing motorcycle trip now under way.

One of the power nacelles of the British Dirigible R-34, in which is installed a 12-cylinder 275 H.P. "Maroi 4" direct drive Sunbeam Cotalen aircraft engine

THE TRANS-ATLANTIC FLIGHT

EVERY man and woman in the world who knows of Hawker and Grieve's gallant attempt to fly the Atlantic from Newfoundland to Ireland—and to what remote and inaccessible spot has news of their splendid effort not penetrated?—will give thanks that their daring has not cost them life, and will pray that they may be restored to their labors uninjured by their extraordinary adventure.

They had been given up as lost and an amount of money equal to the prize for which they contended had been awarded to their families; even their most hopeful friends had reluctantly abandoned hope for their safety when the news was flashed from midocean that they had been rescued from the sea.

They failed to complete the trip they undertook, it is true, but they displayed the fine sportsmanship that compels the admiration of all.

Harry G. Hawker and Commander Kenneth Mackenzie Grieve, the daring British aviators who flew from Newfoundland one week before were picked up in the middle of the ocean on May 25 after a flight of approximately 920 nautical miles, or 1,058 land miles.

They were rescued 750 nautical miles almost due west from the southwestern tip of Ireland, by the little Danish steamship Mary, bound from Norfolk, Va., to Denmark.

The exact position at which the men were found was announced by the Admiralty as latitude 50 degrees 20 minutes north and longitude 29 degrees 30 minutes west. The distance covered by Hawker and Grieve is roughly speaking 200 miles shorter than the record flight made by the American navy seaplane NC-4, which landed at Horta, Fayal Island, in the Azores, after a jump of 1,120 nautical miles, or 1,288 land miles.

The men were forced to drop into the sea because of the stopapge of the water circulation in the connecting pipe between the radiator and the pump.

Both men are in excellent condition.

The NC-4, the only flying boat of the naval transatlantic fleet remaining in commission, made the flight from Horta to Ponta Delgado on May 20, a distance of one hundred and fifty miles in one hour and forty-four minutes, or a speed of eighty-five miles an hour. Immediately after her arrival, mechanics began overhauling the motors for the next leg of the journey, the eight hundred-mile jump to Lisbon.

An effort was made on the following day, May 21, to resume the flight, but Lieutenant Commander Read reported engine trouble, which made it impossible to take off on that day. May 22 and 23 were extremely unfavorable, a high wind having sprung up.

The NC-3 has been dismantled for shipment to the United States, she having been damaged beyond repair in her long, rough trip after landing on the ocean's surface. Commander Tower's report follows:

"Arrived Ponta Delgada 17:50 G. M. T. (1:50 P. M. Washington time), May 19. Compelled to go above clouds at station eight on account of failure of lights on the pilot's instrument board and necessity of having heavenly bodies for reference. Last destroyer sighted No. 13. Came through the clouds at daybreak, but missed destroyer 14.

© Press Illustrating Service

Lieut-Commander Albert C. Read, commanding officer of the NC-4, the only contender remaining of the Naval trans-Atlantic fleet

"Believe thrown off course by high velocity of upper winds, but laid parallel course. Encountered heavy rain squalls 7:45 G. M. T. (3:45 A. M. Washington time), May 17, which continued until 13:30 G. M. T. (9:30 A. M. Washington time), when weather cleared and we decided to land to make observations, as we only had two hours' fuel left. Discovered heavy sea running too late to remain in air.

"Slightly damaged hull and seriously damaged forward engine struts on landing, which made it impossible to leave water.

"The New Arrivals" by Briggs in the New York "Tribune"

"Observations showed this position to be 47.45 north, 30:25 west. [Apparently this should be latitude 37 instead of 47 as given in the despatch.] Gale arose on evening of May 17, which was ridden out successfully until 9:00 G. M. T. (5 A. M. Washington time), May 19, when lost port wing pontoon.

"Seaplane suffered severely but succeeded in riding out gale, and by sailing a total distance of 205 miles made moorings at Ponta Delgada under own power at 17:50 G. M. T. (1:50 Washington time), May 19, having lost starboard pontoon just outside harbor. "Towers."

All hope that Hawker may have been picked up by a ship not carrying wirelessless appears to have been abandoned. Incoming steamers who were in the course of the Sopwith plane report that nothing was heard of the courageous Australian, nor was there any reply to repeated radio calls of Hawker's call letters. No trace whatever has been found of Hawker and Grieve since they disappeared into the sky off Signal Hill.

Undaunted by Hawker's disappearance and the damage in attempting to take off, Captain Frederick P. Raynham is dissembling his Martinsyde machine with a view to repairing it for the long flight. Captain Morgan's injuries are too serious to permit him to attempt the transatlantic flight. Raynham has cabled for another pilot and navigator.

Another contestant announced his entry for the transatlantic flight race in which success is rewarded by the "Daily Mail" prize of $50,000 and failure by almost certain death. The new challenger is Lieutenant Leth Jensen, a French pilot, who came here a few days ago to look over the ground. He has selected Mount Pearl plateau, from which Hawker winged his way, as his starting point. He left for France on May 23 to supervise the completion of his plane. He estimates that it will be two months before he can start. His course will be that of the other pilots entered.

Lord Northcliffe authorized the "Daily Mail" to pay Mrs. Hawker $50,000 for the benefit of herself and baby daughter, and to Commander Grieve's next of kin in the proportion which the airman and his navigator had agreed to share the prize money between them.

A large force of mechanics is working on the assembly of the Handley-Page at Harbor Grace, near St. John's. The Handley-Page biplane has a wingspread of 127 feet, the chord of which is the distance between the upper and lower planes 15 feet 8 inches, and a plane surface of 3,040 feet, with a lifting capacity of 9.08 pounds per square foot. She is fitted with four Rolls Royce Eagle engines, giving a total rated horsepower of 1,500.

In his non-stop flight of 1,361 miles on May 24, from Paris to Morocco, the first stage of the transatlantic flight to Brazil, Lieutenant Roget, the French aviator, broke the world's record of 1,350 miles set by the German aviator Lieutenant Boehm in 1914, who remained aloft 24 hours and 12 minutes.

THE NC-4 FLYING BOAT

THE Navy Department has just permitted to be published a description of the N.C. Flying Boats as they stood ready for trans-Atlantic flight. The issue of the AERIAL AGE for March 24th, 1919, contained outline drawings and a description of the original N.C.1, the first of the fleet.

The original N.C.1 was equipped with three tractor Liberty engines but the experience gained in designing the later machines was responsible for the addition of the fourth engine, a pusher, which put all the machines on equal footing.

The N.C. Type of flying boat represents strictly original American development. The design was initiated in the Fall of 1917 by Rear Admiral D. W. Taylor, chief constructor of the U. S. Navy. The big boats were designed for weight carrying and it was intended to use them in combating the submarine menace which had assumed alarming proportions in 1918. The N.C.1 was completed and given her trials in October, 1918. Since that time the N.C.2, N.C.3, and N.C.4 followed in quick succession.

Commander George Conrad Westervelt, U. S. N., has been in charge of the design and construction of the Naval Trans-Atlantic Flying Boats, as official representative of the Bureau of Construction and Repair.

During 1916 Commander Westervelt was Fleet Naval Constructor of the Atlantic Fleet. In January 1917 he was assigned to duty in Buffalo in charge of naval aircraft construction and inspection, his title later being made Superintendent of Aircraft. His headquarters were moved to New York in July, 1918, from where he supervised the inspection of all naval aircraft produced by Curtiss, Standard, Gallaudet, Aeromarine and Naval Aircraft Factories.

Fully loaded the machine weighs 28,000 lbs. and when empty (but including radiator water and fixed instruments and equipment) 15,874 lbs. The useful load available for crew, supplies and fuel is, therefore, 12,126 lbs. or over 43 per cent. This useful load may be put into fuel, freight, etc., in any proportion desired. For an endurance flight there would be food, water, signal lights, spare parts, and miscellaneous equipment (524 lbs.), oil (750 lbs.), and gasoline (9,650 lbs.). This should suffice for a flight of 1,400 sea miles. The radio outfit is of sufficient power to communicate with ships 200 miles away. The radio telephone would be used to talk to other planes in the formation or within 25 miles.

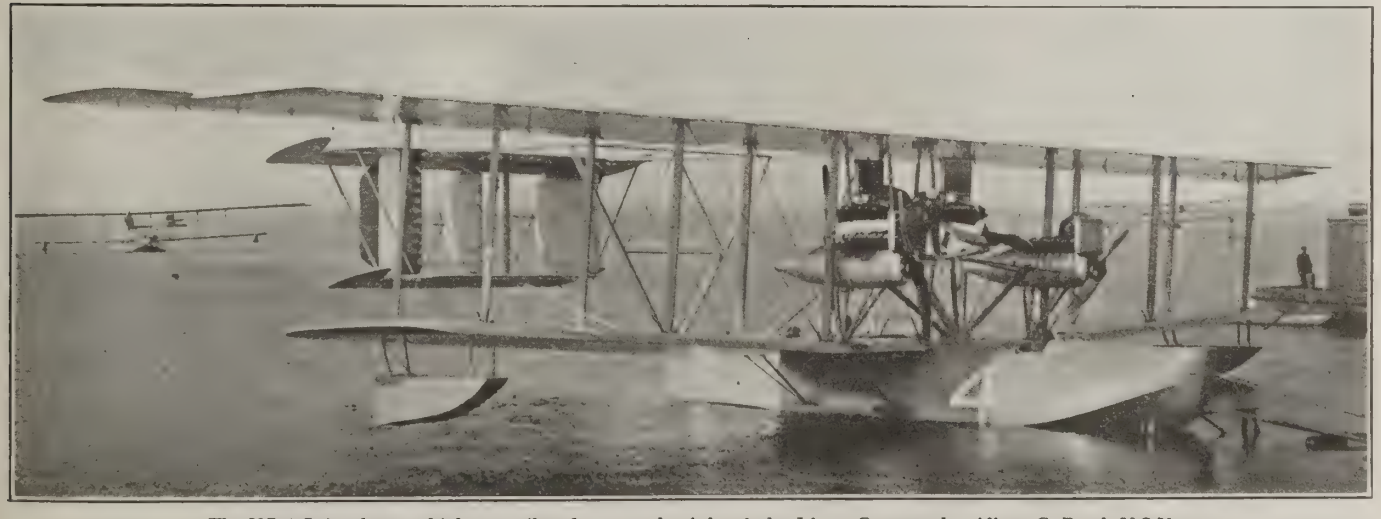
Speed range for 28,000 lbs.	74-58
Speed range for 24,000 lbs.	84-55

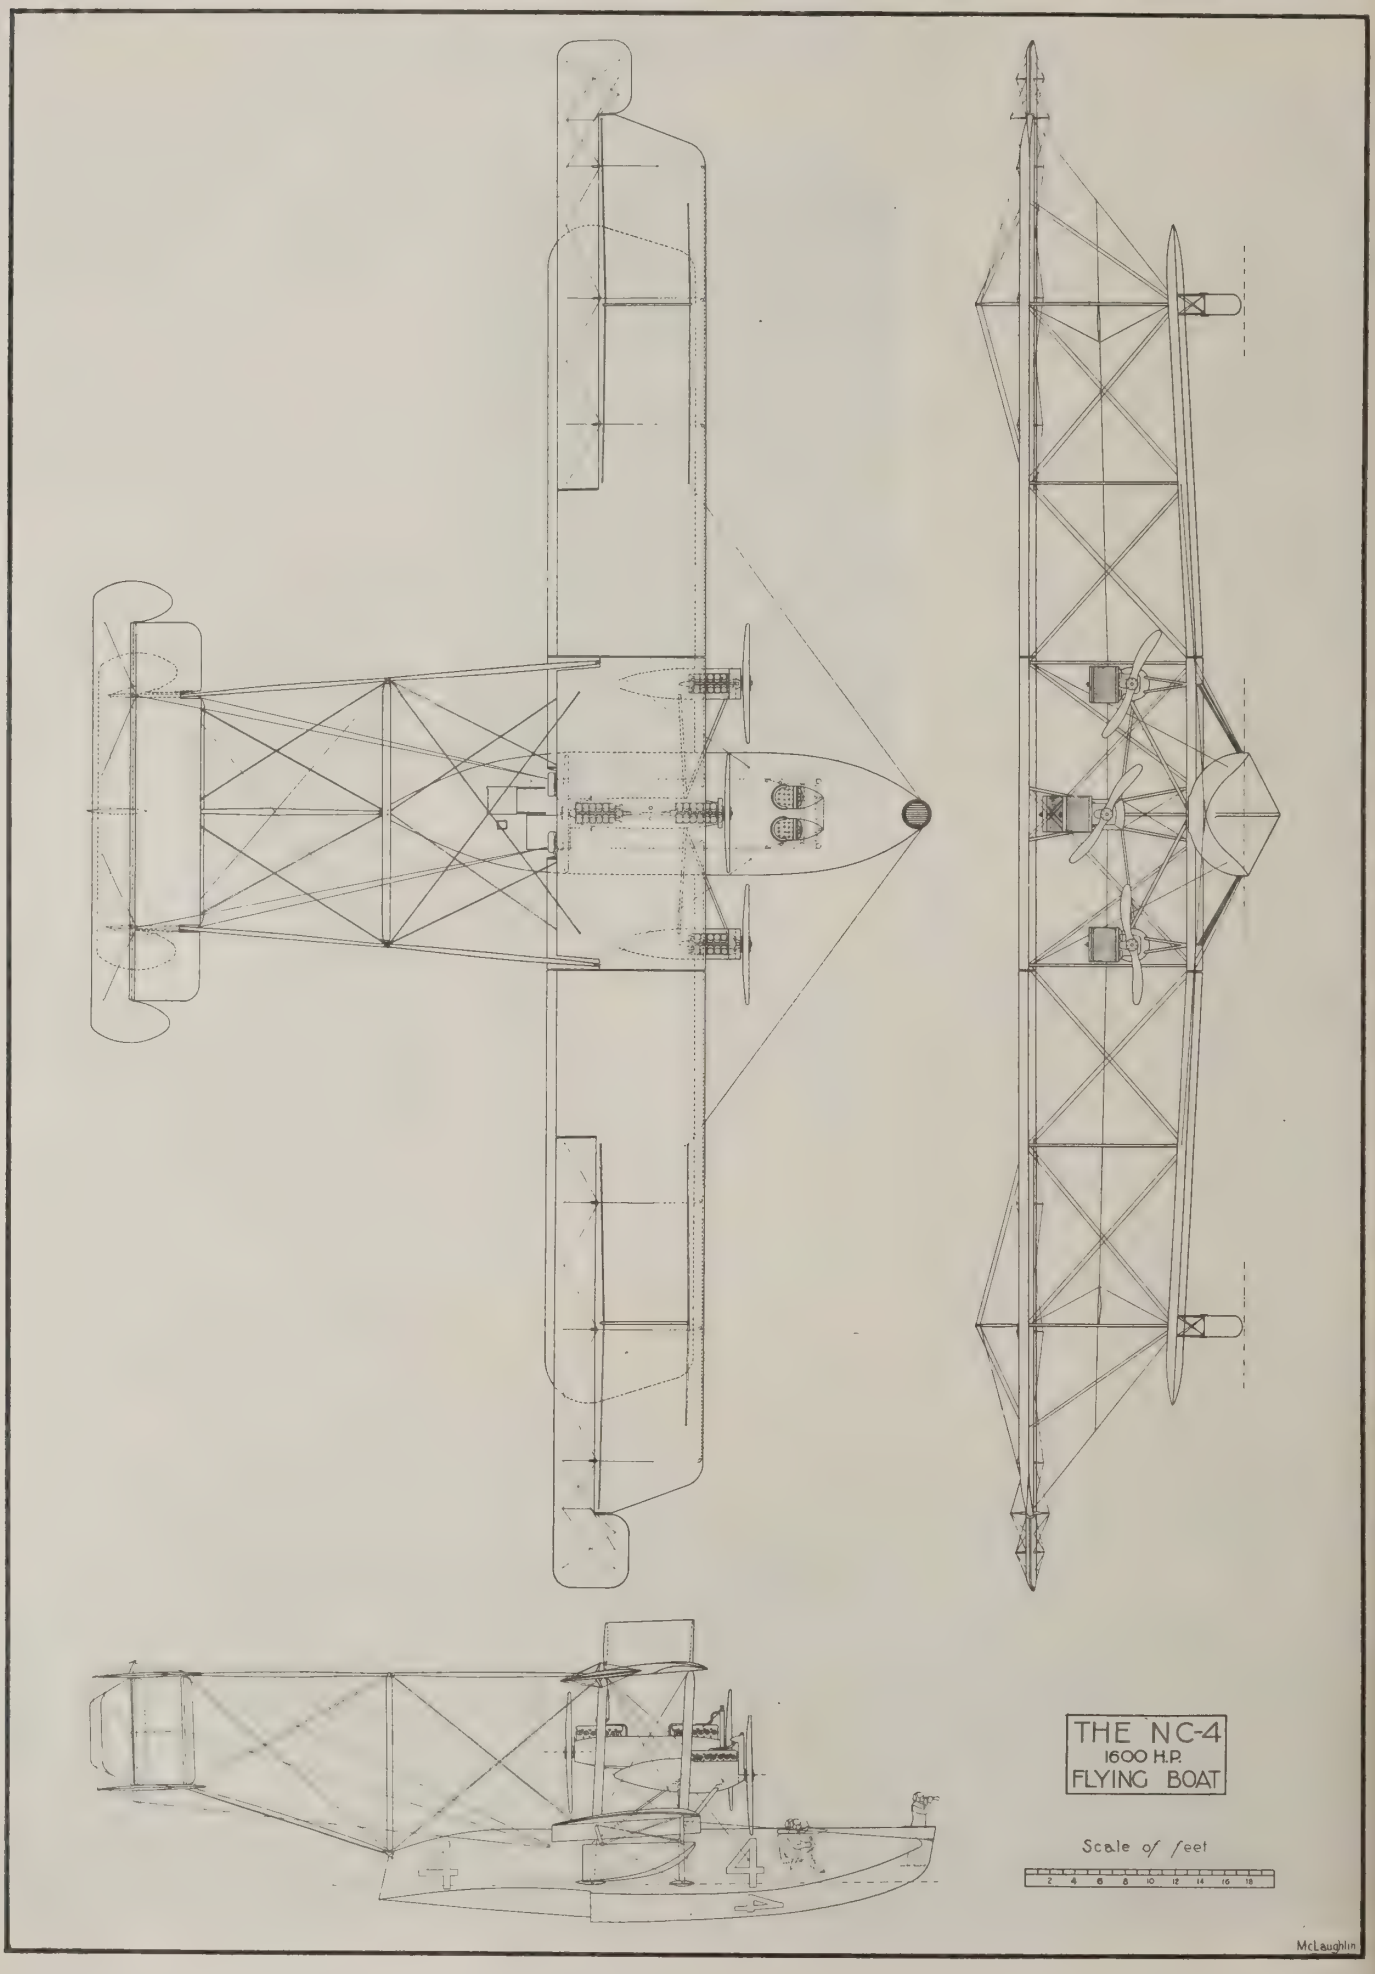
Main Planes

Considerable research and experiment was necessary to determine the best disposition of material to adopt for wings of this size. The R. A. F. 6 curve is used. The structural weight of the completed wings is only 1½ pounds per square foot, and they can carry a load of 11.7 pounds.



Wing spars are of spruce, box section. Ribs are made up of spruce cap strips tied by a system of vertical and diagonal strips of spruce.

Each rib weighs but 26 ounces. On test they were required to cary a proof sand load of 450 pounds for 24 hours without showing signs of weakness.



The leading edges of main planes are hinged to permit accessibility to the aileron control cables, which run concealed in the wing.

Interplane struts are of unusual construction. They are of box section spruce, faired off to a streamline shape by stiff fibre. To reduce any tendency of the struts to bow under load, the middle points are connected by steel cable.

The metal fittings where struts and wires are fastened to the wings presented a serious problem. The forces to be taken care of were so large that it was necessary to abandon the usual methods of the aeroplane builder and adopt those of the bridge designer. All forces acting at a joint pass through a common center. In this case, as in a pin bridge, the forces are all applied to a large hollow bolt at the center of the wing beam. In the design of the metal fittings to reduce the

The NC-4 flying boat, which was piloted across the Atlantic by Lieut. Commander Albert C. Read, U.S.N.

McLaughlin

amount of metal needed, it was decided to employ a special alloy steel of 150,000 lbs. per square inch tensile strength. To increase bearing areas, bolts and pins are made of large diameter but hollow.

The upper plane is in three sections; center section 25' 6½" in span. Lower plane in four sections; inner sections of the lower wing are built into hull. There is a clearance of ¼ inch between outer and inner plane sections.

Outer lower sections have a 3° dihedral; elsewhere plane sections are in flat span.

Ends of struts supporting middle engines are centered 50¾ inches apart. Between these struts the middle engines are located 6'10-3/16" above the center line of the front wing beam. The center line of the top front wing beam is located 6'7-15/16" above center line of nacelle.

The outer engine nacelles are centered 10'6-11/16" from the middle of the machine, and 4'5-1/16" above the top of the front wing beam.

The center engines are located 2'-0" higher than the outer engines.

The span of the upper plane not including the aileron extensions is 114'. Ailerons on the upper plane are 36' long. Cord 43". At the balanced portion the chord is 6'-1". Balanced portion extends 6' beyond the end of upper rear main wing beam. Ends of ailerons project 15' beyond lower plane.

Chord of main planes 12'. Forward main wing beam centered 16½" from leading edge; beams center 84" apart; trailing edge 43½" from center of rear beam.

Hull

The hull or boat proper is 44'-8¾" long by 10 feet beam. The bottom is a double plank Vee with a single step, somewhat similar in form to the standard Navy pontoon for smaller seaplanes. Five bulkheads divide the hull into six watertight compartments, with watertight doors in a wing passage for access. The forward compartment has a cockpit for the lookout and navigator. In the next compartment are seated side by side the principal pilot, or aviator, and his assistant. Next comes a compartment for the members of the crew off watch to rest or sleep. After this are two compartments containing the gasoline tanks (where a mechanician is in attendance) and finally a space for the radio man and his apparatus. The minimum crew consists of five men, but normally a relief crew could be carried in addition.

The hull is designed to have an easy flaring bow so that it can be driven through a seaway to get up the speed necessary to take the air and a strong Vee bottom to cushion the shock of landing on the water.

The combination of great strength to stand rough water with the light weight required was a delicate compromise, and it is believed that a remarkable result has been obtained in this design. The bare hull, as completed by the yacht builder and ready for installation of equipment, weighs only 2,800 lbs., yet the displacement is 28,000 lbs., or one-tenth of a pound of boat per pound of displacement. This lightness of construction was attained by a careful selection and distribution of materials.

The keel is of Sitka spruce, as is the planking. Longitudinal strength is given by two girders of spruce braced with steel wire. To insure water-tightness and yet keep the planking thin, there is a layer of muslin set in marine glue between the two piles of planking.

The Hull is 44'-8¾" in overall length. Step is located 27'-8¾" from the bow. The stern rises in a straight line from the step in a total height of 41½". The hull has a maximum depth of 7'-5⅞", and a maximum width of 10'. The leading edge of upper main plane is located 18'2" from the bow.

Tail Group

The biplane tail is carried on three hollow spruce outriggers. Front beam of upper horizontal stabilizer is 30'-11¼" from trailing edge of main plane. Gap between tail planes, 9'-3". The single lower outrigger from the hull to the lower stabilizer is attached to the stabilizer at a point 10'-11" above the lowest point of the hull.

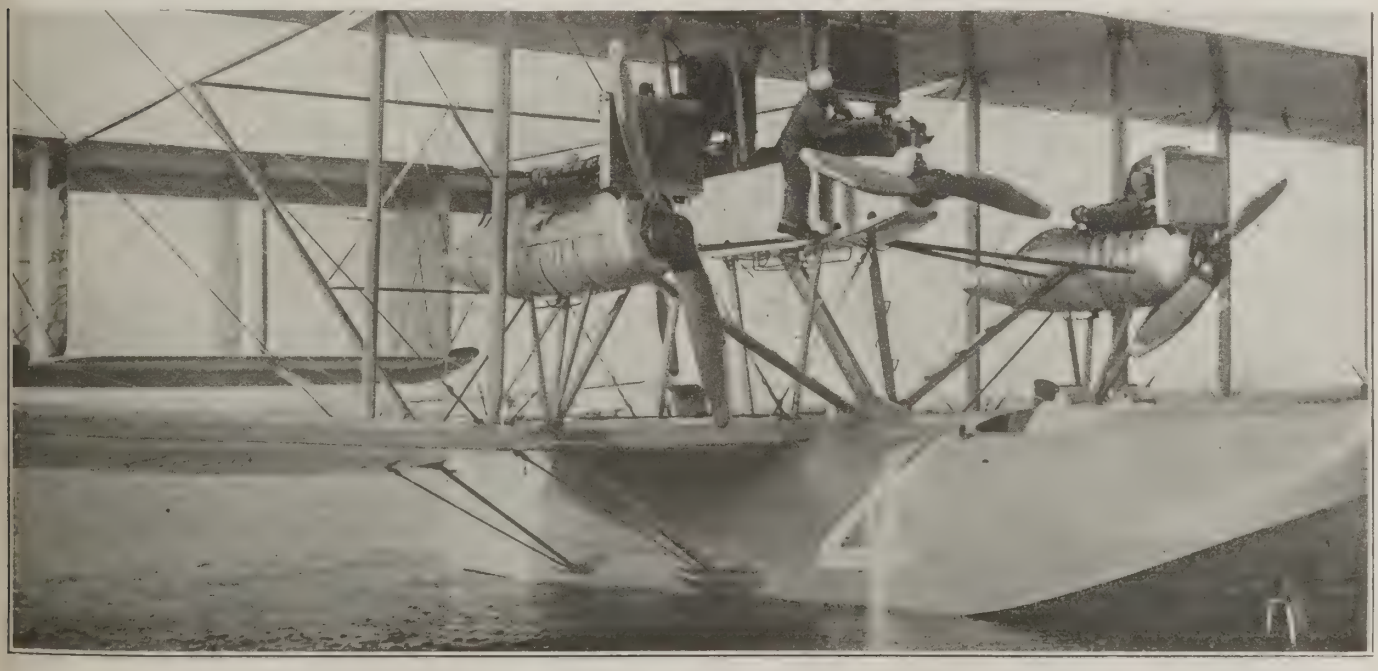
Span of upper elevator, 37'-11". The lower stabilizer is 32' in span. Ends of upper elevator project 5'-11½" beyond the lower stabilizer. The balanced portion of the elevators is 6'-5" in width.

The upper stabilizer is 31' in span. Lower stabilizer 19' in span. Chord of both stabilizers 5'6".

Vertical fins between stabilizer planes are located at ends of lower stabilizer. From these fins, rudders are hinged, interconnected to balanced rudder situated at the middle of tail plane.

The tail planes have a positive incidence angle of 2°.

Controls



The steering and control in the air are arranged in principle exactly as in a small aeroplane, but it was not an easy problem to arrange that this 14-ton boat could be handled with ease by one man. To obtain easy operation, each control surface was balanced in accordance with experiments made in a wind tunnel on a scale model. The operating cables were run through ball bearing pulleys, and all avoidable friction eliminated. Finally, the entire craft was so balanced that the center of gravity of all weights came at the resultant center of lift of all lifting surfaces and at the tail surfaces so adjusted that the machine would be inherently stable in flight. As a result, the boat will fly herself and will continue on her course without the constant attention of the pilot. When he wishes to change course, however, a slight movement of the controls is sufficient to swing the boat promptly. There is provision, however, for an assistant to the pilot to relieve him in rough air if he becomes fatigued or wishes to leave his post to move about the boat.

Engines

The four Liberty engines which drive the boat are mounted between the wings. At 400 brake horsepower per engine, the maximum power is 1,600 H.P., or with the full load of 28,000 pounds, 17.5 pounds carried per H.P. One engine is mounted with a tractor propeller on each side of the center line, and on the center line the two remaining engines are mounted in tandem, or one behind the other. The front engine has a tractor propeller and the rear engine a pusher propeller. This arrangement of engines is novel and has the advantage of concentrating weights near the center of the boat so that it can be manoeuvred more easily in the air.

A feature that is new in this boat is the use of welded aluminum tanks for gasoline. There are nine 200-gallon tanks made of sheet aluminum with welded seams. Each tank weighs but 70 lbs., or .35 lb. per gallon of contents, about one-half the weight of the usual sheet steel or copper tank.

The face of the radiator for outer engines is 15'-2⅞" from the bow. The face of the radiator for the forward middle engine is 19" back of the face of other radiators. The center line of central nacelle is 6'-5-1/16" above the deck of the hull. Above outer interplane strut the center line of front wing beam is located 13" above the deck of the hull.

CAMERAS FOR AERIAL PHOTOGRAPHY

By EDGAR H. FELIX, I. R. E.

Formerly Radio Engineer, Signal Corps

NOW that we can turn to the arts of peace those instruments developed for the prosecution of war, it is interesting to inquire into the field of utility of that subject of extensive experiment—the aeroplane camera.

The exacting conditions of military service have resulted in the development of aeroplane cameras of such marvelous sensitiveness, yet of the utmost simplicity of operation, that astounding results were obtained. The public, however, is gen-

The B-1 Camera is very simple and rapid in operation

erally familiar with the service which the aeroplane camera rendered. Photographic maps or "mosaics" have appeared in numerous newspapers and periodicals, and the work of the aerial observer has been frequently described.

The extreme sensitiveness of the aero camera, is not, however, generally appreciated. The largest size of camera in use at the front could make a picture of the ground beneath from an altitude of 15,000 feet, which, when enlarged, revealed the foot-prints of men in the sand. And to obtain this extremely detailed picture from such an altitude an exposure of only one five hundredths of a second was required.

Upon reaching the ground, a staff of trained photographers, equipped with highly developed apparatus, were able to deliver within fifteen minutes, a finished photograph for use of the staff.

It was found for the more accurate work that plates were more suitable than films. Plates are bulkier and heavier, but for chemical reasons, better results are obtainable. For instance, a plate was developed which was capable of photographing the ground below through haze, fog, smoke and light cloud, through which the eye could not penetrate.

The perfection of the pan-chromatic plate and the ray filter has resulted in photographs possessing most remarkable graduation of color value. It is possible, for instance, to distinguish the several species of evergreen trees appearing on a negative taken from an altitude of 15,000 feet.

Automatic cameras, which take a photograph at regular intervals, adjusted according to the speed and altitude of the plane, have made the production of photographic maps a matter of precision and ease. For instance, at the School of Aerial Photography, army students made a map of the city of Rochester, involving the use of six hundred photographs, in a space of two and a half hours.

Photographic map-making readily suggests itself to peace use. However, instead of taking pictures at altitudes of 10,000 and 15,000 feet, owing to anti-aircraft barrage and under constant danger from enemy attack, the peace-time aerial photographer can take his pictures from a low altitude—1,500 feet for instance—and secure as a result a more detailed map.

The aero-map, if I may use that term, must, however, possess advantages over ground photos and maps, to make them a commercial proposition. There are cases where, because of heavy vegetation, marsh, or other difficulties of terrain, that ordinary methods of ground surveying are hazardous and extremely expensive. Herein lies an extensive field of utility for the aerial camera.

As a practical illustration, it has been suggested to one enterprising lumber man whose holdings extend over hundreds of miles of virgin forests, some of which has never been explored, that aeroplane photos be taken at intervals of a mile or two, in order that an accurate estimate of the amount and location of each species of lumber is available on his tracts. Such photos will make possible the filling of the needs of the market in the shortest possible space of time.

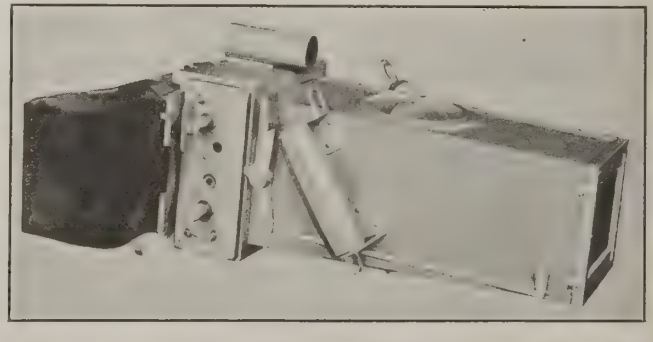
In the field of exploration, the advantages and utility of the aeroplane and aero-camera require no exposition. The aeroplane affords a rapid and safe means of transportation, and the aerial camera an accurate and graphic means of recording observations.

Another field of utility will be the photographing of real estate for advertising purposes. A bird's eye view not only permits the presentation of a large tract on one photograph, but forms a most attractive and pleasing advertisement.

Chambers of commerce will undoubtedly utilize the aero-camera for securing photographs of their city, to show the railroad lines, harbor facilities, good arrangement of streets for hauling manufactured products, residential sections for workmen's homes, factory districts, groups of large business buildings and other purposes.

Photographs of the same district taken at intervals of a few years or months can illustrate more eloquently than any array of graphs or statistics the growth of a city or district..

Progress in the construction of engineering projects, such as buildings, bridges, canals and railways, as well as comparative merits of various types of city planning, can be efficiently recorded by the aero-camera.



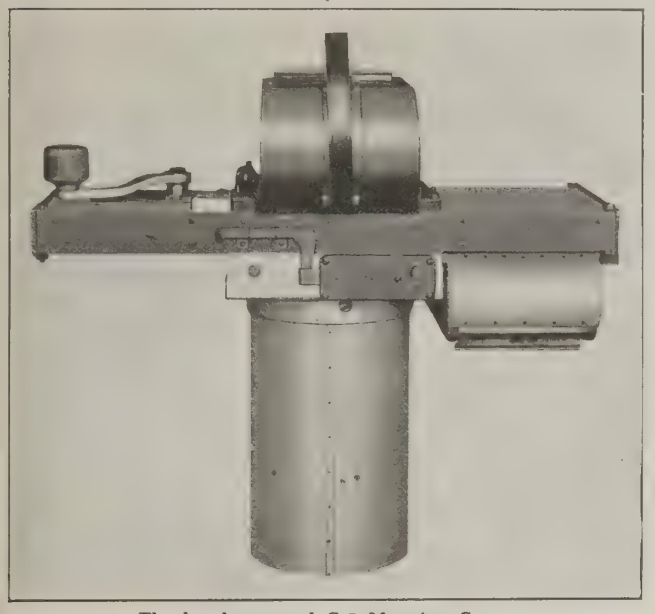
Another field for the aero-photo, which has already had limited use, is in the securing of news pictures. It is only a question of time before the news film companies employ this means of securing photos and films for the screen. The advantages of this method of presentation are obvious. For instance, instead of having a few feet of films taken along the route at the start and finish of the intercollegiate boat races, it is likely that the public will be able this year to see all the exciting moments of the race. The film taken from above will show perfectly the gains and losses of the contenders—even better than the spectator, whose view is limited to one point—will be able to obtain.

The Eastman Kodak Company has produced a large proportion of the aero cameras used in the war by the American forces. Several types are illustrated, and serve to show the high state of development to which they have been brought.

The simplest of these cameras is the type known as A-1. Excellent control over the camera is provided by the two side grips and the position of the thumb lever shutter release. Three movements only are required in making exposures: set the shutter, press the thumb lever release, shift exposed plate.

The body of the camera is made of cast aluminum, and the cone of sheet aluminum. Two lugs for attaching shoulder straps are provided. The shutter permits of adjustment to speeds of 1/120 to 1/435 of a second. A 10" lens having a fixed aperture of f.4.5 is especially designed for this camera. A running thread and set screw permits accurate adjustment at infinity focus.

As a protection against exposure of the lens to fog, mist, or dirt, preventing impairment of the photographic record or against fogging of plate or film, a safety shutter is provided, which is released just before the exposure is made. A direct vision tubular finder, having intersecting vertical and horizontal wires, provides for proper sighting of the camera.



The A-1 Camera is the smallest and lightest type of camera which had extensive use in the war

Either twelve 4 x 5 graflex plates or Eastman cut film may be used on this camera.

The B-1 model is very similar to the A-1. The chief difference in construction lies in the mechanism for rapidly changing the exposed film, resetting the focal plane shutter, and the advantage of daylight loading with cartridge film.

The operation of this model is very simple and exceptionally rapid. The camera is sighted, and a slight pressure upon the

The hand-operated C-2 Mapping Camera

thumb lever release opens the safety shutter, exposing the lens, and makes the exposure. One short, quick turn of a lever advances the film and resets the shutter. This operation can be repeated until 12 exposures have been made. The film is then rewound on the original spool, removed and replaced. The camera weighs ten pounds.

The Model C-2 camera is designed for photographic mapping, to be mounted on a suitable vibration absorbing device, over an aperture in the floor of the plane.

Two metal magazines having phosphor bronze dark slides are provided. These magazines have a capacity for 24 plates in metal septums. The planes in the upper magazine are fed by gravity to the recording plane. The exposure is made by a slight pull of the forefinger upon the shutter release lever. A quick quarter turn of the rotary lever feeds the exposed plate into the lower receiving magazine, closes the recording aperture and resets the focal plane shutter. The rotary feed lever is then returned to its original position, bringing the operator's hand directly over the shutter release lever, ready for the next exposure. The same type of lens and shutter is supplied with this camera as with the A-1, except that its focal length is 8½ inches. The total weight of the camera, loaded with two magazines, is 21 pounds.

A highly perfected automatic mapping camera, known as type K-1, is best suited to extensive mapping operations. It is entirely automatic in its action. The only operation required is starting the camera. One or more exposures, within the limitation of the roll of film, may be made at will by means of a lever controlling the wind motor driving mechanism. The roll film used is 9½ inches wide and 75 feet long, sufficient for 100 exposures. The film is held accurately in the recording plane by constant vacuum suction produced by the Venturi tube, which forms part of the motor mechanism, thereby overcoming all vibration.

The wind motor operating the camera is mounted outside the fuselage, and is connected with the camera by means of a flexible shaft passed through the side of the plane. Control for regulating the time between exposures in correct ratio to the speed and altitude of the plane is conveniently located inside the plane. After each exposure a safety curtain is automatically drawn across the recording plane, thus protecting the film while the shutter is being reset and unexposed film advanced into position.

The shutter permits a variation in exposures from 1/90 to 1/310 of a second. The lens has a focal length of 20 inches and an aperture f.6. The total weight of the camera loaded, with 100 exposure film complete, is 44 pounds.

Although the Eastman Company has not released these cameras for the general public, because they are still on production on Government orders, it is probable that the types described will soon be made available for private use.

Circulation and Piling in the Dry Kiln

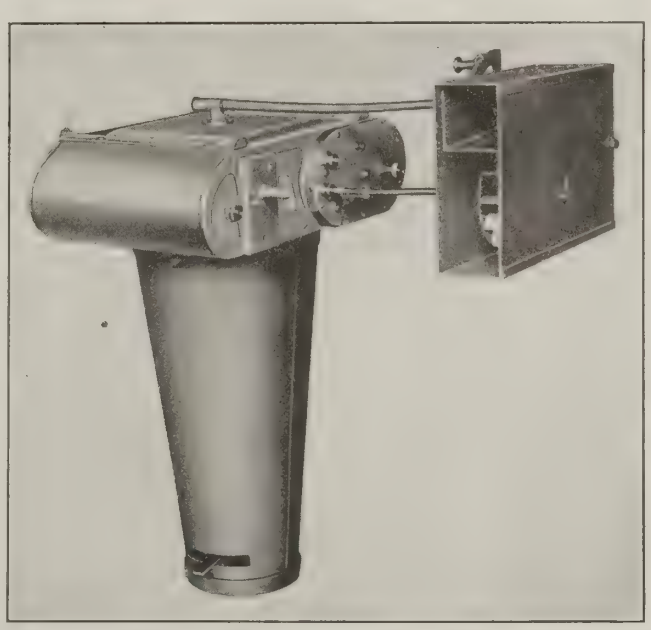
A GOOD dry kiln when empty may be a poor dry kiln when loaded with lumber, simply because the wrong method of piling is used. Circulation of air is necessary to distribute the heat and humidity uniformly to all parts of the kiln and to all parts of the lumber pile. In a kiln of good design the circulation is carefully provided for, but obstructions caused by improper piling may defeat the designer's plan.

There are few more effective ways of baffling circulation than by piling into the kiln a quantity of lumber across the path which it was intended the air should follow. If this is done, the circulation becomes sluggish and uneven, permitting the formation of cool pockets in which lumber does not dry and hot pockets in which lumber is ruined.

Air moves differently in different types of kilns, therefore, the proper method of piling the lumber will vary with the kind of kiln used. To run lumber into the dry kiln endwise, or crosswise, or edgewise, without regard to whether the stickers are to be perpendicular or parallel to the direction of circulation is a blind effort and not at all conducive to efficiency or satisfaction.

This point was brought very forcibly to the attention of the Forest Products Laboratory some years ago, when a problem in the operation of a dry kiln of new construction and good design was presented by a large commercial concern. Although the new kiln was far superior to the old one when empty of lumber, in points of design and control apparatus, it dried lumber more slowly and less evenly than the old kiln.

The trouble was that the same system of piling was used in both cases, although the direction of circulation had been changed in the new kiln. The system of circulation in the new kiln was much preferable to that in the old, but the old method of piling, which was intended only for the old kiln, threw the balance the other way.



This experience led to careful tests, the results of which have very general and broad application in commercial practice. In a kiln having vertical-lateral circulation, such as is usually characteristic of condenser kilns and of many ventilated compartment kilns, lumber was piled both endwise and crosswise. A curtain was dropped from the ceiling between the two piles in such a way that each pile dried according to the same temperature and humidity. Temperature and humidity readings were taken daily, at different parts of each pile. On the eighth day, for example, the readings were as follows:

Cross piled lumber		*End piled lumber*	
Center of the pile	110° F.	Center of the pile	142° F.
Underneath	168° F.	Underneath	152° F.
Above	146° F.	Above	146° F.

The difference in temperature between the center and bottom of the first pile (cross piled) was 58 degrees, while in the second pile (end piled) the difference was only 10 degrees.

Naturally such differences in temperature at various parts of the piles had a decided effect on the rate and uniformity of drying. The end piled stock dried in 10 days from a moisture content of 30 per cent to a maximum moisture content of 6 per cent. The stock piled crosswise took 13 days to dry from 30 per cent down to 12 per cent.

The lesson is obvious. Lumber should be piled to suit the circulation in the kiln. [Technical Notes of the Forest Products Laboratory, U. S. Forest Service.]

The K-1 Automatic Camera merely requires setting, the mechanism does the rest

THE SUNBEAM AERO ENGINE

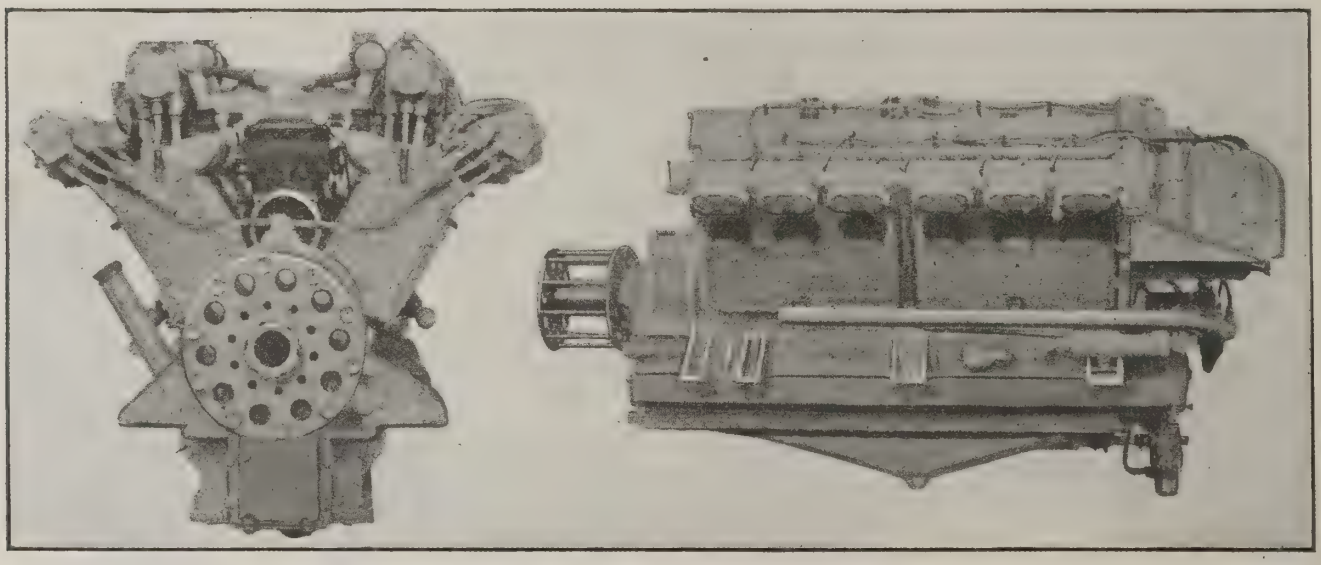
IN our last issue we illustrated the "Arab," "Cossack" and "Manitou" Sunbeam aero engines, and this week we take pleasure in presenting some general characteristics of these power plants.

"ARAB" I

8 cylinders.
90° Vee.
Three valves per cylinder.
120 mm. bore.
130 mm. stroke.
12,260 cubic centimetres volume.
Articulating connecting rod system.
Normal revolutions, 2,000 per minute.
Approximate weight per horse-power, 2·5 lb.
Maximum horse-power obtained at 2,000 crankshaft revolutions per minute, 235.
Average petrol consumption, 0·54 pint per horse-power per hour.
Claudel Hobson carburetor, type H.C.7, set in centre of Vee formed by cylinder blocks.
Variable ignition by two 8-cylinder magnetos.
Lubricant consumption, average 6·5 pints per hour of castor oil. Normal oil pressure to main engine details at full power, 45 lb. per square inch.

This engine has also been made with direct drive instead of with reduction gear. A number of these engines have been fitted with hand starters.

"MANITOU"



12 cylinders.
60° Vee.
Reduction gear teeth ratio, 28 to 44.
Four valves per cylinder.
110 mm. bore.
135 mm. stroke master road side.
142 mm. stroke link rod side.
15,794 cubic centimetres volume.
Articulating connecting rod system.
314 brake horse-power.
Nominal revolutions, 2,000 per minute.
Approximate weight per horse-power, 2·5 lb.
Average petrol consumption, 0·54 pints per horse-power per hour.
Claudel Hobson carburetor, type H.C.7, set in centre of Vee formed by cylinder blocks.
Variable ignition by two 12-cylinder magnetos.
Lubricant consumption, average 8 pints per hour of castor oil. Normal oil pressure to main engine details at full power, 40 lb. per square inch.

This engine is designed to take an electric starting motor, as well as being fitted with a hand starter.

"MAORI IV"

The "Maori" IV Sunbeam-Coatalen water-cooled aircraft engine has been specially designed for airship work. It has:
12 cylinders.
60° Vee.
Four valves per cylinder.
100 mm. bore.
135 mm. stroke.
12,720 cubic centimetres volume.
Articulating connecting rod system.
275 brake horse-power.
Normal revolutions per minute, 2,000.
Approximate weight, 3·3 per horse-power.
Average petrol consumption, 0·54 pint per horse-power per hour.
Claudel Hobson carburetors, type B.Z.38, set outside.
Variable ignition by two 12-cylinder magnetos.
Lubricant consumption, average 6·5 pints per hour castor oil. Normal oil pressure to main engine details at full power, 45 lb. per square inch.
Fitted with hand starter and electric motor.

The following special fittings are included:—Water-cooled exhaust pipe, automatic governor to prevent over-running, flywheel in place of reduction gear, and extra large water pump to ensure efficient circulation.

Book Review

A TEXT-BOOK OF AERONAUTICS. By Herman Shaw, B.Sc., A.R.C.S., A.F.Ae.S.

A well-arranged text-book on aeronautics, which sets forth in clear and concise language all that the student needs to know in the preliminary stages of his work, and leads him in an interesting manner into more advanced studies, giving him sufficient details to master the difficult problems which present themselves in practice. A thorough study of the book will enable the student to excel in his profession, and will reduce the hazards to a minimum, in the opinion of professional experts.

The author has in this volume recast his lectures to officers of the English R.N.A.S. and R.A.F., given during the period of the war, with additions and many illustrations calculated to add to its value as a text-book of aeronautics. As an instructor of that English air force which reached the highest pitch of excellence during the war, the author has proved the value and efficiency of his methods.

The chapter headings given below will give an outline of the scope of the book. The illustrations are clear and easy of comprehension, and accompany and elucidate the text throughout.

Chapters: I, Some Mechanical Considerations; II, Air Flow; III, Wing Characteristics; IV, Streamline Flow; V, Dynamics of the Aeroplane; VI, Equilibrium of the Aeroplane; VII, Stability; IX, Construction; X, Aero Engines; XI, Air Screws; XII, The Seaplane; XIII, Instruments and Their Use; XIV, Types of Machines; XV, Design of an Aeroplane; XVI, Rigging, Testing and Maintenance of an Aeroplane; XVII, Balloons and Airships; XVIII, Aerial Navigation; XIX, Meteorology; XX, Bomb-Dropping; XXI, Wireless Telegraphy in Aircraft; XXII, Aerial Photography; Index.

This book may be purchased from the Aeronautic Library, 299 Madison Avenue, New York, at a price of $3.75 post paid.

THOMAS-MORSE TYPE S-5 SEAPLANE

THE Navy Department has been using a number of the S-5 Seaplanes for training purposes at the Navy Air Station, Miami, Florida. This plane is really an S-4 C Scout fitted with twin floats. It is the only kind of this type used by the Navy.

The power plant consists of a 100 H.P. Monosoupape Gnome engine.

The Thomas-Morse S-5 Seaplane

General Dimensions

Length	22′ 9″
Spread	26′ 6″
Height	9′ 7″

Weights

	(*pounds*)
Total weight loaded	1500
Loading per sq.ft. of lifting surface	6.25
Weight of machine loaded per h.p.	14.3

Power Plant

Type of engine Gnome (air cooled rotary)	100 H.P.
Engine R.P.M.	1250
Fuel capacity	30 gallons
Fuel duration at full power	3 hours
Oil capacity	6.5 gallons
Oil duration at full power	3½ hours
Propeller type	2 bladed
Propeller diameter	8′ 0″
Propeller R.P.M.	1250

Chassis

Type	Twin pontoons and tail float

Areas

	(*square feet*)
Area lifting surface (including ailerons)	240
Ailerons (two)	30
Elevators	22
Rudder	8.5
Horizontal stabilizer	16.8
Vertical stabilizer	3.5

Performance

High speed	95 M.P.H.
Low speed	50 M.P.H.
Climb in first ten minutes	5200′

THE THOMAS-MORSE S-4 E SINGLE SEATER

THE S-4 E is a modification of the S-4 C Type, brought out to meet the requirements of those desiring a faster machine using the same engine, an 80 H.P. Le Rhone. Besides reducing the wing area, the weight has been reduced by approximately two hundred pounds.

Tapering wings have been fitted with both main wing beams well forward, leaving a slightly flexible feather edge. Remarkable manoeuvering qualities are inherent with this design; the slightest effort is required by the pilot in performing all acrobatics.

General Dimensions

Span	22′ 6″
Length	19′ 4″
Height	7′

Weights

Total weight loaded	1,150 lbs.
Area lifting surface (including ailerons)	145 sq. ft.
Loading per sq. ft. of lifting surface	8 lbs.
Required horse power	90
Weight of machine loaded per horse power	12.8

Power Plant

Type of engine	Le Rhone (air cooled rotary) 80 H. P.
Engine R. P. M.	1,250
Fuel capacity	20 gal.
Fuel duration at full power	2½ hours
Oil capacity	4 gal.
Oil duration at full power	3 hours
Propeller type	2 bladed
Propeller diameter	7′ 6″
Propeller R.P.M.	1,250

Chassis

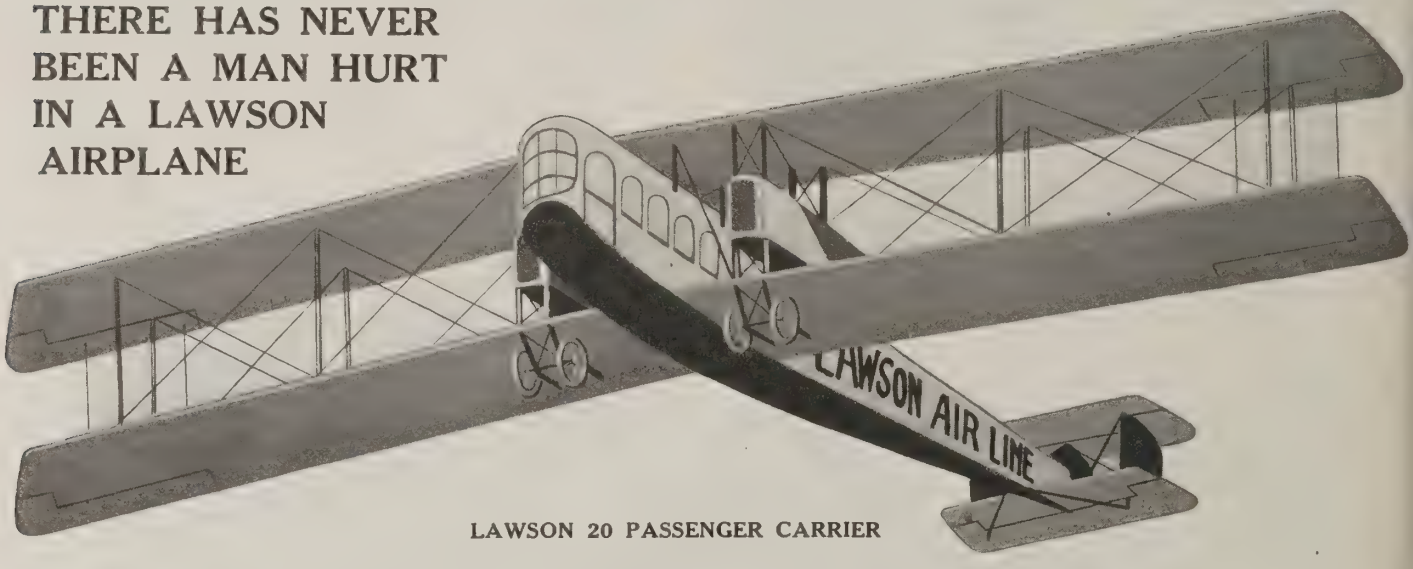
Type	"vee"
Wheels	2 (tread 5 ft.)
Tires	26″ × 3″

Areas of Control Surfaces (*Square Feet*)

Ailerons	16.4
Elevators	16.8
Rudder	7.3
Horizontal stabilizer	11.2
Vertical stabilizer	3.8

Performance

High speed	112 m.p.h.
Low speed	55 m.p.h.
Climb in first 10 minutes	8,500 ft.



The Thomas-Morse S-4 E Single Seater Advanced Training Scout, which makes a speed of 112 m.p.h. with an 80 H.P. Le Rhone engine

Lawson

Creator of Improved Aircraft

THERE HAS NEVER BEEN A MAN HURT IN A LAWSON AIRPLANE

LAWSON 20 PASSENGER CARRIER

QUICK DELIVERIES CAN BE MADE ON ANY OF THE FOLLOWING NEW TYPES

LAWSON TWO ENGINE 20 PASSENGER CARRIER
LAWSON THREE ENGINE 32 PASSENGER CARRIER
LAWSON TWO ENGINE MAIL CAR—CARRIES 3000 Lb. MAIL
LAWSON THREE ENGINE MAIL CAR—CARRIES 4000 Lb. MAIL
LAWSON STEEL BATTLER—CARRIES 8 MACHINE GUNS

All Lawson aircraft, whether commercial, military or sporting types, are planned, designed and built under the direction of Alfred W. Lawson, the well-known aeronautical expert, who has had 12 years of all round practical experience in aircraft work.

Lawson Air Line Transportation Company

MILWAUKEE, WIS.

BUILDER OF BIG AIRCRAFT

Was First to Advocate Them

ALFRED W. LAWSON, PRESIDENT OF THE LAWSON AIRLINE COMPANY, PLANNED BIG SHIPS OF THE AIR MANY YEARS AGO

NOW that the large aircraft has been so successfully demonstrated it is interesting to note that Alfred W. Lawson, President of the Lawson Air Line Company, was one of the first of the Aircraft manufacturers of the world to advocate their construction and utility.

As far back as 1908, Mr. Lawson as editor of the Magazine "Fly," which he established, frequently called the attention of his readers to the Big Passenger carrying ships of the air that would eventually come, and subsequently, during the years 1910-1911 and 1912, he, as editor of the Magazine "Aircraft," literally filled its pages with his forecasts of big ships in the air.

In 1911 Mr. Lawson as General Manager of the Farman Company of America, endeavored to have that Company build big ships, but at that time capital could not be induced to take such an advanced step.

In 1913 Alfred W. Lawson entered into an agreement with Johann Schuette of the Schuette-Lanz Airship Company of Germany, to establish a passenger carrying air line between New York and Washington. Arrangements were under way for this project when Mr. Schuette notified Mr. Lawson that the Kaiser had forbidden the plans of the Schuette-Lanz Airship going out of Germany.

Mr. Lawson has spent all of his time during the last twelve years in helping to build up the Aircraft industry in America and he has thus gained practical experience from every angle.

The big passenger and mail carrying ships that are now being built under Mr. Lawson's direction in Milwaukee, Wisconsin, are therefore but the outcome of plans he had thought out years ago and which he strived to interest capital to build, then, without success.

During the past three years Mr. Lawson was General Manager of the Lawson Aircraft Corporation, who were principally occupied in building military airplanes. Many new and original types of military machines were designed and built under Mr. Lawson's direction during the war.

The M.T. 1 for primary training; the M.T. 2 for advanced training, the M.T. 3 for Reconnaissance work and an all steel machine—the Lawson Battler—for trench, infantry and cavalry fighting were right up to the minute in their performances. (The Steel Battler was not finished at the time hostilities ceased.)

One thing in particular that Mr. Lawson takes great pride in, and that is that there has never been a man hurt in a Lawson airplane. He is a stickler for safety even at the expense of performance. However, he has up to date invariably gotten the performance as well as the extra safety put into his machines.

More than a year ago, when it was found impossible for steam ships to transport all of the airplanes across the Atlantic that America was preparing to build, Alfred W. Lawson invented the "Trans-Oceanic Float System," whereby a thousand airplanes a day could be sent streaming across the ocean under their own power.

According to this system a number of steamships devoid of their superstructure and known as "Floats" were to be stationed at intervals of fifty miles apart across the Atlantic to act as guide posts and signal and landing stations for all types of airplanes, from whence fuel and aid could be obtained and repairs made when necessary. Land airplanes were to alight upon the decks of these steamships or floats, while flying boats or hydro-airplanes were to alight upon the water alongside of them.

The plans of this system were given to both the United States Navy and Army officials by Mr. Lawson in June, 1918, and shortly afterward the same plans were given to the British Navy.

Mr. Lawson's system made crossing the Atlantic Ocean by airplane a very simple process, a practical everyday feat that could be accomplished by any number of ordinary aviators on any sort of airplanes.

The transatlantic flight by a Navy flying boat recently was made according to the principles of Mr. Lawson's Floating System.

The Navy stationed steamships across the ocean at intervals of fifty miles apart, as indicated in Mr. Lawson's plans, to act as guide posts, signal stations and for fuel and repair ships in case of need.

Events proved conclusively that without these floating stations the Navy flight could not have been made.

The failures of F. P. Raynham and Harry G. Hawker in their attempts to make non-stop flights across the Atlantic prove the futility or at least the uselessness of that system for some time to come.

Recently published photographs show that the British Navy have already successfully tried out and adopted steamship floats for land airplanes to alight upon at sea.

Had the British Navy stretched these steamship floats across the Atlantic at intervals of fifty miles as the United States Navy did with their warships, then Harry Hawker, F. P. Raynham or any other aviator could have flown across the ocean with ease and certainty, and it would not have been necessary to leave their wheels behind or break down from overloading with fuel.

The British Navy would then have proved Mr. Lawson's system for land machines as the United States Navy proved it for flying boats.

THE LAWSON M.T 2, ONE OF THE DIFFERENT TYPES OF MILITARY AIRPLANES DESIGNED AND BUILT BY THE LAWSON AIRCRAFT CORPORATION DURING THE WAR

The AIRCRAFT TRADE REVIEW

Government Orders Loening Monoplanes

The first Government peace time order for aeroplanes has been placed by the U. S. Navy Department with the Loening Aeronautical Engineering Corporation, New York City, for the immediate delivery of six special Loening Monoplanes which are to be used in the Navy Department for shipboard observation use.

Recent experiments started just prior to the close of the war, and continued for several months thereafter, have disclosed the remarkable efficiency with which fast high powered aeroplanes can be used by the Navy Department for observation and spotting of gun fire of the battle-ships. The Loening Monoplane, a new type of two-seater fighter, which was designed by Grover C. Loening, formerly chief aeronautical engineer of the Army Air Service, was accepted by the Government just prior to the armistice, and after official tests was found to be the fastest and best performing two-seater fighter in the world. Several records for speed and altitude have been broken in the official trials by Major R. W. Schroeder of the Army Air Service.

The machines for the U. S. Navy will be so equipped as to permit of launching off the deck of a ship, as it has been found that the light monoplane type of machine can be accelerated very quickly particularly when equipped with a motor as powerful as the 300 Hispano Suiza, which is being used on this type of craft.

Curtiss Company Buys 2,176 Planes and 4,608 Motors

A deal by which the Curtiss Aeroplane and Motor Corporation repurchases from the Government 2,176 aeroplanes and 4,608 motors made by it during the war was announced on May 25 by W. W. Mountain, vice-president and general manager of the company.

This deal had been reported at various times as about to be consummated, but had always fallen through each time before. The contract was signed for the War Department by Major-Gen. Charles T. Menoher, head of the air service, and by G. M. Keyes, a vice-president of the Curtiss concern.

The price was not announced by Mr. Mountain, but it is known that in previous negotiations the Curtiss company refused to buy the planes and motors for $2,720,000 unless the Government agreed not to dispose of other Curtiss planes or motors to private purchasers for two years. It is probable, however, that the price paid is about 10 per cent. of the original figure.

Included in the deal are 1,100 standard aeroplanes which the Curtiss people did not build, but which they are buying in order to get back the Curtiss motors with which they are equipped.

J. A. Callahan Sped Up Curtiss Production 400 Per Cent.

Speeding up an aeroplane production programme from an output of a little more than a hundred to more than four

Mr. J. A. Callahan, manager of motor production at the Churchill plant of the Curtiss Company

hundred a month in a year's time is the record that J. A. Callahan, factory manager of the Curtiss Aeroplane and Motor Corporation, and his organization at Buffalo made during the war period.

During the month of July, 1917, the Curtiss plants, comprising the Churchill Street group, produced 139 aeroplanes for the government.

The output, however, was insufficient and almost daily came requests from the government to "speed up."

On the 31st of July, 1918, Mr. Callahan had increased the production of the plants under his jurisdiction to such an extent that the 400th plane was crated and shipped.

Mr. Callahan was born in Lockport, N. Y., in 1884. After completing his high school education he went to Buffalo, to work with the Thomas Motor Company, where he advanced to manager of stores. Following this he was connected with the T. A. Gillespie Contracting Company, Russell Motor Car Company and Goodrich Tire and Rubber Company.

In 1915, he was made assistant superintendent of the Churchill street plant of the Curtiss company. In a short time, he was made assistant to K. B. MacDonald, then vice-president and general manager of the company. He then took charge of the despatching for all operations and of the keeping of factory records and finally became manager of the Churchill Street group.

Between January 1, 1917, and January 1, 1918, the factories comprising this group made and shipped 1,441 aeroplanes. From January 1 to August 1, 1918, this same group shipped a total of 2,365 machines of the preliminary and advanced training types and specbial models.

After the armistice was signed, the directors of the company decided to concentrate all efforts in combining all of the Churchill Street group—the Bradley, Niagara, South Elmwood and Churchill factories—into one and the Churchill plant was selected.

Mr. Callahan is now in charge of the motor division at the Churchill plant, in addition to the aeroplane division, and the plant is now producing the famous K-6 and K-12 motors in quantity and also the new three-passenger Curtiss Oriole.

Wright-Martin to Get Order for Hispano Motors

New York, May 15.—It is reported, according to *Automotive Industries,* that the Government shortly may place orders with the Wright-Martin Co. for a quantity of Hipsano-Suiza engines. It is stated that the order may amount to $5,000,000.

Aircraft Claims Being Gradually Settled

Washington, D. C.—Slow progress is being made in the settlement of claims against the War Department. All of the big aircraft claims are still out and may not be filed for some time. Approximately 40 per cent of the total of aircraft claims in this district have been approved at Washington. Thirty per cent are now before the board and 30 per cent remain to be filed. Officials of both boards, however, predict that settlement matters will move rapidly from now on. Many points which have been holding back claims have been cleared up at Washington and new regulations are greatly simplifying the work of the board.

National Wire Wheel Works Moves to New Hagerstown Plant

Hagerstown, Md.—The National Wire Wheel Works, Inc., has moved its main office to Hagerstown, Md., where the principal plant of the company is located. The offices heretofore had been located at Geneva, N. Y.

Champion Spark Plug Company Assumes Federal Tax

Toledo, O.—The Champion Spark Plug Company was one of the first manufacturers of automotive equipment to go on record as to how they would handle the new revenue tax of 5% levied on all automobile accessories under the Federal Excise Tax Bill.

On February 27, two days after the bill became effective, the Toledo concern sent a wire to its jobbers throughout the United States advising that the Champion Company would pay the 5% tax and that there would be no change in the price to dealers. The tax is therefore not passed on to the consumer.

P. O. Dept. Preparing New Newark Landing Field

Washington, May 16.—It is stated at the Post Office Department that the government had decided to go ahead with the preparation of an aviation field on the Heller property in Newark.

A contract has been let for the preparing of a sufficient space in the Heller tract to permit the landing and starting of the aerial postal planes.

Swiss Aerial Mail Service Planned

An aerial postal service is to be organized this summer between St. Gall and Geneva, passing by Zurich, Berne and Lausanne. A tax of 50 c. per letter will be imposed. The service wil only be temporary, experience having shown that good results are obtained even when the distance is over 600 kms.

Air Mail Pilot E. H. Lee Trained Many Stunt Fliers for Air Service

Aerial Mail Pilot E. Hamilton Lee took his first lesson in the handling of aircraft at Fort Snelling Field, Minneapolis, Minn., flying a Curtiss "pusher," and later graduated from the Partridge Tractor School at Cicero Field, Chicago.

When the United States took up arms against Germany, Lee offered his services to the Government and was made flying instructor at Ashburn Field, Chicago, at the time the Fourth Aero Squadron was receiving its training there.

September 13, 1917 he was transferred to Selfridge Field, Mt. Clemens, Mich., as an instructor in stunt flying. On December 15, 1917, Lee made the last official flight of the year at this field, this being the closing day. The weather registered 18 degrees below zero, and the snow was 4 feet deep. A runway was cleared for the landing. The duration of the flight was 11 minutes.

December 23, 1917, Lee arrived at Ellington Field, Houston, Texas, and was an instructor of dual training. February 21, 1918, Ellington Field started a stage of acrobatic flying. Lee was chosen as the first instructor assigned to the stage,

(*Continued on page* 591)

Air Mail Pilot G. G. Budwig, formerly advanced acrobatic instructor in the Air Service, is now testing De Haviland Mail Planes

OTTO PRAEGER, Second Assistant Postmaster General.

NAVAL and MILITARY AERONAUTICS

A. E. F. Trained 2,525 Pilots and Observers

Washington, D. C.—According to a statement recently issued by the statistics branch of the General Staff, to the date of the armistice 2,525 pilots and observers were graduate from the A. E. F. advanced training schools, 77 per cent of whom were sent to the Zone of Advance.

The numbers shown in the following table are cumulative and cover the period from the beginning of the war to November 13, 1918:

Enrolled in training courses....	5,429
Graduated	2,525
Sent to Zone of Advance.....	1,940
Losses in Zone of Advance....	570
Losses in training	450

Arcadia Balloon School Named Ross Field

Washington, D. C.—The Army Balloon School at Arcadia, California, has been officially designated as "Ross Field" in honor of Lieutenant Cleo J. Ross, Air Service, killed in France near Brabrant, September 26, 1918.

Air Service Troops Rapidly Returning

Washington, D. C.—On May 8 there were 19,747 Air Service Troops on duty in the United States, and 28,718 overseas. The net decrease of personnel of air service from November 11 to May 8 is 75 per cent.

The Kelly Field Altitude Record

Lieutenant Fields, Jr., has added 500 feet to the altitude record made by Lieutenant Sweeley, who with Lieutenant Boggs as official observer soared to a height of 20,100 feet. The record will be submitted to the Aero Club of America for homologation under the rules of the International Aeronautic Federation.

War Department Instruction Manuals Available

Washington, D. C.—The War Department News Bureau has a set of instruction manuals issued by the Committee on Education and Special Training, available for examination, covering the following subjects: Auto mechanics and drivers, sheet metal workers, carpenters, telephone electricians, surveyors, machinists and farriers.

Major Mannack Britain's Champion Air Fighter

The Air Ministry has decided that so far as can be ascertained the champion British airman of the war was the late Major Edward Mannock. Lieutenant Colonel William A. Bishop, the Canadian aviator, who won the Victoria Cross, comes next. Major Mannock brought down 73 enemy machines, and Lieutenant Colonel Bishop, 72.

Of all the Allies, Lieutenant Rene Fonck, the French ace, holds the record, with 78.

Major Mannock was born in India of British parents, thirty years ago, and was considered the greatest aerial tactician the Royal Air Force produced. Among his awards was the War Medal of the Aerial Club of America.

All Emergency Men to Be Discharged by Air Service

Washington, D. C.—The War Department authorizes publication of the following information:

The Director of the Air Service is being directed to discharge from the service, with the least practicable delay, all emergency men now being held in the service at camps and stations in the United States for purposes of training except those in the 29th Balloon Company at Ft. Monroe, Virginia. The discharge of emergency men from the latter organization will not be effected for the present except those eligible under the provisions of Circular 77, WD, 1918.

Ruling on Promotions Made

Washington, D. C.—Circular No. 79, W.D. 1919, covering promotions for the period of the emergency within the United States and its possessions, has been revoked. Hereafter promotions will be made to give ranks appropriate to the command in case of line officers or to actual employment in the case of staff officers.

No officer is to be recommended for promotion unless the duty upon which he is engaged is commensurate with the advanced grade recommended and unless there is no officer of appropriate rank reasonably available for assignment to the duty in question. In addition to such vacancies as may be computed by the Chief of the Personnel Branch, of the General Staff, a vacancy may be considered to exist in any grade where the interests of the United States make such promotion necessary. No promotions will be made without personal approval of the Secretary of War.

Overseas Chevrons Computed from Embarkation

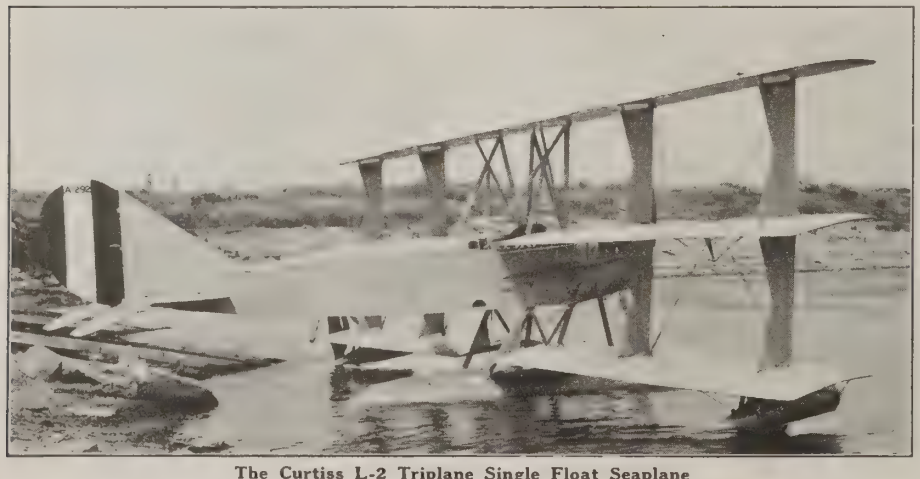
The Secretary of War has issued directions that the computation of time for overseas war service chevrons shall include all time from the date of departure from the Port of Embarkation, U. S. A., to date of arrival at Port of Debarkation, U. S. A., both dates inclusive.

Aero Squadrons Designated for Philippine Service

Washington, D. C.—The following observation squadrons are being organized with a view to their later transfer to the Philippine Islands: 2nd Aero Squadron, Rockwell Field, San Diego, Calif.; 3rd, 4th and 5th Aero Squadrons at Hazelhurst Field, Mineola, L. I., N. Y.

All enlisted men assigned to these organizations will have at least two years to serve in their present enlistment period and no man enlsted or drafted for the emergency will be retained in the service to assist in organization of these units or on account of their organization.

Army Seeks Aerial Photographers



Washington, D. C.—A campaign for the recruiting of aerial photographers has been begun by the War Department. Many inducements are offered to recruits and the chances of advancement in the service are excellent, and flying pay is offered to those whose duties require frequent and regular flights. After one year of service, unmarried soldiers under thirty years of age are eligible to the grade of Provisional Second Lieutenant. Enlistments are for one or three years. Information can be obtained from any recruiting office, or from the Office of the Director of Air Service, U. S. A., Photographic Branch, Washington, D. C.

Colonel Culver Receives D. S. M.

The Distinguished Service Medal has been awarded to the following officers:

Colonel C. C. Culver, U. S. Army, for exceptionally meritorious and conspicuous service. To Colonel Culver's untiring energy, close application and perseverence is due the credit for having completed the coordination of the chain of events leading from the earliest conception of the Radio Telephone to the successful accomplishment of Voice-Commanded Flying carried through to full frutiion.

Mr. Nugent H. Slaughter, formerly Lieutenant Colonel, U. S. Army, for exceptionally meritorious and conspicuous service in the very successful development of the radio equipment of the United States Army.

The Curtiss L-2 Triplane Single Float Seaplane

Mr. Brice P. Disque, formerly Brigadier General, U. S. Army, for exceptionally meritorious and distinguished services rendered in connection with the organization and administration of the Spruce Production activities of the Bureau of Aircraft Production, while serving as officer in charge of the Spruce Production Division and President of the United States Spruce Production Corporation.

Field Officers Who Change Station

The following named field officers have been ordered to change station as follows since May 5, 1919:

Colonel Henry H. Arnold, J.M.A., A.S.A., ordered from Rockwell Field, San Diego, Calif., to San Francisco, Calif., for duty as Department Air Service Officer.

Colonel Joseph C. Morrow, M.A., A.S.A., ordered from Washington, D. C., to Chicago, Ill., for duty as Department Air Service Officer.

Colonel James E. Fechet, J.M.A., A.S.A., ordered from Kelly Field, San Antonio, Texas, to Fort Sam Houston, San Antonio, Texas, for duty as Department Air Service Officer.

Colonel Gerald C. Brant, A.S.A., ordered from Ellington Field, Houston, Texas, to New York City, N. Y., for duty as Department Air Service Officer.

Lieutenant-Colonel Leonard H. Drennan, J.M.A., A.S.A., ordered from Chicago, Ill., to Boston, Mass., for duty as Department Air Service Officer.

Special Orders Nos. 114 to 119, Inclusive

The appointments on April 7, 1919, of the following Air Service officers, for the period of the existing emergency, are confirmed. To be major, Air Service: Capt. John W. Swann.

To be captains, Air Service: First Lieuts.: Fenton J. Baker, Arthur Mason DuBois, Edwin H. Fort, Ballard W. George, Edward Glik, Isaac Morley Griswold, Cecil Hewitt, Thomas H. Hiltz, Bruce C. Hopper, Frank H. Johnson, Thomas D. Jordan, Morse B. Kent, Geoffrey C. Maxwell, Howard J. Meyer, Lewis Joseph Newman, Walter Jay Reed, James Wade Rockwell, Raymond C. Sanborn, Stanley P. Smith, Patrick H. Whittington, Samuel J. A. Wifvat, William A. Williams, Edgar Youngdahl.

To be first lieutenants, Air Service: Second Lieuts. Carl R. Bass, Frederick W. Borchers, Fred W. Clark, Murry H. Eckman, Henry U. Farnsworth, Charles S. Gilbert, Robert Corbould Green, James F. Haldeman, Frank Duncan Kelley, Samuel Roger Klubock, Charles Howard La France, Joseph A. Lowery, John F. Malone, Stanley Nowlen, Frank Herbert Prem, Merwyn Colvin Randall, William N. Reagan, William H. Reese, Henry D. Roberts, John Howard Robinson, Richard H. Scott, Jr., Robert Steinberger, Clarke S. Sutherland, George Lear Tomlinson, Paschal Williams, Roy D. Witmer.

The appointments on April 9, 1919, of the following-named officers, Air Service, for the period of the existing emergency, are confirmed: To be captains, Air Service: First Lieuts. Russell V. McMurphy, John Robert Harman, James W. Stokes.

The appointments of the following-named Air Service officers, for the period of the existing emergency, are confirmed: To be major, Air Service: Capt. Henry John Whitehouse. To be captain, Air Service: First Lieut. Bertram Winthrop.

To be major, Air Service: Capt. Alvin C. Reis. To be captains: First Lieuts. Dogan Humphries Arthur, William Henry Carthy, Harvey Weir Cook, Russell Stewart Dean, Howard T. Douglas, Clifford E. Gregory, Edward Grotecloss, Jr., Horace Moss Guilbert, Edmund A. Hastings, Phil A. Henderson, Charles C. Hicks, Samuel Kaye, Jr., George Churchill Kenney, John H. Lambert, Richard C. M. Page, Robert C. Paradise, Roy S. Ripley, William C. Thomas.

To be first lieutenants, Air Service: Second Lieuts. Emil L. Balfay, Joseph Francis Becker, Edward Crews Black, George Raymond Cullman, Roy U. Dabbs, James L. Davitt, Edward Keenan Delana, Oswald A. Eckhardt, Sidney Bradford Grant, Charles P. Harrington, John W. Jordan, Otto D. Trunk, Robert Wilson Watt, Clement Edwin Kennedy, William Henry Leininger, Paul Jones Mathis, John Michael McDonnell, Charles W. Richard, Verner Delane Sapp, Howard Smith, Bruce Struthers, Eugene E. Stuck, Alexander Tolchan, Curtis Wheeler.

Maj. Carl Spatz will proceed from Rockwell Field, San Diego, Cal., then to Taliaferro Field, Hicks, Tex., take station there, assume command. Report by letter to the Director of Air Service, Washington, D. C.

First Lieut. John W. Dissette, Air Service (Aeronautics), promoted to captain Air Service (Aeronautics).

Second Lieut. Isaac B. Van Devanter, Air Service (Aeronautics), promoted to first lieutenant, Air Service (Aeronautics).

Capt. Lee W. Felt, Air Service (Aeronautics), now at Post Field, Fort Sill, Okla., will proceed to Washington, D. C., on temporary duty not to exceed five days; thence to San Francisco, Cal., and report in person to the general superintendent Army Transport Service, Fort Mason, for transportation to Honolulu, Territory of Hawaii, on transport leaving San Francisco about June 5, 1919, reporting upon arrival to the commanding general Hawaiian department for duty.

First Lieut. Alfred W. Marriner, Air Service (Production), will proceed to Washington, D. C., for temporary duty; thence to San Francisco, Cal., and report to the general superintendent Army Transport Service, Fort Mason, San Francisco, Cal., for transportation to Honolulu, Hawaii, reporting upon arrival to the commanding general Hawaiian Department.

First Lieut. Frank B. Tidwell is announced as on duty requiring him to participate regularly and frequently in aerial flights from November 5, 1917.

First Lieut. George D. Litherland will proceed to San Francisco, Cal., and report to the general superintendent Army Transport Service, Fort Mason, for transportation to the Philippine Islands, reporting upon arrival to the commanding general Philippine Department.

A board of officers to consist of Lieut.-Col. Arthur J. Hanlon, Maj. Albert D. Smith, and Maj. Emmett I. Vaughn (Medical Corps), is appointed to meet at Rockwell Field, San Diego, Cal., at the call of the senior member of the board for the purpose of examining officers ordered to appear before it to determine their qualifications for rating as military aviators or junior military aviators.

The board of officers consisting of Maj. Theodore C. Macauly, Capt. Richard D. Gile, and Capt. R. W. Pope (Medical Corps), appointed by par. 394, S. O. No. 195, W. D., to determine their qualifications for rating as military aviators or junior military aviators, is dissolved.

First Lieut. Rene R. Studler will proceed to Aberdeen Proving Grounds, Aberdeen, Md., and report for duty with 271st Aero Squadron.

First Lieut. Bertram E. Giesecke will proceed from School of Military Aeronautics, University of Texas, Austin, Tex., to Kelly Field, San Antonio, Tex.

First Lieut. Alfred R. Bellinger will proceed to Washington, D. C., and report to the Director of Air Service.

Maj. Howard F. Wehrle will proceed to Washington, D. C., for temporary duty, thence to Air Service Mechanics' School, St. Paul, Minn., and assume command.

The following-named officers, now at Akron, Ohio, will proceed to Langley Field, Hampton, Va.: Capt. Raymond C. Pierce, Capt. Elden P. Phillips.

Second Lieut. Allen B. Humason will proceed to Carlstrom Field, Arcadia, Fla.

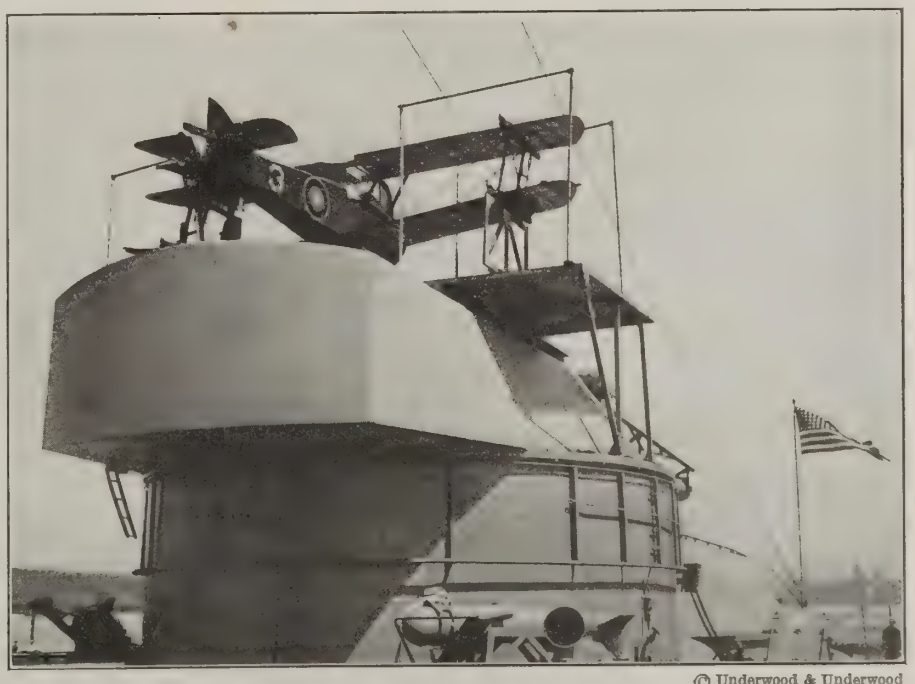
Second Lieut. Charles F. Curry, Jr., will proceed to Washington, D. C., and report to the Director of Air Service.

First Lieut. Frederick W. Evans will proceed to Army Balloon School, Lee Hall, Va.

Second Lieut. John L. Day is detailed for duty with the Medical Department, and will proceed to Chicago, Ill., U. S. A. General Hospital 32.

First Lieut. Walter J. Enright to Washington, D. C., and report to the Director of Air Service.

Second Lieut. Laland M. Baum report to Army Balloon School, Lee Hall, Va.



(*Continued from page* 589)

breaking in other flyers for instructors in stunts. June 10, 1918, he climbed to a height of 12,100 feet and made 105 consecutive loops landing out of the last one, using a JN4B Curtiss plane and motor (OX-5). On several occasion he flew from Ellington Field to Angleton, Texas, on hunting trips and fly back 12 or 1 o'clock at night, a distance of 75 miles. Lee has flown 15 different types of planes and 8 different types of motors.

Some of the Government aviators whom Lee has trained have won distinction in service at the front, one being Lieut. Ralph E. deCastro, who won distinguished war cross for bravery over the lines September, 1918, and he was formerly associate editor of AERIAL AGE .

Lee is credited with 3,000 hours of flying, 1,000 of which were spent in acrobatic flying. Barring an accident occurring during a heavy fog with no visibility and entirely beyond the control of the aviator, Lee's record is of the best, never having had an accident until April 4, 1919, mentioned above.

Pilot E. Hamilton Lee entered the air mail service on December 29, 1918, and has an excellent record for reliability in the delivery of his cargo.

FOREIGN NEWS

Route of French Aerial Touring Contest Announced

The provisional list of stages in the preliminary trials in connection with the safety and comfort competition for which the "Echo de Paris" is offering $60,000 is now available. Starting from Paris, stops will be made at the following towns in France and neighboring countries: Nantes, Bordeaux, Toulouse, Barcelona, Nimes, Turin, Avignon, Geneva, Strasbourg, Brussels, London, and so back to Paris. Brief halts will be made at other places between these points.

Aeroplane Part of Antarctic Expedition Equipment

It is proposed to include an aeroplane in the equipment of the expedition to the Antarctic which is to be made under the leadership of Mr. John L. Cope, F.R.G.S., who accompanied the Imperial Trans-Antarctic Expedition, 1914-17, as surgeon and biologist to the Ross Sea party.

The expedition will leave this country in June, 1920, in the "Terra Nova," and return in 1926.

Inter-Scandinavian Flying Week

From the results of the recent Inter-Scandinavian Flying Week, according to *Flight*, it would appear that the Norwegian pilots made the best showing. A Danish aviator covered the greatest distance by flying from Copenhagen to Slagelse, a distance of 850 kilometres. Two Norwegian aviators came next, each flying over 775 kilometres over land and water on unfamiliar routes. The Swedish aviators did not complete the course. Of six Danish aviators only two finished. All the Norwegian aviators finished their flights.

Brackpapa Ascends 23,786 Feet with Three Passengers

Turin, Italy.—Lieut. Brackpapa, an Italian aviator, in an aeroplane with three passengers ascended on May 21 to a height of 7,250 metres (23,786 feet). The ascent was made in forty minutes.

French Aviator Reaches 28,800 Foot Altitude

PARIS, May 21.—The aviator Sadi Lecointe yesterday ascended to a height of 8,800 metres (28,871 feet), at the Villacoublay aerodrome, establishing a French record for height. This is only 29 feet short of Major Schroeder's record.

Aviator Delivers Lecture from 5,000 Foot Altitude

LONDON, May 16.—At an altitude of 3,000 feet a British aviator gave a lecture by wireless to members of the Institute of Electrical Engineers assembled in a hall in London, says a copyright dispatch to the New York Sun.

After describing the flight from his position in the air the aviator ended by saying he was "fed up" and rang off. This is the latest aeroplane wireless sensation.

Air Ministry Reports on Expenditures

A few details of the expenditure of the old Air Board and the Air Ministry (which succeeded the Air Board on January 3, 1918) during the year ended March 31, 1918, have recently been issued, as follows: Total expenditure, $10,763,679.20, which was expended under the following heads: Salaries, wages and allowances, $499,958.70; travelling expenses, $19,840.10; miscellaneous stores, $41,919.70; incidental expenses, $47,946.15; works and buildings, $11,597.20.

African Factory Contributed to British War Production

The works of the Maison J. Donnet at Sidi-Abdallah, Ferryville, Tunis, which are managed by Mr. Jeltés, and have turned out a number of Donnet flying-boats during the war, almost entirely by means of Moorish labor. The boats are assembled in the sheds and mounted on trollies on a railway. When passed as ready for use the engines are started and the machines propel themselves under their own power along 1,000 metres of railway down to the Lagoon of Bizerta, where they are launched direct off the trollies.

Martinsyde Plane Flies from London to Paris in 75 Minutes

London.—A new record for the London-Paris flight has been established. Starting with dispatches from Hendon Aerodrome at 3:20 P. M. on April 8th, and following the Dieppe route, involving a sea crossing of 70 miles, the pilot landed at Paris (Buc) in one hour and fifteen minutes after his departure.

As the distance from point to point is 215 miles, the average ground speed of the machine was 172 m.p.h. The machine was a Martinsyde single-seater scout, fitted with a 275 h.p. Rolls-Royce "Falcon" Mark III.

Lyons to Turin in 2½ Hours

Leaving Lyons in a gale, three Italian military pilots, in a 600 h.p. aeroplane, on April 23d flew across the Alps and landed safely at Cambiano, near Turin, the trip having taken two and one-half hours. On the way they encountered a heavy snowstorm.

Argentina Sends Aeronautic Mission to Great Britain

On May 5th there arrived in England an Argentine aviation mission composed of Captains Brihuega and Zuluaga and Engineer Paravella. The mission will visit most important flying schools and factories.

To Cover Vaudeville Circuit by Air

According to a British aeronautical journal, Mr. Frank Allen, managing director of Moss Empires, Ltd., has asked a well-known aircraft company to supply him with a machine capable of carrying two passengers and pilot at 100 to 120 miles per hour, for service upon the Moss' Tour throughout the United Kingdom, embracing over thirty variety theaters.

As soon as the official ban upon commercial and private flying is removed an experimental flight will be made.

Madrid-Seville-Madrid Flight in 4 Hours

Major Geoffrey de Havilland, R.A.F., who is sojourning for a time in Spain, has flown from Madrid to Seville and back, a distance of 480 miles, in four hours.

The machine used by Major de Havilland while giving exhibitions of flying was a De H 9 biplane with a 450 h.p. Napier engine. Major de Havilland is well known as the designer of the famous Airco machines.

Aerial Transport for Portugal

An aeroplane service will fly this summer between Barcelona and Lisbon via Madrid, Oporto, and Coimbra.

5,000 Farman Planes Tested Without Accident

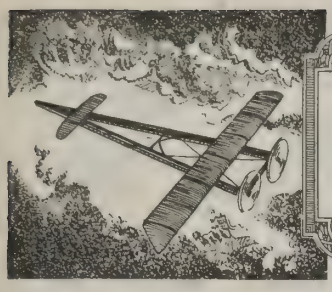
Paris.—As evidence of the safety and reliability of aircraft, the record of Farman brothers, famous aeroplane construction, is of interest. All three brothers fly regularly, and M. Dick Farman daily. During the whole period of the war they have not had an accident to either pilot or machines in their reception tests or subsequent delivery to the army, and they supplied well over five thousand!

Chinese Government Orders Handley Page Planes

London.—The Handley Page Company has received an order through its agents, the Pekin Syndicate, for the supply of machines and personnel to the Chinese Ministry of Communications.

The first machines sent out will be of the twin-engine biplane type adapted to seat ten passengers and to carry 1,800 pounds of cargo. Experts and pilots be supplied, and the construction of aerodromes will be undertaken.

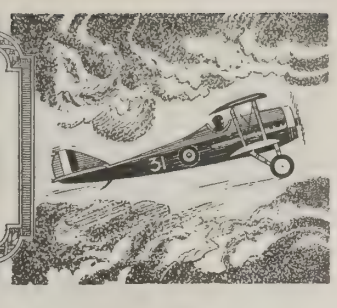
Austrian Lohner Flying Boat, many of which have been surrendered to the Italians



Brussels-London-Paris-Brussels Flight in 7 Hours 20 Minutes

Piloted by Lieutenant Georges and carrying two passengers, a Belgian two-engined army aeroplane has accomplished a circular flight from Brussels to London and Paris and back to the starting point, about 570 miles, in 7 hours, 20 minutes actual flying time.

First Cargo Carried in Foreign Trade by Aeroplane Reaches Havana



Havana, May 20.—The seaplane Sunshine, the first seaplane chartered for freight-carrying purposes between the United States and Cuba, arrived here on May 22 with a cargo of soap. The Sunshine was chartered by S. S. Friedlein, a Havana merchant, and the cargo came on a regular manifest with consular papers similar to those issued to ships.

The cargo did not pass the Havana Custom House, however, because the seaplane landed at Marianas Beach, and the holiday bathers there raided the plane and seized its entire contents as souvenirs. The aviators were an American, John Green, owner of the Sunshine, and Augustin Parla, a Cuban, formerly of the Cuban Army.

ELEMENTARY AERONAUTICS and MODEL NOTES

By John F. McMahon

Pacific Model Aero Club Contest

The Pacific Model Aero Club is now an auxiliary of the Pacific Aero Club and have just completed a very successful meet. Mr. Irvine of the senior Club is one of the board of directors of the junior body, as well as Mr. W. F. Hopkins, a gasoline motor designer, Mr. Mehre, a manual training instructor, and Mr. H. E. Hansen, brother of the President of the model club. It is the rule of this club that all members of the board of directors must be over 21 years of age.

The following officers of the new club hold office for one year from April 30, 1919:

Raymond C. Hansen, President; Theodore Morse, Vice-President; J. Laurence Irwin, Secretary, and Ray Ashley, Treasurer.

This club has signified its intention of starting in the Aerial Age Model Aeroplane contests and have entered the following team: Noble Heuter, Earl Vivell, Theodore Morse, Ray Ashley, Ralph Vincent, Laurence Pinkpank, Preston Hopkins, George Mullins, Raymond Eying, Edward Mascone, Raymond Fife, of Venice, Cal.; Daniel Tuthill, of Oakland, Cal.; Cleon Calway, of Valego, Cal.; George Ashley, Howard Morse, Raymond Hansen, Fred Geryine, Joseph Gutman, Laurence Irwin, Harold Hansen and Heubert Burgess.

The accompanying photographs show a meet being held by the club at one of the San Francisco parks, and the President, Raymond Hansen, holding his record breaking model.

This model has a span of 58 inches with a 7-inch chord, and double surface of gold beater's skin for covering. The front or elevating plane has a 20-inch span with 4½-inch chord and is single surfaced, being set at a greater angle of incidence than the main plane. The propellers are 18 inches in diameter and are cut from planks⅞x1⅝". The frame is 60 inches long. The wing spars are 3/16x¼" at the center and tapered to ⅛" at the ends. The ribs are located every 2½ inches and the trailing edge is made of 1/32x3/16" spruce. The wing tips are of thin bamboo strips. The bottom curve of the wing is slight, being only ⅛". The Lauder type of brace is used for protecting the machine in flight from buckling from the strain of the rubbers. Ten strands of 3/16x1/32" flat rubber are used on each propeller.

Although the model is large, it is a fast flier and very stable. It generally climbs to 150 feet at the start of its flight before straightening out. With only half the number of turns in the rubber motor it flew 2500 feet and had a duration of 100 seconds on the first tryout. On the second attempt with the same number of winds it flew 3000 feet and 110 seconds. The flights averaged 2000 feet and 100 seconds for the day's flights.

After the contest it was again tried out near the model owner's home and it quickly rose to 300 feet and helped by the wind disappeared over Golden Gate Park after circling around in the air for about four minutes.

Another copy of this model was built with 24" propellers but it broke in the air under the strain of a heavy wind.

A picture of this machine in flight high in the air was received, but it would not stand reproduction as it was too faint.

Theodore Morse flew a model weighing only 1.50 ounces for 2500 feet in 100 seconds. The propellers were 10 inches in diameter. Three strands of 3/16x1/32" flat rubber was used on each propeller. The main plane measured 25x5" and the front plan 10x3".

More is expected of this Club and I would not be surprised to see them well up in the contest for the Aerial Age prizes.

Although they are a new club, they have made wonderful strides and, from their records, they will soon be at the heels of the Illinois Model and Aero Science Clubs.

It is interesting to study the model shown in Mr. Hansen's hands. A beginner generally starts building the tiniest model he can think of, and wonders why good results are few and far between. Later he gets a glimpse of a successful model of the flying stick type and from that time on, improvement is rapid as will be noted from the results received from most of the smaller clubs in the country.

The model shown here is the right type of racing model and a good one to copy. The Lauder model shown last week is the forerunner of this kind of model, as are those built by the Chicago boys for the past two years.

The Christofferson Junior Biplane

The little machine shown in the cut to the right was built by H. P. Christofferson, San Francisco, Cal., in such a way as to be inexpensive and simple to construct. No expensive material is used and no wires or fittings are used in the fuselage in back of the pilot's seat.

The wing spread is 25 feet, and the length 16½ feet. The chord is 4 feet and the gap 4 feet 3 inches. The fuselage is built up of plywood sections. The complete weight is only 275 lbs. The power plant is an ordinary Indian motorcycle engine, with standard cams, ports, etc. A reduction gear allowing the engine to turn up to 3000 to the propeller 1200 R.P.M. is used. Overheating was eliminated by the use of deflecting plates of sheet metal attached to the motor. This machine was built for the price of a good motorcycle, or about $400. It has 175 square feet of surface, and a speed of 40 miles per hour. It has stick and foot bar control.

It is easy to construct and easy to handle for a novice who wishes to teach himself to fly. The wheels are 20x1⅝" and the tires double tube clinchers. The landing gear is made of steel tubing and fitted with shock absorbers. It has a two-gallon gravity tank over the engine.

The machine is shown well up and apparently flying with ease and without trouble.

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

(Dear Reader:—We have tried to keep you fully informed on the subject of prohibition and aeronautics. Our esteemed British contemporaries have devoted considerable space to the subject. We take pleasure in presenting to you the musing of Aubrey England written after reading of the establishment of the passenger carrying service to the Bahamas, as published in *Aircraft.)*

In the morning, feeling thirsty, to my hangar I repair,
Get my spad out, tune the engine, take her leaping through the air;
Leave the "ferry" singing gaily, full of hope and full of cheer,
There's an inn in the Bahamas where I know they sell good beer.

Prohibition nearly killed me—many a noble man it's slain;
But I laugh at all life's worries, since I bought my aeroplane.
There's a girl who's waiting for me, and can hear me from afar,
Standing waiting with a beaker by the barrel in the bar.

There's no rule was ever written that the pen could not erase,
And so long as I'm a flyer I can beat the latest craze,
Speed my 'plane to the Bahamas, where in joy I'll glide right down
To the beer of good Old England in a tavern in the town.

—*Aubrey England.*

Old Mother Hubbard

Old Mother Hubbard went to her hangar
To give her pekinese his morning spin
But when she got there
The hangar was bare
For a thief in the night had got in.

Little Jack Horner
Is now quite a goner
From flying too awfully high;
He was heard to condole,
After he'd lost all control,
"What a doggone fool am I."

Clergymen Protest Against Sunday Flying

Washington, D. C., Friday (Associated Press dispatch).—The Sunday observance issue raised by the protest of churches and clergymen in many cities against flying circuses and exhibition of moving pictures in connection with the Liberty Loan was met by the Treasury in a decision to leave the question to each community affected. The Treasury has been flooded with protests against Sunday flying.

(In this connection, attention is called to the sin of breathing the air on Sunday. While this sin is not as flagrant as the one mentioned above, it should receive the attention of our guardians of morality).

Facing the Inevitable

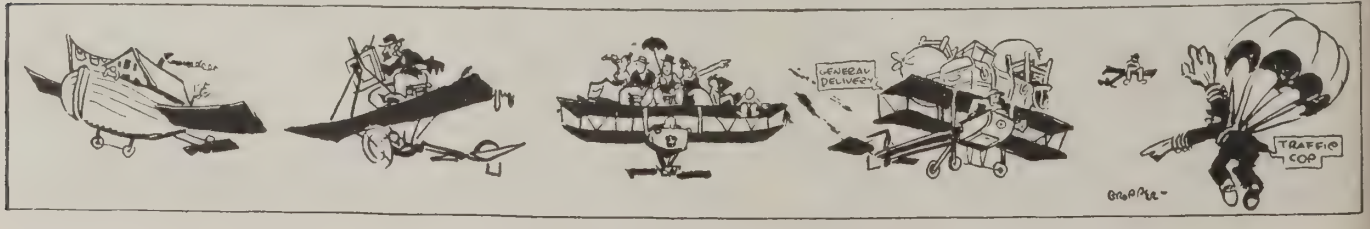
"Jim," said the pilot, "we're going to do it; I can see the outlines of dear ould Oireland."

"That's so," mused the observer. "We've crossed the Atlantic; but why are you so melancholy about it?"

"I'm thinking of all those reporters who'll be waitin' for us. What am I going to tell 'em, Jim? Fact is, I can't remember having done an eventful thing in my life."—From *Aircraft.*

Late News from Count Zeppelin

"Whew! But it is hot. I wish I had one of my airships to fly away in."



"You shut up, Count Zeppelin," said his Satanic majesty. "You know as well as I do that your gasbags met hell halfway to Britain and couldn't stand it. What's the good of talking about impossibilities?"—*Aircraft.*

I asked my mother for fifty cents
To fly in an aeroplane over a fence,
But it flew so high, that it reached the sky,
And never came back till the 4th of July.

There was a young lady named Hopter,
Who invented a new helicopter;
She rose up all right:
When she tried to alight,
It made for a ditch, and there flopt 'er.

—From *Aircraft.*

Hey diddle diddle, my plane is a divvil
And with it I'll hop o'er the moon;
Other pilots may laugh and hand me the gaff
But I'll show them all up very soon.

When aeroplanes become so common that they do not bother the man with a boil on the back of his neck

VALENTINE'S
VALSPAR
The Varnish That Won't Turn White

Lewis and Vought *insisted* on Valentine's finishes

HERE is a letter from the Lewis and Vought Corporation, of Long Island, N. Y., successful manufacturers of Training Planes, that speaks for itself:

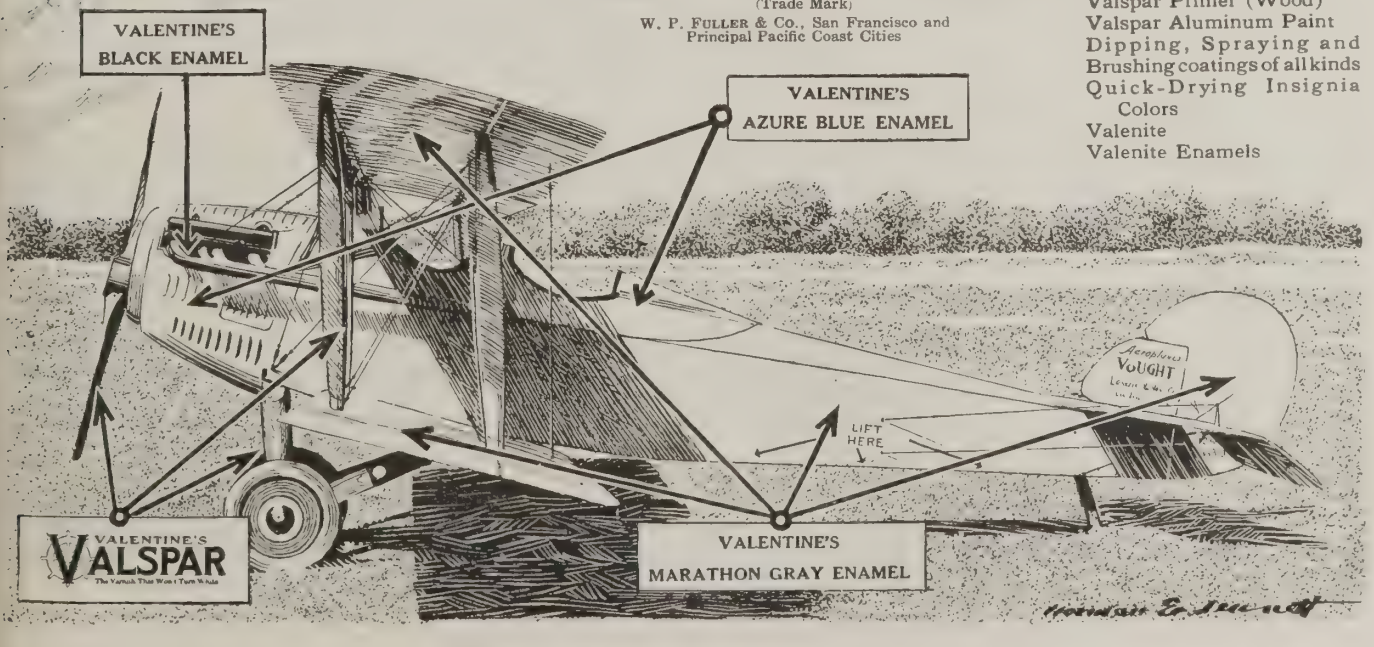
"As you know, the Vought VE-7 Airplane, designed by Mr. Chance M. Vought, was adopted by the U. S. Government for its standardized advanced training airplane to displace other types in use or on order.

"We insisted, in the Government specifications as standard finish of these machines, that the following Valentine products be used:

"Wood parts: Valentine's Wood Filler, and Valentine's Valspar;

"Exterior Metal Parts: Valentine's Blue and Black Enamel (baked on);

"Interior Metal Parts: Valentine's Valspar;



"Fabric Finish: Valentine's Special Marathon Gray Enamel."

Other Airplane Engineers and Production Superintendents are learning to *insist* on Valspar Varnish and other Valentine finishes because they have learned that they can depend upon them.

Aircraft Advertising Agency, Inc.

280 Madison Avenue
New York

Telephone 1556 Vanderbilt
Cable Address: "Aero-Ads"

"AERO-ADS"
by
"AERO EXPERTS"

THE members of the *Aircraft Advertising Agency, Inc.* are all ex-officers of the United States Army Air Service, with both theoretical and practical knowledge in the Aeronautic Field, assuring expert service for clients.

GRANVILLE A. POLLOCK, President of the *Aircraft Advertising Agency, Inc.*, previously to his release from the Army with the rank of Captain, served in the war from its beginning and was a member of the famous "Lafayette Escadrille." In addition to this war aviation service, Captain Pollock is by profession an aeronautical engineer.

S. HERBERT MAPES, Vice-President of the *Aircraft Advertising Agency, Inc.*, is another Air Service Captain who has recently laid aside his uniform after having served in important capacities at various aviation training fields in this country. He is well known as an automobile racer, an exhibitor of saddle horses and a winner of Horse Show Blue ribbons, as well as being a member of many prominent clubs.

REED GRESHAM LANDIS, of Chicago, son of Judge Kenesaw M. Landis, is also a Vice-President of the *Aircraft Advertising Agency, Inc.* Besides having been a Major in the American Air Service, he has the added distinction of being the second ranking American "Ace" with 12 Air Victories to his credit.

WILLIAM MENKEL, Secretary of the *Aircraft Advertising Agency, Inc.*, also served as a Captain in the Air Service, holding various positions at Washington and in the field, including that of Commanding Officer of the Aviation Repair Depot at the Speedway, Indianapolis, Ind. Previously to entering the service, Captain Menkel was for more than 15 years associated with the American Review of Reviews.

The AIRCRAFT ADVERTISING AGENCY, INC. aims to cover the advertising field for aeronautics, including:

DISPLAY ADVERTISING for General Advertisers on Dirigible, Kite, and Spherical Balloons, Aeroplanes, Streamers from Aircraft, and by the dropping of Souvenirs and Handbills from the Air;

PREPARATION of COPY and SKETCHES and the PLACING of ADVERTISING for manufacturers of Aircraft, Accessories, and Aviators' equipment in aircraft and other periodicals.

AERIAL PHOTOGRAPHS of Cities, Summer Resorts, Country Places, Real Estate Developments, Etc.

RATES ON APPLICATION.

The Aircraft Advertising Agency, Inc. is now booking the space for exhibitors at the **Second Pan-American Aeronautic Convention and Exposition at Atlantic City, N. J., May 1 to June 1, 1919,** and also has charge of the preparation of the elaborate souvenir Program, advertising rates for which may be had on application.

The Aircraft Advertising Agency, Inc. also controls advertising space on Aeroplanes, and kite and Spherical Balloons operating from the permanent Aviation Field at Atlantic City, N. J., and on the 36,000 square feet of Bill Board space on the fence of this Aviation Field.

(*Continued from page* 574)

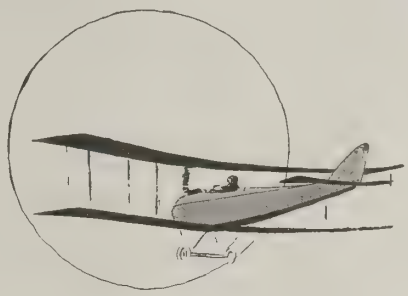
Some of the naval aviators were: Lieut.. (J. G.) Harry E. Adams, Pensacola, Fla.; Ensign Hugh J. Adams, Pittsburgh, Pa.; Ensign Spencer T. Alden, Fort Wayne, Ind.; Ensign Junius F. Andrews, Durham, N. C.; Ensign Edmund B. Barry, Rochester, N. Y.; Ensign Louis Bergen, Long Island City, N. Y.; Ensign Arthur L. Boorse, Birmingham, Ala.; Ensign Milton D. Brice, South Minneapolis, Minn.; Lieut. (J. G.) John S. Buchanan, Boston, Mass.; Ensign Thomas W. M. Draper, Brighton, Md.; Ensign Philip B. Frothingham, Portland, Me.; Ensign Benjamin L. Lee, Jacksonville, Fla.; Ensign Eric Lingard, Annisquam, Mass.; Lieut. Kenneth MacLaish, Blencoe, Ill.; Ensign Allen L. Nichols, St. Paul, Minn.; Ensign Phillip W. Page, Washington, D. C.; Ensign Lloyd A. Perry, Oconomowoc, Wis.; Ensign Stephen Potter, Detroit, Mich.; Ensign Edwin S. Pou, Smithfield, N. C.; Ensign Harold A. Pulliam, Lexington, Ky.; Ensign Curtis S. Reed, New York; Ensign Fred Eries, Aurora, Ill.; Ensign Daune H. Ruttledge, Robelin, La.; Lieut. (J. G.) Arthur Fuller Souther, Cleveland, O.; Ensign Albert D. Sturtevant, Washington, D. C.; Ensign Elmer B. Taylor, Cedar Grove, N. J.; Ensign Hugh Terres, Kensington, London; Ensign M. Terrier, Baltimore, Md.

The aeronautic authorities assembled at Atlantic City for the Pan-American Convention are keeping close touch with the Trans-Atlantic flight and have issued interpretations of the value of the achievements of the Trans-Atlantic fliers, which have been printed the world over.

Scores of technical papers of great value to the aeronautic movement have been presented to the convention, which will be published in future issues of AERIAL AGE.

Great interest has been manifested at the Airport by the arrival of two Sopwith machines. The machines will be piloted by Capt. Mansell R. James, late of the 45th Squadron, R. A. F., and Lieut. Alan L. Clark, 46th Squadron, R. A. F.

They will fly two machines of a type never before seen in America. These are Sopwith Camels, so called because of the hump for the Vickers machine gun mount in front of the pilots seat. The planes, which are owned by the two pilots in partnership with Cecil James, a brother of the Captain, were landed in New York from the Orduna on May 17 and immediately brought here to be made ready for the prize flights.



It is the avowed intention of James and Clark to make their first flight from here to Boston, 350 miles, on a straightaway. They intend to return here the next day, and on the following day to start out for Cleveland and Detroit, winding up at Toronto. In all these cities, cash prizes will reward the best flights from Atlantic City during the month, and the records will count also for the Pulitzer Trophy.

The Sopwith Camel is a very light single-seater, with a wingspread of twenty-nine feet and an overall length of nineteen and one-half. Its power plant is a nine-cylinder Bentley rotary motor, air cooled, rated at 150 to 175 horsepower. The ordinary gasoline capacity is twenty-five gallons, but extra tanks now being installed will double this. The cruising speed is 120 miles an hour, with a maximum of 140.

The Camels had a distinguished war record, having been used by some of the most noted aces. James himself is a war pilot of distinction, having been officially credited with nine Teuton planes on the Italian front. He was downed himself on the Cambrai front, in December, 1917; was in several German prisons, and three times escaped and was recaptured. He is twenty-five and Clark is twenty-one.

James took up one of the Camels for a try-out flight of twenty-five minutes and flew to an altitude of 6,000 feet, passing out of sight of spectators. On the return he raced around the Airport Field, to show the speed of his mount.

"Come along and Fly, you don't need to be afraid, for we will insure you. Don't miss the experience. It will make your trip to Atlantic City worth while."

GREATER DEVELOPMENT OF AMERICAN AERONAUTICS URGED AT ATLANTIC CITY CONVENTION

THE country and the press are applauding the Second Pan-American Aeronautic Convention. For thirty-two consecutive days this convention, with the demonstrations at the Atlantic City Airport, has been educating the country to the marvelous future of American aeronautics, and has aroused interest in aeronautics among the hundreds of thousands of people of different lines of endeavor.

The representatives of thirty-two countries attended the Convention, and they were unanimous in stating that this was the greatest and most constructive convention ever held. The fact that the Convention and Exposition resulted in the sale of not less than 150 aeroplanes is an evidence of the tremendous public interest created. It has given American aeronautics a new start, a veritable flying start.

Urge Greater Aeronautical Development

The convention adopted resolutions urging upon Congress the adoption of a liberal program of the development of aeronautics, including the establishment of engineering schools in every state along the plans of the state agricultural colleges and experiment stations to do for aviation what the latter have done for agriculture.

The resolutions, which received the unanimous endorsement of the Aero Club of America and the Aerial League of America before it was introduced and passed amid much enthusiasm, read:

"Whereas, It is universally conceded that the development of the natural resources of the United States, together with the encouragement of American industries and commerce of all kinds, is one of the most vitally important matters for the consideration of the Special Session of Congress, and

"Whereas, It is obvious that organized engineering and industrial research is one of the most important and necessary factors in such development of our natural resources, industries and commerce, and

"Whereas, The art of flying has been so far developed that the use of flying machines of various kinds has taken a permanent place in the commercial life of the nation as well as in the equipment of the American Army and Navy, and

"Whereas, the art of flying and the devices for flying and minimizing the dangers of flying have only begun to be developed, and need the broadest encouragement, and

"Whereas, The establishing of engineering experiment stations in each state and territory for the promotion of engineering and industrial research as a measure of industrial, commercial and naval progress and preparedness in time of peace or war is one of the most important steps which Congress could take at this time in the encouragement of further progress in the art of flying, and the development of men trained in research along all lines bearing upon the art of flying and the construction of flying equipment, and

"Whereas, There is a bill before the Special Session of Congress, known as the Smith Howard Bill, proposing the establishment of the said engineering experiment station, the work of which includes aeronautics, aerodynamics and many other researches and investigations bearing upon the art of flying and the production of materials needed in the art of flying;

"Therefore, Be It Resolved, That the Second Pan-American Aeronautical Convention, in executive session, Atlantic City, New Jersey, express its unanimous endorsement of this Act by the Congress of the United States in making appropriations for the establishing of the proposed engineering experiment stations, and also the hope of this body that Congress will by this Act give this encouragement to American engineering and industrial research without further delay."

The resolution followed the report presented by Henry Woodhouse.

"The flight of the NC-4 has opened the way for non-stop transatlantic flights," said the report. "But it is evident that to make such voyages it will be necessary to revolutionize aeroplane construction.

"A flier capable of crossing from Atlantic City to Paris, for instance, will have to be three times as large as the NC-4. One of the most important features of the NC type machines is that the lift is thirteen pounds per square foot of wing surface, whereas the maximum lift per square foot of wing surface in aeroplanes heretofore has been only nine pounds to the square foot. These four pounds represent a great gain when it is considered that the NC weighs more than 25,000 pounds. This gain makes it possible to think of building an air liner capable of crossing from Atlantic City to Paris. But such an aeroplane will have to lift a load of over 100,000 pounds, including the commercial load, and therefore it will require not less than 10,000 square feet of wing surface.

"This can be done, although it will require a different arrangement of the wings from that now followed in aeroplane construction. A biplane which would do this would need a wing span of 171 feet and a chord of over 28 feet. But these dimensions are unwieldy, and, anyway, we are not going to stop with a machine that will lift fifty tons.

"The only way to get them is to have more planes or wings. Caproni has done this with his great triplanes. But is there any reason why we should stop with three wings? Why not have four, five, or a dozen? The idea of tandem wings was applied by Professor Langley in his plane many years ago, and therefore it is not new, nor is the idea of multiplanes. But to apply these ideas to the construction of large machines involves solving new problems.

"How are we going to construct a body or fuselage for this multiplane? We must provide spaces for cargo in such locations so as to make them readily accessible and at the same time to make the movement about the center of gravity of the whole machine either comparatively small or else nicely equalized, in order to prevent undesirable flying defects. The problem of fuel storage is also present. The machine would be multi-motored, and the location of these motors and their fuel supply will involve a large amount of careful planning.

"Furthermore, if our plane is to be a passenger carrier, comfortable quarters must be provided. Here again we must try to emulate the standards of yacht and ship builders. We should try to locate our passengers so that they could obtain an unimpaired view, since this is one of the supreme joys of an air voyage.

"The type of multiplanes will also involve problems. If it

is to be a flying-boat type, it must be made strong and seaworthy, and at the same time not unduly heavy. If we are planning a land machine the landing gear must be proportioned to withstand the heavy loads, with a good factor of safety, and yet not offer too much air resistance in flight.

"We recall that the Avron triplane at the Boston-Harvard meet, September, 1910, had the tendency to topple over at the least cause. That established a traditional prejudice against triplanes and quadruplanes. But the height of aeroplanes has gone up, and although the prejudice still remains, the height of aeroplanes is increasing year by year. The Porte triplane is over 27 feet 6 inches high; the Caproni triplane is over 19 feet high; the Gotha-Zeppelin is 21 feet high; the Voisin triplanes 18 to 19 feet high; the Handley Pages are 18 to 20 feet high, and the NC type is 19 feet high.

"But there is a limit to the piling of one plane on top of another for the reason that you soon make the machine so topheavy that it is hard to fly and almost impossible to land without turning a somersault. So we have got to find some other way of arranging our extra wings if we are to have them. If we tried to build a triplane with 10,000 feet of surface it would have to be about 50 feet high, and I shouldn't like to be in it when it tried to land.

"But suppose we make it a quadruplane, and instead of putting our four wings one above the other we put one pair in front and another pair back of them. We can go on adding more wings at will, grouping them in sets so that we can increase the lifting surface beyond anything that is considered possible now and yet without making a topheavy machine. It is up to our aeronautical engineers to work out these problems, and I prophesy that they will do it in the near future.

"Congress should allow the funds necessary for the Army, Navy, and Post Office to conduct the experiments necessary to develop these huge planes. To the Navy these large planes will be regular flying torpedo boats, carrying several full-sized Whitehead torpedoes and going at 100 miles an hour. To the Army it will mean having aeroplanes capable of carrying 3-inch guns, which would be most potential weapons for coast defense and for preventing the landing of enemy forces on American soil; to the Post Office it will mean delivering mail between New York and San Francisco and from the United States to England, France and Italy without stops. It is a most important development which should be supported by Congress. It will bring about commercial transportation by air on a large scale and will solve some of the most difficult problems of transportation."

Aerial Forest Fire Patrol

The aerial timber "cruiser" is the newest commercial development of the aeroplane and the flying boat. Vast tracts in the northwest, rich in mineral deposits and fine timber, are shortly to be placed under the scrutiny of experts through the use of aircraft, contracts for such surveys having already been awarded to the pioneer commercial air line formed for that purpose, according to Lieut. Col. R. B. Girouard, a Canadian engineer-flyer, speaking before the Second Pan-American Aeronautic Congress.

"The possibilities of the flying boat and hydroaeroplane as a means of transprotation into the interior of Canada is becoming more apparent every day. It gives a unique opportunity for the hundreds of trained flyers who received their schooling during the war. The owners of big timber and mineral tracts are recognizing now that the flying machine offers the quickest, easiest and cheapest means of securing the information that will lead to the development of the richest kind of territory.

"Heretofore it has been necessary to send out experts and guides to make these prospecting trips. It was arduous work that entailed great expense and months of travel. But now aircraft are preparing to change all of this. The flying boat and the hydroaeroplane are the logical means of mapping out and investigating the resources of this country, because more than twenty-five per cent of the area is water, and there is good landing always in sight on the rivers and lakes to which the flyer could drop at any time.

"The plan being followed out is to divide the areas up into blocks that are numbered. The cruiser flies to the particular block he wishes to prospect, secures samples of the minerals or timbers and in addition to laying out maps also secures aerial photographs, so that when he returns to the headquarters of the projecting company he is able to show not only the products, but also by actual photographs point out how the stuff is located and point out the best meas of transportation. There is one strip 250 miles long and 30 miles wide that such prospecting is to be carried out on shortly, the contracts having already been signed.

"Reference to the Dominion and Provincial Geological reports will satisfy anybody of the great possibilities of this north country, especially in Northern Quebec and Ungava. Twelve years ago the Ontario Government projected and built the Temiscamingue and Northern Ontario Railway from North Bay to Cochrane, resulting in the opening up of the famous Cobalt Silver area and the Porcupine Gold Fields and the Abitibi Clay Belt were added to agricultural areas of Ontario and timber and pulp wood limits were thrown open to the public for development. These same latitudes produced east into the Province of Quebec are as yet undeveloped. In fact, I might say, unexplored, but the reports brought in by surveyors, geologists and sportsmen all tend to prove that Northern Quebec has at least the same possibilities as Northern Ontario.

"The projection of railroad surveys, the traverse of rivers and lakes by aerial photographs, in fact, the securing of information in detail heretofore impossible to get, except in a very rough and general way—information valuable to the government, the investor and the public at large, is awaiting the aerial pioneer.

"The prospects not only hold good for the timber and minerals, but in the transportation of valuable cargoes of furs and fish. You read only the other day of a Canadian aviator making a trip from the interior of Canada to New Jersey with an aeroplane full of fine pelts."

President Alan R. Hawley, of the Aero Club of America, Secretary Augustus Post, and Mr. Henry Woodhouse greeting Capt. James at the Atlantic City Airport.

Duplex Telephony Demonstrated

First public demonstration of wireless duplex telephony was given before officials of the Convention through a small system installed by experts of the General Electric Company. The instruments, connected up in the Atlantic City Yacht Club, were employed to receive and send telephone messages to the cruiser "Rosemar," anchored in a basin a half mile from the clubhouse, Earl Ovington, an engineering wizard of the Curtiss Company, owner of the boat, collaborating with the other demonstrators. The audience was first permitted to talk and receive at the same time with the same ease with which the modern telephone with wire connections is used. Later a musician was placed aboard the cruiser, and when he played a solo, it was delivered to the audience at the clubhouse through an amplifier.

Mr. Alexanderson, inventor of the new system, described just how the instrument worked. In explaining the new wireless apparatus he said: "Just imagine a man standing a hundred feet away from you, trying to talk to you in a whisper, and then a second man alongside you, with a megaphone, talking at the top of his voice into your ear. You wouldn't have a chance of hearing the whisper. Yet this is just the condition which confronted us when we tackled the problem of duplex wireless telephony.

"As developed during the war, the wireless telephone made it necessary to have a switch and throw from receiving to transmitting in order to operate. In other words, when a man wanted to talk on the wireless telephone he would throw a switch, say to the left, and that would operate the transmitter. When he wanted to receive the spoken word from the other station he would throw the switch to the right and that would throw in the receiver. But he could not receive a message and talk at the same time as you can on an ordinary telephone. When you receive and talk at the same time,

that is called 'duplex.' In the case of the wire telephone it is a comparatively simple matter, as you can lead the currents along the wires, but with the wireless 'phone the current comes through the ether of space, and the powerful transmitting current swamps out the delicate receiving current, so that the two cannot operate under ordinary conditions.

"In duplexing by wireless, powerful transmitting currents go out from the station, and at the same time the delicate receiving currents come in. The problem is to so adjust things that the receiving instrument is dead to the transmitting currents which go out from its own station, but receives the signals from the distant stations. And as its own signals are, of course, right next to it, they are very much more powerful. In other words, the most powerful signals must be blotted out, or counteracted, and the delicate signals from the

Lieut. Alan Clark and Capt. M. R. James, the Sopwith pilots at the Atlantic City Airport

distant station received. And that is the problem which confronted the wireless telephone experts, and that is the problem which they solved."

Sopwith Demonstrations

Lieut. Alan Clark, late of the Royal Air Force, thrilled throngs with the stunts he performed with a Sopwith "Camel" scout machine, tearing through space at 130 miles an hour as one of the final tests of different type machines for commercial adaptability of the Second Pan-American Aeronautical Convention. The machine, which was immediately dubbed the "flitter," skidded through the atmosphere with such terrific speed that the operator was able to stand it directly on its wing tips in a vertical position in making banks and on the straightaway it showed twice the speed of other machines hovering over the field.

The Sopwith climbed 5,000 feet into the air in a twinkling, and then Lieut. Clark put it into a tail slip with its nose pointed straight up. The machine spun around like a giant top for a full minute, then dipped suddenly into a nose spin for a 2,000-foot gimlet toward earth, from which level it was permitted to go through all the stunts that made such wonderful records for the scouter on the Italian and French fronts.

Parachute Demonstrations

The convention held the final tests last week for the mail delivery system from an aeroplane with the use of "petite" parachutes, each capable of carrying the weight of 1,000 letters, more than would be the average delivery at any one community along an aerial mail route. The aeroplane of Eddie Stinson was hitting it up at 70 miles an hour when Lieut. Jean Ors, inventor of the parachute, released six parachutes in a row at second intervals. They clustered after their release and deposited 25-pound bags of sand within a radius of 18 feet on the field. Government officials are to be brought here next week to witness the parachute mail tests with the idea of securing their adoption for the sky mail routes. With their adoption it is certain, officials declared, that the delivery of mail will be greatly expedited, because the aeroplane mail express will be able to continue its flight without slowing up.

There were further demonstrations of aerial life preservers, the Watkins and Ors type parachutes being used with great success in dropping out passengers from varying altitudes to a safe landing on the field. George Weiss, of Pittsburgh, a former navy balloonist, tested out the Watkins chute while Warner Genot, a Belgian, leaped from speeding aeroplanes with the Ors chute.

Because the students at the big colleges were busy with their final examinations, it was necessary to postpone the Intercollegiate Aeroplane Contests. They will be renewed the last Saturday in June, and be continued each Saturday for the balance of the summer. Yale, Harvard, Dartmouth, Pennsylvania, Princeton, Colorado, Columbia, Amherst, California and Tufts are to battle it out for the supremacy of the air during the summer here, both over land and sea, in the land and seaplanes.

Constructive Service to Aeronautics

A remarkable case of devotion to the aeronautic movement was revealed at the Second Pan-American Aeronautic League of America's Diploma of Honor to Mrs. A. S. Abell, of Baltimore and her five sons, two daughters and her daughter-in-law.

Every one of the following nine members of the Abell family are members of the Aerial League of America: Mrs. Arunah Shepardson Abell, Mr. Arunah Shepardson Abell, 3rd, Miss Margaret Anna Abell, Mr. Edwin Franklin Abell, 2nd, and Mrs. Abell, Mr. Walter William Abell, 2nd, Mr. George William Abell, Mr. Robert Louis Abell, Miss Marie Louise Abell.

The five sons are also members of the Aero Club of America.

The oldest member of the family, Mr. A. S. Abell, 3rd, is 26 years old; the youngest member is Miss Marie L. Abell, who is only 16 years old.

The entire Abell family, which is well known through its being connected with the Baltimore "Sun," has followed aeronautics for the past ten years, every member being interested in it, and they all came to Atlantic City for the Second Pan-American Aeronautic Convention and Exposition, where they have stayed for the entire convention.

As there are to be conducted extensive scientific contests and demonstrations of the application of aircraft for different purposes, Mrs. Abell held a family council, and the family unanimously decided to live in Atlantic City for the summer, and they took a large residence only a few hundred feet from the Atlantic City Airport, which was christened "Pilot's Port and Aeronautic Arcadia."

Mr. A. S. Abell, 3rd, the oldest son, has presented a trophy, to be competed for annually in races between Atlantic City and Baltimore.

The trophy was presented through the Aero Club of America and Aerial League of America, who will draw the rules for the competition.

Throughout the war the Abell family has participated in, and supported in many ways the progressive work of the Aero Club of America and the Aerial League of America, which contributed so extensively to the building of the American Air Forces, and assisting American Airmen in many ways.

Rear-Admiral Robert E. Peary, the President of the Aerial League of America, was to present the Diploma of Honor to the Abell family, but his illness prevented his coming to Atlantic City from Washington. In sending his regrets he stated that Mrs. Abell and her five sons and two daughters and daughter-in-law have set an example which American families ought to follow at this crucial time in the history of American aeronautics, when, unless the American public supports the aeronautic movement in every way possible, America will again fall behind other countries in this marvelous field of human endeavor.

Mr. Alan R. Hawley, the President of the Aero Club of America, who took the place of Admiral Peary in making the presentation, stated that the devotion of the Abell family to aeronautics has been one of the most inspiring factors to him and other active workers in the Aero Club of America and Aerial League of America.

Aerial Photographic Bombardment

The resort's beachfront was "shot up" by an automatic camera gun that "mowed down" promenaders along the Boardwalk with the same precision and rapidity of a machine gun. Mounted with a swivel arrangement on the cowl of a Curtiss seaplane, the camera, an invention of E. C. Bass, of New York, registered "bull's-eyes" up to 5,000 feet when operated by Mr. Bass.

The camera has many of the characteristics of a regular machine gun, being sighted as quickly and by the same methods and operated by a trigger that pumps the "shots" over at the rate of the fire of the best machine guns. The shots were made singly and in bursts, the shutter continuing to operate continuously while the finger was on the trigger or making a lone picture on "sniping" shots.

The Bass camera gun is a day-light loading device, making

it possible for the "gunner" to snip off any part of the moving picture film used in the bright sunlight without ruining the film. It has a capacity of 100 feet of film with room for 1,600 pictures, and while the photographs are not moving pictures, they are taken in much the same manner, following one after another along the line of the film.

The camera itself is removable from the gun so that the latter may be left on the mounting and is sufficiently adaptable to be used in any position. Every picture automatically registers on a timer and number, so that the operator always knows the exact number of pictures he has taken and the time each snap was made.

Mr. Bass originally designed the device to be used in training machine gunners, the wonderful accuracy made possible by the "hits" registered being used very successfully by the French aerial machine gunners. With a number of changes it has now been perfected for commercial purposes and will be employed for surveys and general topographical work, for aerial police work as well as improving the marksmanship of flyers. An Aerial duel will be fought later in the week between operators in two seaplanes over the ocean. By the timing device connected up with the trigger it will be possible for the judges to discover which "gunner" "killed" the other first as well as reproducing pictures that will show the number of bull's-eyes made.

Mr. Bass also demonstrated a "moviette," a small, compact moving picture camera measuring eight inches long, five and one-half inches wide and three inches through. Many of the principles employed in the camera gun are used, but instead of a trigger a handle is used to flash the shutter, turned like that of the ordinary movie camera. This little camera, weighing but three and one-half pounds, was taken aloft over the Atlantic City Airport and its developed films were sharper in detail than any taken thus far from an aeroplane during the Pan-American Aeronautic Convention. Because of its light weight and small measurements, the operator had great freedom of movement, and the demonstration won high praise from notable experts.

Sporting gunnery contests will be held with the camera gun later, the records of marksmanship being submitted to a competent board of judges. Every effort will be made to introduce this sport among the colleges as a means of creating a most valuable reserve of aerial expert gunners ready for any sort of an emergency.

Contest Winners

The Contest Committee of the Second Pan-American Aeronautic Congress in its report announced the winners of the various contests staged in connection with the annual convention here throughout the month of May. Awards will be made on June 5th. The following results were given out:

Opening Day, Seaplane Race—E. K. Jaquith, Atlantic City to New York; passenger, Harold Willets; time, 1 hour and 45 minutes; first prize, $500; Curtiss F-boat. B. H. Kendrick, Atlantic City to Perth Amboy; passenger, E. L. Reed; time, 2 hours; second prize, $250; Curtiss F-boat.

Opening Day, Land Plane Race—Roland Rohlf, Westbury, L. I., to Atlantic City; passenger, Victor Hugo Barranco; time, 2 hours and 8 minutes; first prize, $500; Curtiss Oriole. Edward Stinson, Queens, L. I., to Atlantic City; passenger, Lieutenant G. W. Shaw; time, 2 hours and 33 minutes; second prize, $250; Curtiss JN-4.

Intercollegiate Seaplane Race, May 3d—Pennsylvania, S. R. Beckwith, first prize, $250; Columbia, Ensign W. S. Martin, second prize, $150; Yale, Ensign A. A. Beckwith, third prize, $100; Amherst, Augustus Post, fourth prize, $50.

Intercollegiate Land Plane Race, May 3d—Columbia, Lieutenant A. L. Smith, first prize, $250; Yale, Ensign A. A. Beckwith, second prize, $150; Columbia, Lieutenant G. S. Lennstrand, third prize, $100.

Intercollegiate Land Plane Race, May 24th—Princeton, Lieutenant Jack Frost, first prize, $250; Pennsylvania, Lieutenant C. H. Payne, second prize, $150; Columbia, Lieutenant Floyd Gahman, $100; Yale, Ensign A. A. Beckwith, $50.

Boston Globe Trophy—Captain Mansell R. James, R. A. F., first prize, $1,000; M. W. Hodgdon, Boston, second prize, $500; Frank H. Stanton, Princeton, third prize, $250.

Herald Efficiency Prizes—Captain Mansell R. James, R. A. F., first prize, $1,000 (Class B, aeroplane with more than 100 horsepower); A. Livingstone Allen, second prize, $250 (Class A, under 100 horsepower).

Aerial Commuting—Greatest Total Distance During Month—Frank H. Stanton, Princeton, 920 miles; Robert Shank, Atlantic City, 796 miles; A. L. Allen, New York, 236 miles.

Greatest Number of Trips—Frank H. Stanton, Princeton, 6 trips; Robert Shank, Atlantic City, 5 trips; A. L. Allen, New York, 1 trip.

Longest Flights—Captain Mansell R. James, R. A. F., 340 miles; Frank H. Stanton, Princeton, 340 miles; A. L. Allen, New York, 340 miles.

Note—Where the same distance was covered the awards were based on the time. The prizes awarded were the Second Pan-American gold, silver and bronze medals.

Pulitzer Trophy, Valued at $5,000—Captain M. R. James, R. A. F., Atlantic City to Boston; elapsed time, 4 hours, one stop of 40 minutes at Mitchell Field, L. I.; run made May 26th.

Parachute Contest—$500 Bennett Prize—Lieutenant Jean Ors, three trials, two by Werner Genet from 350 and 1,000 foot levels; W. L. Watkins, three trials, jumps by George Weiss, same altitudes; Lawrence Sperry, two trials, jumps by F. Godwin from 1,000 foot levels. Decision on winner deferred pending compilation of records.

Urge Adoption of Medical Standards

The adoption of International Medical Standards for the classification of those who want to fly was urged in a report rendered to the Second Pan-American Aeronautic Convention by the Special Committee on Air Medical Standards.

The report discloses the fact that recommendations were made for International Air Medical Standards two months ago by the Joint Committee on Air Medical Standards of the Pan-American Convention and sent to the Inter-Allied Aeronautic Commission in Paris, which is forming the rules and regulations to govern international aerial navigation.

The report presented points out that while a great majority of people can fly to heights of over 15,000 feet, there are a sufficient number of people who cannot fly to heights above 10,000 feet to make it necessary to classify flying aspirants in accordance to the heights to which they can fly.

The work of classifying people in accordance to the altitude level to which they can fly must be done by specialists who are the equivalent of the "flight surgeons" which were created in the U. S. Air Medical Service of the United States Army eighteen months ago, and save hundreds of lives of Army aviation students as well as aviators at the front.

The need of "flight surgeons" to deal with the medical aspects of civilians as well as military aviators was emphasized in the report rendered by the committee. The report disclosed for the first time, how the Air Medical Service classified 30,000 Army aviators according to the heights to which they could fly, and how "flight surgeons" kept the aviators in good physical conditions throughout the war. The report urges the establishing of "flight surgeons" as a permanent body of experts to look after the civilian aviators, pointing out that the "flight surgeon" is entirely an American institution created in the beginning of 1918.

The report gives credit for the good work performed to Brigadier-General Theodore C. Lyster, U. S. Medical Service; Lieut. Colonel Isaac H. Jones, Colonel George H. Crabtree, Colonel Eugene R. Lewis, Colonel Nelson Capen and Mr. Walter Camp. For this pioneer work General Lyster was awarded the Distinguished Service Medal.

Aeronautic Maps

"The map of the future is the air mosaic," declared Lieutenant M. C. Lawrence, R.M.A., A.S.A., speaking before the convention. "Whether it be the military map, the automobile road map or a map of the air routes, the only absolutely accurate information of the terrain, the roads, the elevation of the towns, cities and all topographic features, is the minute mosaic—the map produced by dovetailing pictures snapped from the aeroplane of any given territory. The Government, realizing the value of these records of the country, has already started to employ the aviators still in the training camps of the West in making of a map that is expected to cover every inch of territory in the United States.

"The making of this map is a stupendous undertaking and will probably require years of hard work and application, but its military and commercial value once it is completed will be unlimited.

"It has been said that the eye, the sextant, planes and all other mechanical measuring devices can be fooled, but the sensitive vision of the isochromatic plate cannot be fooled. Photography played a most important part in the war. The observer was easily misled by camouflage of the enemy, but to date there has never been perfected a camouflage that can fool the eye of the camera. Gun emplacements most carefully concealed were readily revealed on the plates of the camera. Every slight change in the ground was depicted by the camera, and now the work of picturing every bit of this country has really been started by the Government, and

The News of the Week

$25,000 Offered for New York-Paris Flight

A prize of $25,000 has been offered by Raymond Orteig for the first non-stop aeroplane flight between New York and Paris, a distance of about 3,600 miles. That distance has never been flown by an aeroplane without stopping.

Mr. Orteig is proprietor of the Hotels Brevoort and Lafayette. He said to-day that he was led to take an interest in flying by talking with American and French airmen, who have visited him at the Brevoort.

"These men believe that the next five years will bring great development in the aeroplane," said Mr. Orteig. "It was their enthusiasm that converted me. Then I was seized with the idea of combining sport with the art of flying. I was born in France, you see, and I have lived in this country since 1882. So I decided that a New York-Paris flight would be a big thing, both toward the future of aviation and to further unite the two great nations.

"My only stipulation was that the airmen making the flight must be of allied nationality. The other details will be announced as soon as I have them. The Aero Club of American is preparing a set of rules for my approval concerning the conditions under which the flight must be made. The start may be made from either side."

U. S. to Get 1,600 Foreign Planes

Washington, D. C., May 30.—One thousand Nieuport and 600 Spad aeroplanes, and 1,000 Hispano-Suiza and 800 Gnome motors will be shipped to the United States under the terms of an agreement between the French Government and the United States Liquidation Commission.

The planes and motors represent a part of the aviation equipment contracts for abroad by the War Department.

Recommendation to Abandon Naval Program Not to Apply to Aircraft

Washington, D. C.—Although Secretary of the Navy Daniels has recommended the abandonment of the naval three-year building program in order to demonstrate confidence in the League of Nations, he urges the granting of the $45,000,000 appropriation for aviation. "If this appropriation is made," he said, "we intend to spend very little in stations The entire amount, so far as practicable, will be used in experiments. We wish more planes for our ships to be used in fleet manoeuvres. They are absolutely necessary to effective manoeuvres."

St. Petersburg to Havana in 5 Hours 20 Minutes

Havana, Cuba.—Flying a Curtiss F boat, Johnny Green made a flight from St. Petersburg, Fla., to Havana, Cuba, a distance of 381 miles, in 5 hours and 20 minutes, averaging over 70 miles an hour. This is the first commercial flight between Cuba and America.

First Woman Makes Air Journey From Washington

The first woman to make the air journey from Washington to New York, the Army Air Service announced, is Mrs. E. E. Harmon, wife of an army lieutenant, who left Washington at 11.10 A. M. to-day and arrived at Hazelhurst Field two hours and forty-five minutes later. Her husband piloted the machine, a military bombing plane, and Colonel Robert E. O'Brien, Colonel William C. Sherman and Major Raycroft Walsh were other passengers.

Cuba Thanks U. S. Air Service for Instructors

Washington, D. C., June 2.—A letter was received from the Cuban Minister through the Office of the Secretary of State by the Office of the Secretary of War which expresses the appreciation of Cuba of Kelly Field and School of Military Aeronautics, Austin, Tex., for the efficiency, devotion and the interest manifested by the corps of instructors of the School of Military Aeronautics of Austin, Tex., and of the United States Aviation School, Kelly Field, San Antonio, in the training of the group of aviators and machinists of the Aviation Corps of the Cuban Army, who were sent to those schools for their instruction.

To Preach From Pulpit 2,000 Feet Up in Air

The first sermon from the air, preached by a "sky pilot" of the Methodist Church, will be a headliner at the Methodist Centenary Exposition, to be held at Columbus, Ohio, June 20 to July 14, according to plans announced.

According to the exposition's press agent the aerial sermon will be preached by a minister who will float above the heads of his congregation at a height of 2,000 feet or so. His message will be audible to all by means of a wireless telephone and a megaphone attachment.

Aerial Police Patrol Proposed for Detroit

Detroit, Mich.—Control of air traffic in Detroit by a flying patrol is classed by the police commissioner as not only a possibility but a probability. The commissioner expressed himself strongly in favor of an auxiliary to the police department for aerial work and an effort will be made at once to interest prominent Detroiters in the matter of purchasing aeroplanes for the police department.

Aero Club of Columbia Will Purchase Landing Field

New York, N. Y.—Lieut. E. L. Smith, president of the Aero Club of Columbia, announced that the organization will soon be flying its own planes on its own field in the near future. Contributions for the purchase of planes and gifts of equipment have been generously given. A. Monell, director of the International Nickel Corporation, and J. P. Grace of W. R. Grace, with contributions of $1,000 and $500, respectively, being among the recent donors.

The club has 24 flying members, some of whom have seen service overseas. Conspicuous among these are George De Forrest Larner, American ace; Lieut. M. D. Lowenstein, who was attached to the 49th Bombing Squadron, and Lieut. A. K. Doolittle.

Dean George B. Pegram said recently that he is looking forward to the time when courses in aeronautics will be established as part of the curriculum of the School of Engineering.

End 3,300-Mile Flight From Texas to Pacific

Washington, May 27.—The War Department was notified to-day that the Ellington Field "Gulf-to-Pacific" squadron

Lieut. Ormer Locklear, the Aerial Acrobat, Performing for the Benefit of the Crowds at Atlantic City's Airport

of DeHaviland Four planes has just returned home after a remarkable cross-country flight of 3,300 miles from Texas to the Pacific Coast and return.

This squadron, under command of First Lieut. R. O. Searle, charted unknown territory, skimmed the waters of the Gulf of Mexico, darted over the backbone of the continent at a height of 16,000 feet, tasted salt water at San Diego, and has even flown 600 feet underground.

Accompanying Lieut. Searle on the flight were Lieuts. E. D. Jones, Rick Nelson, Charles Rugh, Howard Birkett and E. L. Bilheimer, Sergeant W. E. Cain and Louis Lewyn, a motion picture photographer.

The actual flying time for the 3,300 miles traversed was 1,940 minutes. This is an average speed of about 101 miles an hour.

Remarkable spurts of speed were made at times. On the way from Kingman, Ariz., to Tucson, Ariz., flying at an altitude of 14,000 feet, Lieuts. Eearle and Jones passed over Phoenix, Ariz., which is 167 miles distant from Kingman, in exactly one hour after they had left the latter place.

The trip from San Diego to Los Angeles, a distance of 134 miles, was accomplished in fifty-six minutes, an average speed of about 140 miles an hour.

Lieuts. Searle and Jones made the first trip ever attempted across the Grand Canyon in an aeroplane. They crossed the big chasm at the junction of Diamond Creek and the Colorado River Canon, which, at this point, is about 2,000 feet across, with a sheer drop of 7,000 feet. They flew at an altitude of 13,000 feet, and were bothered by terrific bumps and cross currents of air. The ship was knocked around and buffeted so that it was hard to control it.

Lieut. Rugh and Lewyn, the motion-picture man, actually flew down into the canyon. They got down to 600 feet below the edge of the canyon.

First Flight Into Yosemite Valley Made

Yosemite, Cal., May 27.—The first aeroplane flight into Yosemite Valley was accomplished on May 27 by First Lieutenant James Stephen Krull, flight commander at Mather Field, flying from Merced, Cal.

Rising to an altitude of 11,000 feet, Lieutenant Krull completed the eighty-mile flight into the heart of the Sierra Nevada Mountains in one hour and five minutes.

Oil Companies Use Aeroplanes to Deliver Pay Rolls

Several Texas oil companies have adopted aerial delivery for their pay-rolls, the increase of speed and the safety from possibility of hold-up being among the considerations that led to the adoption of aeroplane delivery.

Bernard H. Baker, Mayor of South St. Paul, Minn., reports the successful use of an aeroplane in campaigning for office.

A Brooklyn physician has purchased an aeroplane to use in flying from his home to Lake George, where his summer bungalow is located.

Sioux City to Establish Landing Field

Sioux City, Ia.—The Sioux City Chamber of Commerce and the local Press Club are conducting a campaign for the establishment of a local landing field.

Impetus to the movement was given by a visit of Captain Eddie Rickenbacker and an elaborate banquet tendered by the Press Club of Sioux City. It was at Sioux City Speedway that Captain Rickenbacker in 1914 won his greatest dirt track race.

Underground Dirigible Hangar to Reduce Construction Expense

As a solution of the difficulty of constructing dirigible hangars suitable for housing eight or more dirigibles and permitting launching under the most favorable conditions regardless of wind direction, a writer in a German publication suggests the use of a large circular trench. A light metal roof having doors is to be operated by a motor so that any airship, particularly the one most favorably located as to wind direction, may be launched. The cost of construction of a hangar system of this type is said to be lower than for buildings where the high strength required on account of wind, coupled with difficulties of launching encountered in adverse winds are serious disadvantages.

Admiral Peary, Explorer and the President of Aerial League of America, Elected to Board of Managers, National Geographical Society

Washington, D. C., June 2.—Rear Admiral Robert E. Peary, U. S. N., retired, Arctic explorer and discoverer of the North Pole, president Aerial League of America and member of the Board of Governors of the Aero Club of America, was elected to be a member of the Board of Managers of the National Geographic Society to succeed the late Brig. General John M. Wilson, U. S. A., who died recently.

San Francisco-Los Angeles Passenger Service Planned

San Francisco, Cal., May 28.—Plans for the development of aero routes on the Pacific Coast were given out by the Pacific Aero Club at its annual meeting in this city, these plans including a cross-continent flight from San Francisco to New York, and a mail and passenger route between San Francisco and Los Angeles.

A private company is just completing plans for the aero passenger service between San Francisco and Los Angeles, according to Frederick Porter, first vice-president of the Pacific Aero Club, and assurances have been given that the government will co-operate with the private undertaking in establishing an air mail service between these two points.

The types of planes to be used in the mail and passenger service will be the Glenn-Martin bombers, equipped with two 400-horsepower Liberty motors, which will carry 10 passengers, and Handley Page machines which carry 20 passengers. Passengers' compartments on these machines will be completely inclosed. Landing stations for this service have already been purchased or leased at Stockton, Fresno, and Bakersfield, by the Pacific Aero Club.

Aviation Will Be Discussed at Commercial Conference

Washington, May 31.—Aviation as an aid to Pan-American commerce will be one of the features on the program of the Second Pan-American Commercial Conference to be held here June 3 to 6. The possibility of this latest method of transportation in the development of trade between the United States and Latin America, is one of the topics whih will be discussed by the commercial experts who will be present at the gathering. Plans are being considered for a special exhibition flight over the Washington Monument grounds adjoining the Pan-American Building for the benefit of the conference on the day aviation transportation is under discussion. Shipping and transportation, financing trade and the future of Latin American investments, loans and bonds, trading methods for exports and imports, parcel post, patents and trade marks, trade and travel regulations, engineering, educational aids to commerce, these and other phases of commercial intercourse will be taken up by experts in the various lines. Telegrams have been sent by Director General Barrett of the Pan-American Union to the Governors requesting them to send representatives who will report back to the business interests of the States on the possibilities of future trade relations with Latin America. The United States and every other republic of North and South America will be represented at the conference.

DEPARTMENT STORE INAUGURATES AEROPLANE DELIVERY SERVICE

DOES Newark know how? Apparently it does.

The first regular aerial "store to customer" delivery service in the country was inaugurated May 25 between L. S. Plaut & Co. and Asbury Park.

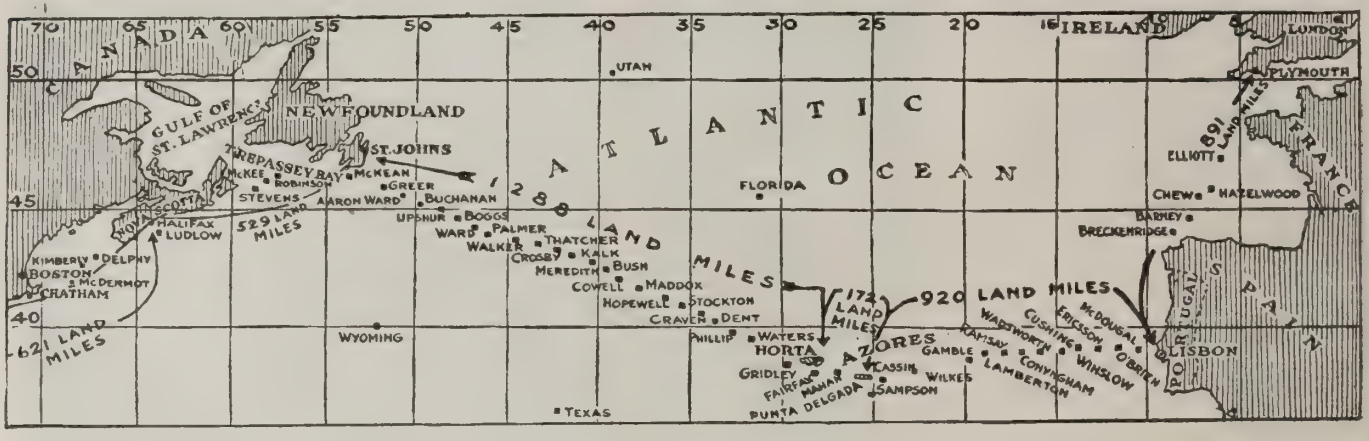
The plane, specially designed and constructed by the Witteman-Lewis Aircraft Co., which was piloted by Lieutenant Paul Micelli, who was accompanied by Lieutenant Louis Goldberg, both of whom had formerly been in the United States Army Serice as pilots and instructors, made the flight between Newark and Asbury Park in approximately 25 minutes, flying time.

Starting from the aviation field on Lincoln Highway, the plane first flew over the central part of Newark, making several manœuvres over and around Plaut's, very much to the admiration of thousands of spectators who crowded the streets below. The plane then set a straight course for Asbury and in spite of the rain-storm that had set in and low hanging clouds which obscured the pilot's vision, made a wonderful trip to Asbury, landing on the aviation field there in perfect order. Plaut's auto trucks were awaiting the arrival of the plane and within a few minutes the merchandise was transferred to the trucks and the mail bag was delivered to the Asbury Park Post Office within six minutes of the plane's arrival.

The plane carried in addition to its customers' parcels, a mail bag and the two pilots. The pilots were sworn in at the Newark Post Office as postal messengers so as to give them legal status to carry the mail from Newark to Asbury. This is the first time in history that a commercial organization was authorized by the Post Office Department to carry mail, which is an unusual honor and compliment paid to the Plaut Co., and evidence of the great interest taken by the Government in aeronautical developments.

A letter from Mayor Gillen to Mayor Clarence E. F. Hettrick of Asbury Park, carried in the mail bag, follows:

The aviator who will deliver this letter to you will bring you greetings from the people of Newark.



As I understand it, for the first time in the history of the world an aerial delivery service for the transportation of merchandise is established. The aeroplane which carries our greetings to you will hereafter transport daily merchandise for the progressive and enterprising business house of L. S. Plaut & Co. of this city, between Newark and Asbury Park.

This is a remarkable advancement in aerial navigation. Our respective municipalities are to be congratulated for taking such a foremost position in the field of progress.

Mr. Chester A. Brown, advertising manager of the L. S. Plaut Company, with Julius M. Meirick, a promoter of commercial aviation, had full charge of arrangements for the flight. They will announce a regular schedule in the near future, Mr. Meirick declared.

Personnel of L. S. Plaut & Co., and Wittemann-Lewis Aircraft Co., who co-operated in establishing the first store-to-customer department store aerial delivery

THE TRANS-ATLANTIC FLIGHT SUCCESSFULLY COMPLETED

WHEN Lieutenant-Commander Read brought the American seaplane NC-4 to her anchorage in Lisbon harbor he had achieved the triumph every flying man of every nation had dreamed of—passage between the New World and the Old World by an aircraft. Germans had planned such a trip in their mighty Zeppelins; Hawker and Grieve had boldly challenged the perils of an unescorted dash; French aviators had laid their plans for a well-considered attempt to the south. It was on May 27 that Read and his crew won the imperishable fame their victory over mechanical difficulties, the elements and the weakness of the human organism confers on them.

But theirs was no adventure of sportsmanship. They were under orders in the naval service of their country, and their goal was not merely the coast of Europe. They were instructed to fly by a definite route to a particular objective. Had they not reached that objective their trip would destination of the seaplane flight. But no other spot could have been more appropriate have been unsuccessful from the official point of view. Consequently their labors did not cease until their craft came to rest in the English harbor of Plymouth.

As the Navy is not sentimental in the ordering of its cruises, practical reasons dictated the selection of Plymouth as the ate for the ultimate landing place of a pioneer transatlantic airship sailing from the United States. From Plymouth the Mayflower Pilgrims departed September 6, 1620, to make their homes in the New World, to found "a church without a bishop, a state without a king."

The conquering of the air in the flight over the Atlantic was only one of the problems the Navy set out to solve when it began the experiments that brought forth the NC flying boats. The situation produced by Germany's submarine war made it desirable that a new method of combating U-boats should be devised. Our naval authorities looked to the development of the aeroplane to provide it. Their intention was to produce a machine capable of crossing the ocean in the air, of alighting on the water and making progress as a boat, of rising from the sea. The performances of the three seaplanes that departed from Rockaway May 8 have justified the design that was adopted. The NC-4 was able to overcome mechanical difficulties and complete her trip; Commander Towers's flying boat, after being forced to the water, carried its crew in safety to Ponta Delgada; and Lieutenant-Commander Bellinger and his crew were saved when their boat was compelled to quit the air. From the mishaps of these aviator-sailors, no less than from the experiences of the NC-4 and her complement of men, the Navy Air Service will learn wherein the plans and specifications of the NC class should be modified. Thus all have contributed to the future of the art of flying.

Mastery of the air will belong to America if the United States will exert itself to hold and maintain it. The new profession of flying is American by virtue of the discoveries and application of scientific principles made in this country.

The NC-4 the first aircraft to successfully cross the Atlantic

Crew of the successful NC-4, from left to right: Lieut. Commander A. C. Read, commander; Lieut. E. F. Stone, pilot; Lieut (j g) Walter Hinton, pilot; Ensign Rodd, radio operator; Chief Special Mechanic E. H. Howard, engineer; Lieut. J. L. Breese, reserve pilot engineer

Our leadership was lost to us by our own lethargy and indifference. Read and his fellows, the opportunity having been given to them by an awakened officialdom, have restored it to us.

The last "hop" of the American Navy's ocean-spanning plane, the NC-4, was completed May 31, when Lieutenant-Commander Albert Cushing Read flew the giant machine into the harbor of Plymouth, England. This last leg of the long-dreamed-of transatlantic flight was from Ferrol, Spain, and was accomplished without untoward incident, the flight requiring just one minute less than seven hours.

Secretary Daniels announced that no further instructions had been sent as to the movements of Commander Read and his crew. The question as to whether the historic plane will be flown back to the United States by a more direct route or knocked down and shipped back, has been decided by circumstance. The flight across was planned on the known fact that except for about four days a year the wind would be in the direction of the flight and the engines of the big plane were designed for seventy hours' continuous service. The terrific strain to which they have been subjected since this one successful unit of the fleet of three flying boats left Rockaway and the fact that a head wind of at least ten miles an hour would have to be fought against all the way back, will make it necessary to ship the flying boat back to the United States.

Immediately upon receipt of the news of Read's successful landing Secretary Daniels sent the following message to the naval aviator:

"All the people of America are happy over your successful flight, which has been an epoch making event in the history of the world. My congratulations and greetings and good wishes."

Receipt also was announced of the following message through Rear Admiral Knapp from the British Admiralty:

"This morning's news brings the epoch making intelligence that the space between America and Europe has now been successfully spanned by air by way of the Azores. It is with great pleasure that their lordships have heard of this success and they desire me to offer their congratulations to the crew of the seaplane NC-4 and to the United States Naval Air Service on the fine achievement."

Flew 4,514 Miles

The hop to England from Portugal came really as an anti-climax. Read's great feat had been accomplished when he brought his giant plane to rest in the harbor of Lisbon. The bridging of the Atlantic by air was then an accomplished fact and the 775-mile flight to Plymouth was taken for granted as certain of accomplishment from the moment the success of the transocean flight was flashed back to America.

Crew of the N.C-1 from left to right: Lieutenant-Commander P. N. L. Bellinger, commander; Lieut.-Commander M. A. Mitscher, pilot; Lieut. J. T. Barin, pilot; Lieut (j. g.) Harry Sodenwater, radio operator; Chief Machinist's Mate, C. I. Kessler, engineer; Machinist Rasmus Christensen, reserve pilot engineer

In this last leap in the long flight the troubles which have followed Read and the NC-4 since the beginning of the flight cropped up again. He was forced to bring his plane down twice, the last time at Ferrol, Spain, in order to complete the scheduled trip to Plymouth.

From first to last the NC-4 has been taken 4,514 miles—ordinary land miles—or 3,923 knots or nautical miles, on the following schedule:

Schedule of NC-4's Eventful Flight From Rockaway

Course.	Date.	Distance, Knots.	Time.	Speed, Knots.
Rockaway-Chatham, (forced landing about 100 miles off Chatham)	May 8	300	5:45	52
Chatham-Halifax	May 14	320	3:51	85
Halifax-Trepassey	May 15	460	6:20	72.6
Trepassey-Horta	May 16-17	1,200	15:18	78.4
Horta-Ponta Delgada	May 20	150	1:45	86.7
Ponta Delgada-Lisbon	May 27	800	9:44	82.1
Lisbon - Mondego River	May 30	100	2:07	48.8
Mondego River-Ferrol	May 30	220	4:37	45.6
Ferrol-Plymouth	May 31	455	6:59	64.8

The crew of the NC-3 from left to right: Lieut.-Commander John H. Towers, commander; Lieut.-Commander H. C. Richardson, pilot, Lieut. David McCullough, pilot; Lieut-Commander H. A. Lavender, radio operator; Machinist, L. R. Moore, engineer; Lieut. (j. g.) Braxton Rhodes, reserve pilot engineer

© International Film The NC-4 arriving at the Azores, after successfully flying the longest span of the Trans-Atlantic journey

The flight across the Atlantic from Newfoundland to Lisbon, a distance of 2,150 nautical or 2,472 land miles, was made by the NC-4 at the rate of 80 knots, or 92 miles per hour. This is far in excess of the cruising speed of 63 knots, announced at the start of the flight.

When the NC-4 reached Plymouth, her destination, she had traveled a distance of 3,925 nautical, or 4,514 land miles.

Commander A. C. Read belongs to the second group, in point of time, in the development of Annapolis graduates in aviation. To the first group belonged Towers, Richardson, and Bellinger. The pioneers became pilots through individual training. Read is a member of the first aviation class of the navy, that of 1914. He had been graduated at the Naval Academy earlier, near the top of his class, and his ability advanced him rapidly in aviation. He not only won a place as one of the best pilots, but also as an administrator in the aviation division.

Commander Read was born in New Hampshire in 1887, and appointed a midshipman from Massachusetts in 1903. He is married and has one child, a boy. He is a small man, quiet and observing.

There is perhaps no naval aviation officer who has put more conscientious study and effort into flying than has Lieutenant Commander Read. He has devoted his time to it since 1915, and in these four years has proved his worth as a pilot and as an administrator.

© Press Illustrating

Lieut.-Commander A. C. Read, who will go down in history as the first air pilot to successfully trans-navigate the Atlantic

His first sea service after he was graduated was on board the battle ships Massachusetts, Indiana and Arkansas. In November, 1908, he was ordered to report for duty to the commander of the Third Squadron, Pacific fleet, and was assigned to duty on board the destroyer Decatur. He was ordered home in August, 1911, and left Nagasaki harbor on September 11. Two days later he was promoted to the rank of lieutenant, junior grade. He was made a lieutenant, senior grade, on July 1, 1913.

After he reached home he was assigned to duty at the torpedo station at Newport. From this post he was sent to Pensacola to study flying. He remained there a year and then was ordered to duty aboard the cruiser North Carolina and later to the Washington. On June 5, 1917, he was detached from sea duty and sent to the aviation station at Bay Shore, L. I., of which he became commander.

Lieutenant Commander Read has a wife and child. He married Miss Bessie Burdinie, of Miami, Fla., on January 31, 1918.

First Lieutenant Elmer F. Stone, pilot and constructor, belongs to the United States Coast Guard, and is one of the oldest fliers in that organization. His skill and daring when the war placed a greater pressure on the Navy led to his transfer to the Bureau of Construction and Repair as a test pilot for new machines, and the record he made won him a place in the transatlantic list. Lieutenant Stone was born in New York in 1887, and appointed to the United States Coast Guard Academy from Norfolk, Va., from which he was graduated in 1910.

Lieutenant Walter Hinton, pilot, was an enlisted man who became an ensign in March, 1918, and on account of his skill as an aviator was designated as one of the pilots of the flying boat H-16 in its flight from Rockaway Beach to Hampton Roads last January. Hinton was born in Ohio and is 31 years old.

Ensign Herbert C. Rodd, radio officer for No. 4, assisted in the development of the radio compass used on the three seaplanes. Before he joined the United States Naval reserves in August, 1918, Ensign Rodd served as radio operator on the Great Lakes. He was born in Cleveland, Ohio, in 1894.

Congratulations From Secretary Daniels

Official word of the arrival of the seaplane at Lisbon reached the Navy Department first through a dispatch from Brest, France, sent by Rear Admiral Halstead, commander of the American Naval Forces in French waters. The message was received at the Otter Cliffs, Maine, station and relayed to Washington.

Immediately Secretary Daniels cabled the congratulations of the department to Lieutenant Commander Read. The Secretary also sent a cable message to President Wilson at Paris telling him that American naval aviators had been the first to cross the Atlantic.

The message to Lieutenant Commander Read follows:—

"Lieutenant Commander Albert C. Read,
"Commanding NC-4 seaplane,
"Care Rear-Admiral Plunkett,
"U. S. S. Rochester, Lisbon, Portugal:

"The entire navy congratulates you and your fellow aviators on your epochal flight. The ocean has been spanned through the air and to the American navy goes the honor of making the first transatlantic flight. We are all intensely proud of your achievements and thankful that it has been accomplished without mishap to any one of the daring aviators who left our shores on the first air journey to Europe. To all of them and to you all honor is due.

"JOSEPHUS DANIELS."

The cable message from the Secretary to President Wilson said:—

"Know you will be delighted to learn naval aviators first to cross Atlantic."

Secretary Daniels explained that the first Atlantic trip was the beginning of a series of experiments in long distance flying and that very probably, after defects in naval aircraft brought to light during this flight had been corrected, an other squadron of seaplanes would be headed across the Atlantic. Mr. Daniels said he has not decided whether the NC-4 should attempt to fly back to the United States or be "knocked down" at Plymouth and shipped back to America.

The Vickers "Vimy-Rolls" biplane which is being set up at St. Johns for a Trans-Atlantic attempt

Invaluable Data for Future Flying Gathered

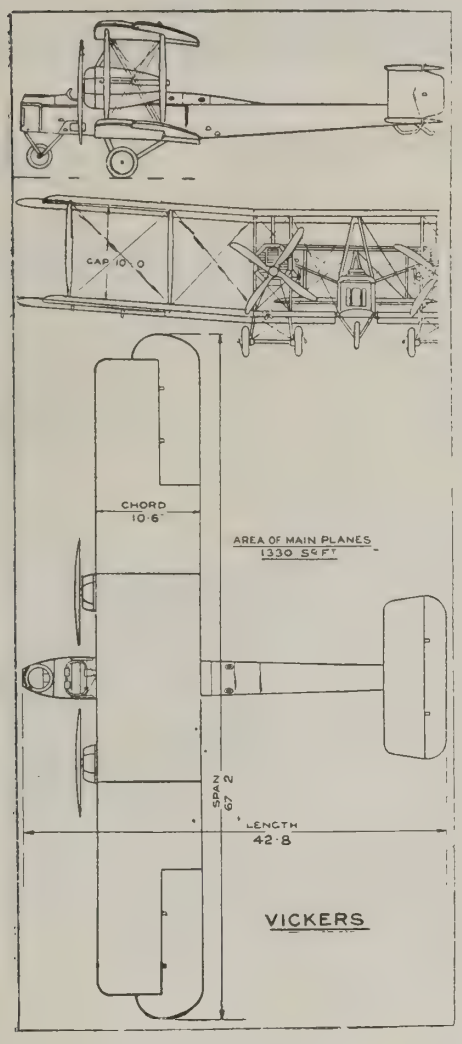
Naval officers who have been in close touch with the American transatlantic flight believe very important practical lessons may be drawn from it which will bring the time when such flights are everyday affairs perceptibly nearer.

In the first place it is learned that they are very well satisfied with the proof of the practicability of navigating aeroplanes by the stars. All three of the American fliers succeeded in keeping on their course to the Azores, and though the chain of destroyers was of advantage as an insurance against accidents, as a matter of fact the planes could have been navigated without their aid.

This, of course, means that transatlantic pilots must have a seaman's training, and even the highly skilled ordinary aviator like Hawker needed a sailor like Grieves to keep him straight.

Secondly, the value of station ships as meteorological observatories has been clearly demonstrated. Up to the present, weather forecasts for the mid-Atlantic have been almost valueless through the lack of means to record storms which do not happen to hit any of the regular land stations.

The experience of this flight shows that this difficulty could easily be surmounted by having a very few vessels cruising in definite areas and sending regular reports to a meteorological headquarters ashore.



Third, much gratification is expressed at the way the planes that came down stood their Atlantic buffeting. Commander Towers's NC-3 rode out waves thirty feet high, and although he could not make a rising, stood the test all right.

Certain modifications will be made as the result of his experience, and it is confidently hoped that much more seaworthy planes soon will be evolved.

Finally, it is evident that still larger planes must be developed in order to carry bigger stocks of gasoline so as to provide a greater margin of fuel.

When the fog difficulty was suggested to a naval authority he replied that it could be overcome by the development of direction finding by radio which has already been worked out for large craft, but is not yet sufficiently perfected for so small a vessel as an aeroplane.

It is also pointed out that, quite apart from the safeguards they provided for the crews of the naval fliers, the destroy-

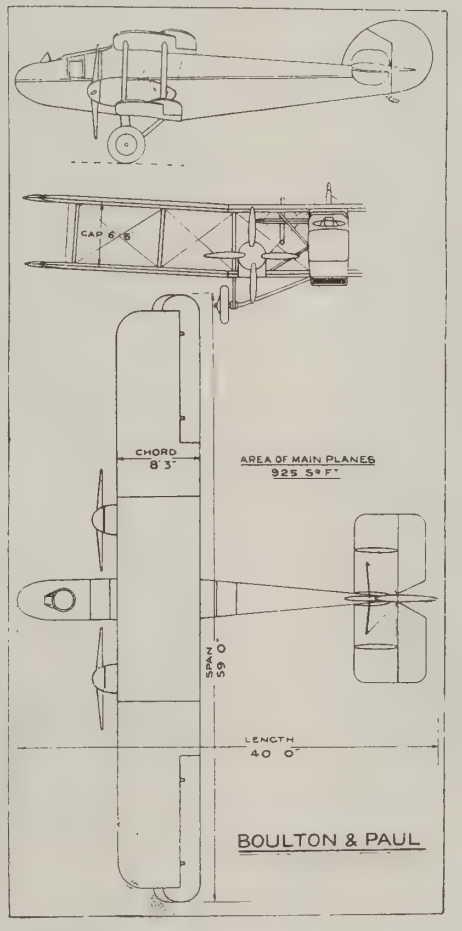
ers played a very important part in the great experiment. It has been possible, by their means, to test the value of a number of different kinds of wireless equipment, and many useful results will be gathered from their experience.

The Vickers Entry

The Vickers craft is being assembled at St. John's on the field at Mount Pearl, where Hawker and Grieve took off. It carries two standard Rolls-Royce engines of 350 horsepower each. The gasolene tanks have been increased to make a capacity of 865 gallons. This, in the opinion of Captain J. Alcock, her pilot, will permit the Vickers-Vimy to fly 2,440 miles without alighting. While the maximum speed is more than 100 miles an hour the engines have been throttled down to an average speed of ninety miles for the overseas flight.

The wing span of the Vickers-Vimy is only 67 feet from tip to tip. Nevertheless it is a sturdy craft, huge in construction. Its body is 42 feet 8 inches in length. The wings are 10 feet 6 inches in width.

A wireless set is being installed as part of the finding apparatus. Its range both for receiving and sending is about 250 miles.



Captain Alcock, the pilot, was born in Manchester in 1892 and received his technical training at the Empress Motor Works in Manchester. He became interested in aviation in its early days, and has been a pilot since 1912. In the famous London to Manchester race in 1913 he won second place.

He became an instructor in the Naval Flying Corps at the outbreak of the war, and later was chief instructor of Britain's "acrobatic squadron." As commander of a bombing squadron in long-distance raids over Turkey he won the Distinguished Service Order.

One night he was compelled to land on enemy soil owing to engine trouble, and was taken prisoner by the Turks. He remained a prisoner until the end of the war.

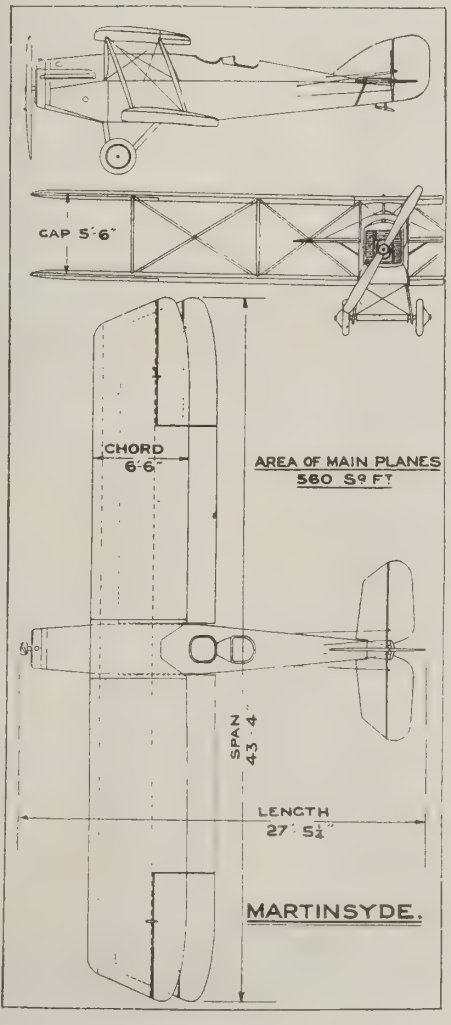
Lieut. Arthur W. Brown, navigator of the Vickers craft, was born in Glasgow in 1886. His parents were Americans. He received his technical training with the British Westinghouse Company, and due to his expert knowledge of surveying became a specialist in aerial navigation.

He served with the Second Battalion of the Manchester Regiment in France in the early days of the war and later became

an observer in the Royal Flying Corps. He was also taken prisoner over the western front in 1915, and remained interned in Switzerland until the end of the war.

The Handley Page Entry

Like the Vickers machine, the Handley Page bomber was intended for bombing Berlin. She could then carry 1,190 gallons of gasolene, a 200 pound wireless set, 6,640 pounds of bombs, twelve machine guns weighing 557 pounds and a crew of seven men.



She made 90 miles an hour on her test flight with this load. The machine is being slightly changed, however. Her gas capacity will be about 2,366 gallons, giving her a possible flight duration of 22 hours without stopping. This would give her approximately three hours' leeway in making the Irish coast, with ordinary weather conditions and no adverse winds.

The transatlantic crew will consist of four men, pilot, navigator, wireless operator and observation officer. The pilot will be Major H. G. Brackley, D. S. O., D. S. C. He is 24 years old, and when the war broke out was a student just beginning the journalistic course maintained by Reuters, the great English news syndicate. He volunteered for the war and reecived his pilot's certificate in 1915. He had his first flying in the Shortt machine, and participated in the first night bombing of Bruges and Zeebrugge. He received his Distinguished Service Order for his services in these raids.

His first command was the Seventh Naval Squadron; he was later assigned to the Fourteenth Army Squadron, and later when the Royal Air Force was organized he was made a squadron commander. Under him he had many Americans, some of them pilots.

His navigator will be Major Tryggve Gran, a Norwegian, 30 years old. While a lieutenant in the Norwegian army he flew from Cruden Bay, Aberdeenshire, to Norway, carrying a copy of the "Daily Mail" to Queen Maud. He was the first pilot to complete successfully the North Sea flight. He served as a ski expert with

THE RADIO TELEPHONE EQUIPMENT OF THE NC-4

By EDGAR H. FELIX, A., I. R. E.
Formerly Radio Engineer, Signal Corps, U. S. A.

THE radio telephone transmitting set used on the NC-1, NC-3 and NC-4 is known by the type number S.E. 1,100, the letters S.E. indicating it to be a design of the Bureau of Steam Engineering of the Navy Department. This equipment is also standard on the HS-16 flying boats. The development of this advanced transmitter is the work of the Marconi Wireless Telegraph Company of America.

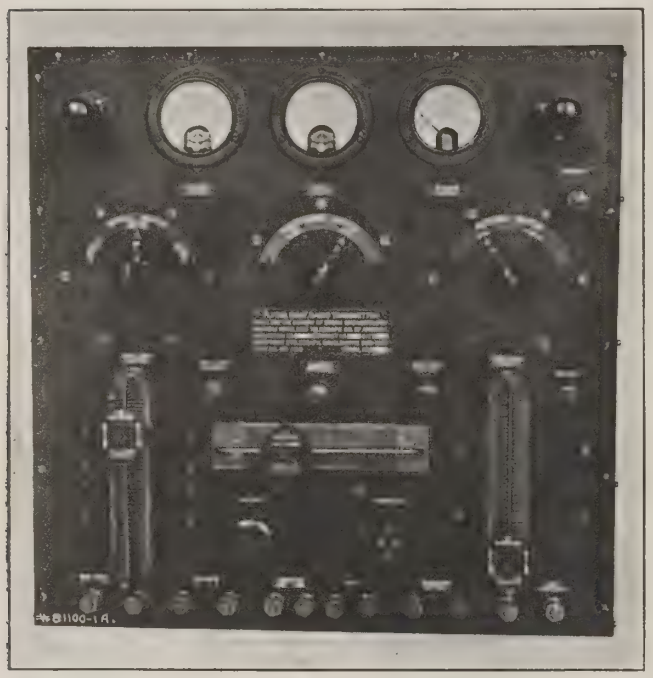

Fig. 1—Front view of the SE 1100 transmitter, showing control switches and rheostats

In preliminary tests off Hampton Roads, this set has transmitted speech over a distance of 150 miles from a seaplane in flight, using a 600-foot trailing antenna radiating a maximum antenna current of 2.5 amperes. In addition to the trailing antenna, the NC boats are also equipped with fixed emergency antennae, stretched above the main planes, to permit transmission while taxying or floating on the surface of the water.

The design of the set permits of transmission of three types:

(1) Voice currents.
(2) Continuous or undamped waves.
(3) Damped waves of audio frequency.

Two wave lengths are used, 1,600 meters being radiated when a trailing antenna 600 feet in length, having a capacity of .0004 microfarads is employed; the other of 600 meters being obtained with the fixed emergency antenna, having a capacity of .00026 microfarads.

Two large pliotron tubes, requiring a filament potential of 18 volts and a plate potential of 1,100 volts are used. One tube is a modulator, which imposes the variations of the voice on the output of the second tube, the oscillator.

The Transmitting Circuit

Following the simplified circuit of the set in Figure 2, we find that the modulating circuit consists of the microphone M, 5-volt battery B and telephone induction coil primary, P_1. By means of the switch, buzzer B may be substituted for the microphone for the transmission of damped waves.

The voice or buzzer modulated current energizes the secondary, S_1 of the telephone induction coil. One end of this coil is connected to the grid of the modulating tube; the other end to the negative side of the filament, through battery B_2 and ammeter A_4. The battery maintains the grid at a negative potential, the critical value of which is obtained by means of a rheostat. When the grid is at negative potential, no flow of current from the grid to the filament is possible.

The potential variations imposed on the grid by the microphone through the transformer are magnified by the modulator tube. The output of this tube is impressed on the oscillator tube, from its plate and negative filament connection to the plate and the negative side of the filament of the oscillator tube, by means of audio frequency transformer L-3. The plates of both tubes are maintained at a potential of 1,100 volts with respect to the filaments by means of 1,500-volt generator G. The choke coil L_4 prevents the radio frequency currents developed by the oscillator tube from flowing back through the generator. Protective condenser C_7 is connected across the brushes of the generator.

In order that a tube may generate continuous waves, it is necessary to couple the grid and plate circuits, either inductively, conductively or electrostatically. The theory of operation of vacuum tubes will not be touched upon here, it having been described in an article by the author appearing in the May 5 issue of this publication.

In this set, the coupling between the grid and plate circuit is obtained inductively through coils L_1 and L_2. The plate circuit consists of plate P, protective condenser C_5, wave length change switch, condenser C_3, which is connected to the negative side of the oscillator filament. The grid circuit consists of grid G, grid condenser C_8, shunted by grid leak R, the grid, by this means being maintained at a negative potential. From the grid condenser, the circuit continues through the wave length changing switch, inductance L_2 and then to the negative side of the filament through condenser C_4.

When it is desired to emit continuous waves, contact K_1 is closed, thus making the circuit regenerative.

The antenna and ground connection is taken off coil L_1, the radiated output being measured by ammeter A_2. Condenser C_2 compensates in the grid circuit for the capacity in the plate circuit due to the antenna and ground.

Operation of Set

Figure 4 shows in greater detail the circuits employed and the arrangement of switches for operation. In order to simplify the diagram, the three main control switches, which may be seen across the center of operating panel in Figure 1, are shown in two parts, the upper and lower portions of the diagram being combined in one switch unit.

There are three positions for the signal switch at the left of the panel. In the first position, continuous waves are emitted. In this position the connections made in the second and third positions are opened. The second position is for telephony; the inside portion of the switch (the upper part in the figure), connects the microphone to the battery, and the

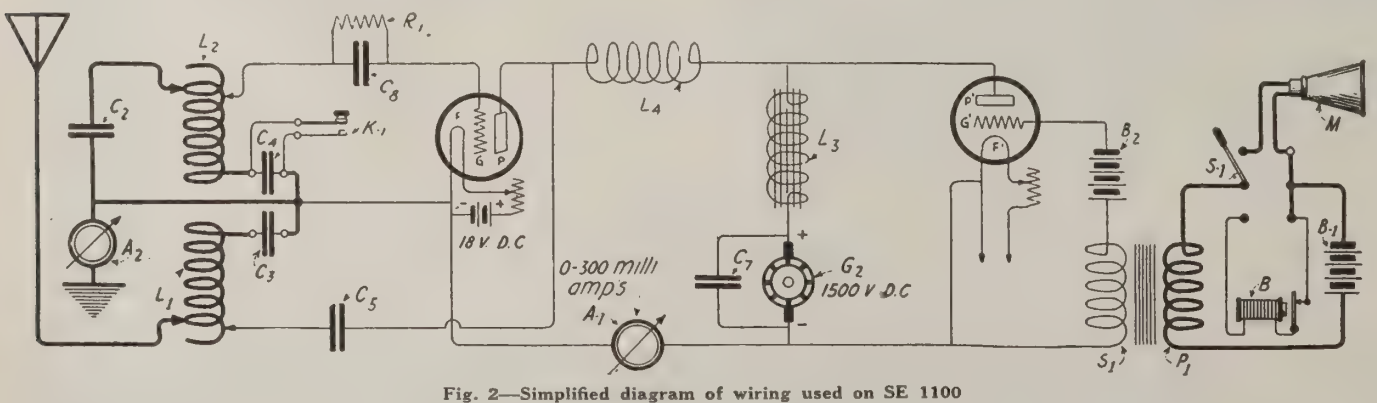

Fig. 2—Simplified diagram of wiring used on SE 1100

outside portion (in the lower part of the figure), completes the filament circuit for the modulating valve and short circuits contact K_1. In the third position of the switches, damped waves are obtained, the buzzer being substituted for the microphone in the connections.

The center switch changes the antenna connections and provides for the two wave lengths, 600 and 1,600 meters.

The antenna switch, at the right of the panel, changes the

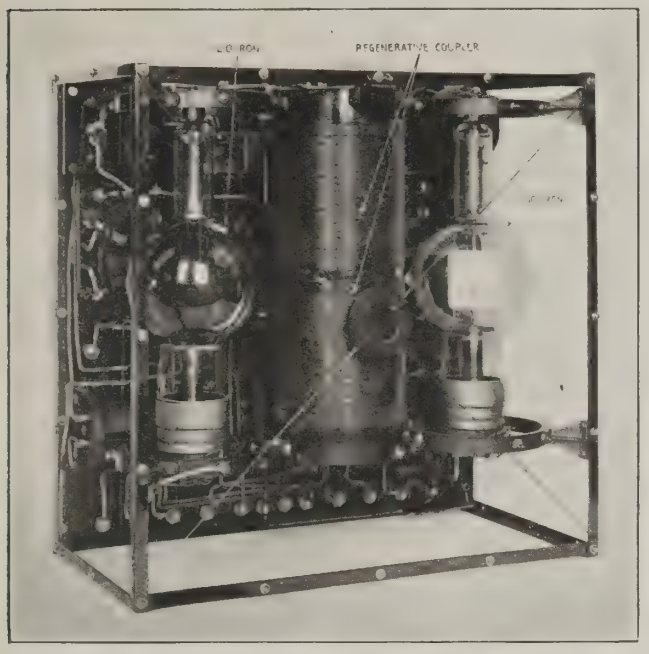

Fig. 3—Rear view of the wireless telephone transmitter showing method of mounting bulbs

set from sending to receiving. At the send position, it completes the 1,100-D.C. supply to the plates of both tubes, and also the connections to the microphone and buzzer.

A direct-current ammeter, A_4 is connected in series with both filaments and reads the total current taken by both of them. The instrument's scale registers from zero to 10 amperes; to read the current in either filament it is merely necessary to cut out the other one. This may be done by means of two small switches marked on the set "oscillator filament" and "modulator filament."

The principal indication for checking up the proper operating conditions of the set is the plate current drawn by each of the tubes from the dynamotor, which is obtained from plate current ammeter A_3, reading from zero to 300 milliamperes.

Three rheostats, mounted on the lower portion of the operating panel control, respectively, the temperature of the oscillator tube filament, the potential of the grid of the modulator tube, and the temperature of the modulator tube.

Constructional Details

The entire set is wired with No. 12 B. & S. gage soft copper wire with empire cloth tubing slipped over it as insulation. No terminal lugs are used; the ends of the wires being in the shape of an eye, which fits the stud terminals and is passed around it in a direction that tends to make the wire grip the stud when the nut is tightened.

The wiring has been so located that small or disturbing capacities between wires are avoided.

Owing to the vibration of the aeroplane, every possible precaution has been taken to prevent the fastenings working loose. Special steel lock washers are used throughout the set. The general scheme of construction is such that the main supports and fastenings will bend before they break, wood or any material which splits or fractures having been eliminated. The steel wire cross braces shown in the illustration make the structure an extremely light and surprisingly rigid unit.

The primary source of energy is two 12-volt, 50-ampere hour batteries. The filaments of the two pliotrons are operated through a rheostat. The 1,500-volt D.C. generator for the plate potential is driven by the 24-volt battery. Three small batteries are required; one for the microphone, another for the negative grid potential and the third for the receiving equipment.

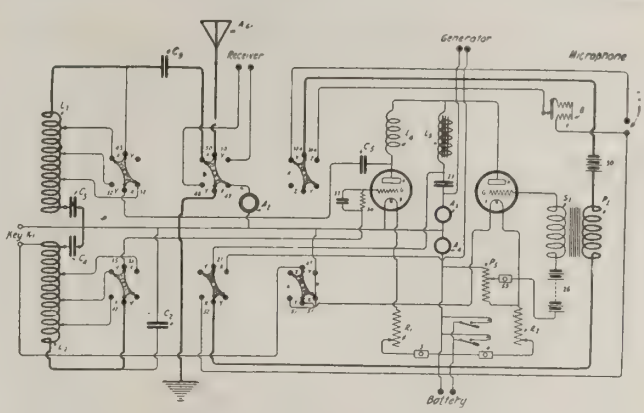

Fig. 4—Diagram showing the arrangement and wiring of the control switches

The Support of the Pliotrons

To insure against breakage, the best position for the pliotrons is vertical, with the large neck at the bottom. This brings the plate terminal cap at the top and the filament and grid terminal cap at the bottom. In each of the two dilecto rings shown at the top of the photograph, three spiral springs placed 120 degrees apart support a spring cap which fits over the plate terminal cap of the pliotrons. The springs are held by small machine screws which pass through the insulating ring. One of these serves as a terminal, being connected by a pig-tail to the spring tap. In each of the two bottom dilecto rings, three spiral springs, placed 120 degrees apart support a special jack block made to take the filament and grid terminals. This block is made in two halves, upper and lower, held together by screws; clamping these spring jacks between them, three posts, which project from the bottom of the jack block, take the ends of the three supporting springs, and are electrically connected by a copper pig-tail to the screw-eyes that hold the other end of the spring to the dilecto ring. The two filament terminals of the tube and the grid terminal are brought out to the three screws in the dilecto ring. Thus, each pliotron is supported to the rigid frame of the set by 6 springs which are set so that when the tube is in place the top springs pull down and the bottom springs pull up.

The mechanical period of vibration of the vacuum tubes in this spring mounting is considerably below that of any vibration that will occur in the seaplane itself. Sudden shocks in any but a horizontal direction are not transmitted through these springs with sufficient violence to injure the tubes.

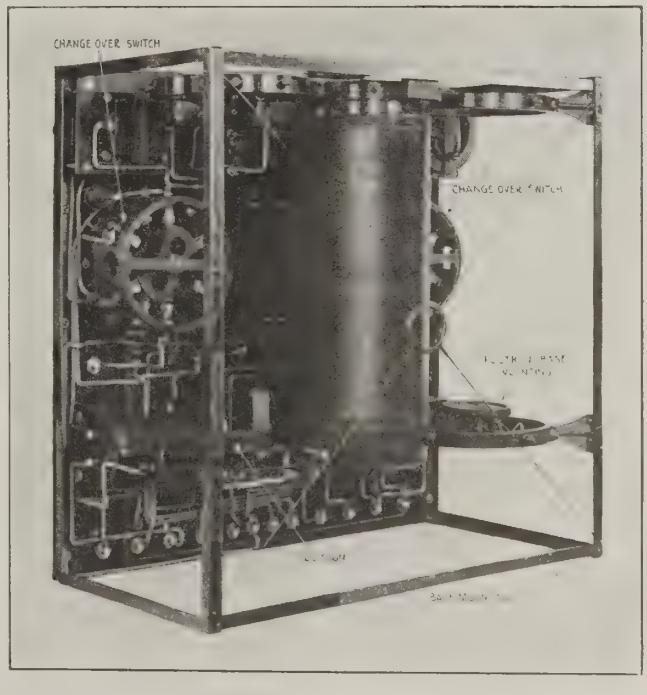

Fig. 5—Rear view with bulbs removed to show the excellent switch construction

THE PROPERTIES OF BALSA WOOD

By R. C. CARPENTER, M. Am. Soc. C. E.

BALSA wood grows extensively in the Central American and northern South American States as a second-growth tree. It is the lightest wood known, so far as any evidence attainable is concerned. This paper shows the microscopical structure and also gives various tests of its transverse and compressive strength. The material is composed of very thin-walled cells, which are barrel-shaped, interlace with each other, and are almost devoid of woody fiber. These cells are filled with air, making a natural structure well adapted to prevent the transmission of heat, because of the particles of air imprisoned in the material without interconnecting fibers.

Balsa wood has been used quite extensively in the past as a buoyancy product for life preservers and in connection with the fenders of life-boats and rafts. Its life is short, under ordinary conditions, unless treated with antiseptic or preservative material. There is promise that it will have a field of usefulness, in the lines referred to, which must make it of considerable interest to the engineer who requires either insulating material or buoyancy products. It is also used for streamlining on aeroplanes in places where strength is not of prime importance.

Very little information is available respecting the wood of the balsa tree. The wood which grows in the Isthmus of Panama is remarkable: first, as to its lightness; second, as to its microscopical structure; third, as to the absence of woody fiber; fourth, as to its elastic character, in the sense of recovery from transverse deformation; and fifty, for its insulation qualities for heat. It is the lightest wood commercially useful, so far as the writer has been able to ascertain, and it has considerable structural strength, which makes it suitable for a fairly extensive use.

The Weight of Balsa Wood

Balsa wood, when thoroughly dried, has a specific gravity of 0.11. For reference, Table 1 shows the relative weights of various woods. Until recently, Missouri cork wood, weighing 18.1 lb. per cu. ft., was supposed to be the lighest, but recent investigations indicate that balsa wood is much lighter having a weight of 7.3 lb. per cu. ft. The ordinary commercial balsa wood is seldom perfectly dry, and, because of the moisture content, its weight, as appears from a number of investigations made by the writer, will usually be between

TABLE 1.—Weights of Woods.

Common name.	Scientific name.	Weight, in pounds per cubic foot.
Balsa	*Ochroma lagopus*	7.3
Cork	(Bark from cork oak, *Quercus suber*)	13.7
Missouri corkwood	*Leitneria floridana*	18.1
White pine	*Pinus strobus*	23.7
Catalpa	*Catalpa speciosa*	26.2
Cypress	*Taxodium distichum*	28.0
Douglas fir	*Pseudotsuga mucronata*	32.4
Sycamore	*Platanus occidentalis*	35.5
Red oak	*Quercus rubra*	40.5
Maple	*Acer saccharum*	43.0
Long-leaf pine	*Pinus palustris*	43.6
Mahogany	*Swietenia mahogoni*	45.0
Locust	*Robinia pseudo acacia*	45.5
White oak	*Quercus alba*	46.8
Hickory	*Carya alba*	54.2
Live oak	*Quercus virginiana*	60.5
Ironbark	*Eucalyptus leucoxylon*	70.5
Lignum-vitæ	*Guaiacum sanctum*	71.0
Ebony	*Diospyros*	73.6
Black ironwood	*Krugiodendron ferreum*	81.0

8 and 13 lb. per cu. ft. As will be seen from Table 1, however, it is much lighter than cork.

Cellular Structure of Balsa Wood

The cellular structure of balsa wood, as exhibited under a microscope, differs from that of any other wood known to the writer. All engineers know that wood is made up of a series of interlacing cellular bodies of microscopic size which, when joined together, form fibers which extend both radially and longitudinally. These cellular fibers are interlaced, and, by their form and arrangement, give the wood its strength and physical properties. In ordinary woods the thickness of the walls of the cells is generally a considerable proportion of the diameter. The cells which are parallel to the axis of the tree are made up principally of woody fiber; those which extend in a radial direction usually have a cellulose structure with little woody fiber, and are defined as "medullary rays," or pith cells, because of their position and composition. The microscopic structure of all the woods involves, in addition, the existence of ducts or vessels scattered through the wood in a longitudinal direction; these serve as a circulatory system for the transmission of liquids and gases during the growth of the tree.

Gross Characteristics

In general appearance, balsa wood resembles basswood. Its medullary or pith rays are uniformly spaced, and are quite prominent in both the radial and cross-sections. In the radial sections they appear much as in maple or sycamore, as well as basswood, but lack the hardness and susceptibility to polish possessed by these woods. The ducts, pores or vessels are large and remote from each other and occur singly or in groups in the strands between the pith rays.

The lightness of the wood is one of its most striking features. This is due to the thinness of the walls of the elements. There is rather indistinct evidence of annual rings

TABLE 2.—Transverse Tests of Balsa Wood.

No.	Dimensions, in inches.	Modulus of rupture.	Deflection, in inches.	Quality.	Where made.

Average weight of Nos. 1–5.....13.2 " " " "

in the cross-section. In the specimens studied, the regular concentric rings, so characteristic of trees of temperate regions, do not show.

Minute Structure

The pith, or medullary ray cells have normal position and form, but the cells are not elongated radially to so great an extent as is usually found in woods. The ducts are large, with rather thin, pitted walls Woody fibers of the ordinary sort seem to be absent in this wood, their place being taken by a cellulose tissue very much like the thin-walled tissue of the pith and cortex of ordinary trees.

The cells making up this tissue are barrel-shaped, whereas woody fibers are taper-pointed and relatively much longer. The most remarkable thing about them, however, is their exceedingly thin, unlignified walls. A section of the tissue in question, examined under a microscope, would not be taken for wood, but rather thin-walled cells or "parmchyma" from the pith or cortex of a stem. The only lignified part is the wall of the duct, and that is relatively weak.

Conclusions

1.—The gross structure of balsa wood is in appearance like basswood, poplar or willow.

2.—Its weight shows that it is fundamentally different from these.

3.—Its minute anatomy is radically different from any wood known to the writer.

4.—What correspond to the woody fibers are not lignified. They are very thin-walled and soft.

5.—The ducts or pores are weakly lignified and are pitted. They, however, constitute a very small proportion of the wood.

6.—The pith rays are also thin-walled and not lignified.

The Strength of Balsa Wood

Table 2 shows tests made under the writer's direction at Sibley College, Ithaca, N. Y., and also as reported by Professor Walter S. Leland, formerly of the Massachusetts Institute of Technology.

Crushing and Compression Tests*

Three specimens, each 1¾ by 2½ by 4 in., with a cross-section of 4.375 sq. in. gave an average of 2,488 lb. per sq. in. Another test of three specimens gave an average of 2,225 lb. per sq. in.

Three specimens, 1 by 1 by 3 in., crushed with loads of 2,210, 2,380, and 2,530 lb. per sq. in., respectively.

Two compression tests, of specimens 1 by 1 by 16 in., showed maximum loads of 1,860 and 1, 980 lb., and net compression of 0.69 and 0.55 in., respectively.

One specimen, 5⅞ by 5⅞ by 23 25/32 in., crushed under a load of 40,900 lb., equivalent to 2,500 lb. per sq. in.; and one slightly smaller gave substantially the same strength per unit of section as reported by Professor Leland in Table 2.

Professor Leland states:

"The crushing strength seems to be very satisfactory for such wood—about one-half the strength of white pine or spruce.

"These tests show the modulus of rupture to be approxi-

mately one-half that of good spruce, and their uniformity clearly shows that the material may be relied on both for direct compression and transverse loads.

"It is very elastic material, and when the load was almost at the breaking point, the load on three of the beams was removed and the beams resumed their original shape.

"It is exceedingly interesting to note that it is practically impossible to split the wood by driving nails through it."

A balsa wood plank supported on horses, the plank being 5½ in. wide, 1¾ in. thick, and 10 ft. 8 in. between supports, carried two men. The weights carried were 187 and 200 lb., respectively. The maximum deflection at the center was about 10 in.

The Habitat

In a recent trip to the Isthmus of Panama the writer found balsa trees growing commonly in all the cleared spaces which were not under cultivation in the Canal Zone. Most of these trees were of small diameter, and evidently quite young, and in every instance they were found in the newly started jungle which has recently been allowed to grow over a goodly part of the Canal Zone since the canal has been completed. In some cases these trees were growing vigorously in the masses of material sliding into the canal. The tree is characterized by a large leaf, from 14 to 30 in. in greatest length, and by the peculiar seed pods which it bears when it reaches a larger size. Excellent evidence was obtained that the balsa tree grows very rapidly, and attains a diameter of from 12 to 14 in. at an age of 4 or 5 years. Rear-Admiral H. H. Rousseau, M. Am. Soc. C. E., now in charge of considerable construction work in the Canal Zone, told the writer that a balsa tree which was growing near his house at Culebra attained dimensions approximating 12 to 14 in. in diameter and from 40 to 60 ft. in height, in about 4 years. A considerable quantity of balsa of large size is to be found near the cleared plantations along the Chagres River, and in various other places near the Atlantic Coast and the banana plantations.

The result of an investigation of the forests of a number of tropical countries, by Mr. Herbert Paschke, undertaken for Capt. A. P. Lundin, indicates that balsa trees are found in considerable quantities in Honduras, Costa Rica, Colombia and Jamaica, and there is abundant evidence that it grows vigorously in most of the tropical countries of South America. The report referred to indicates that the balsa or *ochroma* is entirely a second-growth wood, and is never found in the virgin forest, except as an isolated tree or two where clearing has occurred. The writer also learned, from his visit to the tropics, that forests composed of any one species do not exist in tropical countries, as they are found in the United States. Tropical trees always grow individually or by themselves, and very rarely in close proximity to other trees of the same species. This fact makes it necessary to spend considerable sums for transportation in gathering any tropical timber, as great distances through the jungle have to be traversed in order to obtain the timber of a single tree.

Paneled Balsa Wood	Spruce
4700 lbs. per sq. in.	5000 lbs per. sq. in.

Paneling increases the weight of Balsa Wood about 15 per cent.

WEIGHT AND STRENGTH COMPARISON OF BALSA WOOD AND SPRUCE

It is thought that the first person to make any extended commercial use of balsa wood was Capt. A. P. Ludin, President of the Welin Equipment Company, and formerly connected with the Pacific Mail Steamship Company. From his travels in tropical waters Capt. Lundin knew of the extreme lightness of this wood, and its value as a buoyancy material in life preservers and life-boats was suggested by its properties. When he undertook to apply the wood practically, however, he found that it was of little value because it absorbed moisture in great quantities, and also because it soon rotted, and also warped and checked when worked. He then undertook the discovery of some means of treating the wood which would render it waterproof and also prevent it from changing its shape. After testing nearly every method that had been suggested, Col. Marr's method of treating woods, which had been recently patented, was finally successful. In this method the wood is treated in a bath, of which the principal ingredient is paraffin. by a process which coats the interior cells without entirely clogging up the porous system. The paraffin remains as a coating or varnish over the interior cell walls, preventing the absorption of moisture and the ill effects as to change of volume and decay which would otherwise take place; it also prevents the bad effects of dry rot, which follows the use of any surface treatment for preserving wood of the balse type.

The Marr process tends to drive out all water and make the wood water-proof; it improves the quality of being readily worked with tools, without material increase of weight.

---

* Except where otherwise noted, these tests were mad e at Cornell University.

The AIRCRAFT TRADE REVIEW

Merger of Wright-Martin with Motor Company Under Way

Negotiations are in progress involving a merger of the Wright-Martin Aircraft Corporation and the International Motor Truck Corporation. Hayden, Stone & Co. are acting as the bankers in the deal.

It was said that the consolidation would be effected by having the motor truck company take over the business of the Wright-Martin property. The latter, it was stated, would continue to manufacture aeroplane motors only as the business was offered. The activities of the new corporation will be confined mainly to the manufacture of motor trucks.

Official denial was made of reports that the merger will be followed by the retirement of the Wright-Martin preferred stock, of which $5,000,000 is outstanding. It is likely, however, that the 7 per cent dividends which have been cumulative since November 1, 1916, will be paid off in cash.

When the Wright-Martin Aircraft Corporation was incorporated, on September 13, 1916, it acquired the Wright Company, the Glen L. Martin Company, the Simplex Automobile Company, the Wright Flying Field, Inc., and the General Aeronautic Company of America, Inc. The plants are located at Los Angeles, Cal.; New Brunswick, N. J.; Hempstead Plains, L. I., and Port Washington, L. I.

An interest of the company said yesterday that it was intended to complete its contracts with the United States government for Hispano-Suiza motors. After this has been done it is estimated the company, after paying all debts and collecting all bills, will have in the neighborhood of $7,000,000 cash, plus the New Jersey plant, which is estimated to be worth about $2,500,000.

Motors of C-5 Gave Good Account of Themselves

Oakland, Cal.—The engines of the navy dirigible C-5, which drove her from Montauk, L. I., to St. John's, N. F., a distance of 1,110 miles, in 23 hours 50 minutes, an average speed of 43 miles an hour, were constructed in the plant of the Union Gas Engine Company.

Less than 200 gallons of gasoline and a little more than six gallons of oil were consumed on the trip. This is considered remarkable by local engine builders, in view of the heavy weather encountered.

The telegram to Fischer, which is from S. H. Blackburn, chief in charge of the C-5, and is dated St. John's, May 15, reads: "Motors on C-5 dirigible made trip fine without any attention from Montauk, L. I. Up twenty-six hours. Expect to leave for England in the morning if ship is ready."

G. S. Ireland Runs the First Exclusively Aeroplane Salesroom

G. S. Ireland has the distinction of being the first man in the United States to open up a showroom and sales office devoted exclusively to the marketing of commercial aeroplanes.

Mr. G. S. Ireland, President and General Manager, Curtiss Eastern Aeroplane Co. of Philadelphia

Mr. Ireland is president and general manager of the Curtiss Eastern Aeroplane Corporation of Philadelphia and he will act as distributor of Curtiss aeroplanes and flying boats in that territory.

In addition to his showroom, Mr. Ireland is planning to operate a land and water-flying school and he has recently opened one of the most modern landing fields in the country.

Before the outbreak of the war, Mr. Ireland had learned how to fly at the Curtiss school at Miami, Fla. He offered his services to the government and was made a civilian instructor at Mineola. Later he was sent to Rich field, at Waco, Texas. He left Waco, to take charge of the wing construction on the first Handley-Page bombing machine to be built in this country at Elizabeth, N. J. Being barred from actual flying service by the age qualifications, he enlisted in the army as a private and was assigned to the aviation section. He was later commissioned a captain in the flying service.

Geo. W. Browne Appointed Curtiss Distributor for Middle West

George W. Browne, prominent in the Middle West as a distributer for the Willys-Overland Company, has been appointed a Curtiss distributer for the middle states. He has opened offices in Milwaukee and Chicago, and Lee Hammond, recently of the United States Naval Aviation service, is manager. Mr. Hammond, who was a lieutenant commander in the navy, only recently secured his discharge. For the last few months he has been stationed on board the U. S. S. Mississippi at Guantanamo Bay, Cuba, where he conducted experiments for the Navy in launching land machines for scouting and "spotting" purposes from the decks of the battleships. He was the first man to fly from the deck of a ship. During the greater part of the war, he was in charge of all aviation activities at the Great Lakes Naval Training Station, Illinois, the largest naval training station in the world.

Personal Pars

Hal G. Trump, for the last four years manager of the Chicago office of the Green-Fulton-Cunningham Company, has joined the staff of the Campbell-Ewald Company, Detroit, Chicago and New York. Mr. Trump will make his headquarters at the Detroit office.

First Lieut. Raymond Garey, recently discharged from the Air Service, is now connected with the Academy of Applied Aeronautics in Chicago, Ill., as general superintendent. Lt. Garey's Air Service work of preparing all technical material for use in instruction in the Aviation Mechanics Schools, as well as his connection with Air Service publications, has preeminently fitted him to fill this important position.

Andrew V. Terek, recently released from the Naval Aviation Service, has returned to the Bantam Ball Bearing Co., Bantam, Conn., as master mechanic in charge of the upkeep of the factory.

Mr. William Beckman has resigned as experimental engineer from the Duesenberg Motors Corporation to become engineer and eastern representative for the Beckman Metal Products Co., whose main offices are located at Cleveland, Ohio.

Mr. R. L. Corey, recently appointed Manager of the Chicago office of the National Gauge & Equipment Company, located in the Railway Exchange Building, was formerly associated with S. F. Bowser & Company, Fort Wayne, Indiana.

During the war Mr. Corey was Assistant Manager in charge of aeroplane instruments in the Production Engineering Department, Bureau of Aircraft Production.

Electrically Operated Tachometer Successfully Designed

A successful aeroplane tachometer employing electric drive for use on aeroplanes and dirigibles is described in the German publication, *Der Motorwagen*. The device consists of a small D.C. generator driven from the engine shaft, which acts as transmitter. The current generated is received by a moving coil galvanometer whose scale is graduated in revolutions per minute.

The armature of the generator is of drum type, and permanent magnets made of high alloy tungsten steel provide an even magnetic field, the whole being enclosed in a dustproof bayonet-joint cap. The moving coil of the receiving galvonometer is wound on a pressed copper frame and fitted with flat spiral springs which also serve as leads from the generator. The instrument is known as the Morel Electric Indicating Tachometer.

Chicago-Cleveland Aero Mail Route Makes High Record of Reliability

The Air Mail Service established May 15, 1919, between Chicago and Cleveland, has completed a very remarkable record of dependability for the first week of its operation.

A report of the weeks' operations shows that 4,160 miles have been flown out of a possible 4,480 miles and 28 trips made out of 30, scoring 93 1/3 per cent performance. There was not a single forced landing for any reason. A 43-mile gale prevented the two flights which were missed.

From Cleveland westbound to Chicago a total of 87,200 letters were carried for the week, and 74,600 letters eastbound from Chicago to Cleveland.

The average flying time for the week from Cleveland to Chicago was 3 hours and 40 minutee, and from Chicago to Cleveland 3 hours and 20 minutes, the difference being due to the prevailing head winds from the west. The distance between Chicago and Cleveland is 325 miles. The best time made was on one trip from Chicago to Cleveland in 2 hours and 48 minutes. The longest time was 4 hours from Cleveland to Chicago.

G. G. Budwig in Charge of Testing and Delivering New Mail Planes

G. C. Budwig, whose photograph we published last week, and who is in charge of the testing of the new De Haviland mail planes at Belmont Park, N. Y., and who flies the machines to Bellefonte, Pa., and Cleveland, Ohio, for final delivery to the Western Division of the Aerial Mail Service, learned to fly on a Wright hydroaeroplane early in 1914. When he had completed his instruction, he engaged in exhibition and passenger carrying work. After a period of inactivity, he resumed flying at the outbreak of the war, when Budwig went to the Curtiss school in Buffalo and learned the "Dep" control. Thereafter he worked as civilian flying instructor at the following government fields: Chaunte Fields, Kelly Field, Rockwell Field, and March Field.

While at San Antonio, Budwig also acted as Chief Instructor of the Stinson School of Flying. At Rockwell Field he was at first Dual Instructor and later Acrobatic Instructor. For two months following his transfer to March Field, he was an instructor in acrobatics, and was then advanced to Stage Commander of Final Review. He remained in the government service until the position of Civilian Flying Instructor was abolished by the Secretary of War.

Lester F. Bishop, the first aerial mail pilot to carry letters from Chicago to Cleveland

Lester F. Bishop Made Pioneer Mail Flight of Cleveland-Chicago Route

Lester F. Bishop, the first Air Mail pilot to carry mail into Cleveland from Chicago, entered the air game as a mechanic for the Champion Aeroplane Company of Chicago, Illinois, in 1915. He received his first training in flying in the spring of 1916 and until June, 1917, was connected with Eddie Stinson and R. F. Shank in conducting the National School of Flying at Houston, Texas. In June, 1917, he was appointed Student Flying Instructor at Chanute Field, Rantoul, Illinois. In September, 1917, he was transferred to the Selfridge Field, Mt. Clemens, Michigan, and on December 1st was transferred to the Rich Field at Waco,, Texas, at which field he was assigned as acrobatic instructor. He remained at this field until July 15, 1918, when he was assigned as test pilot for the Bureau of Aircraft Production, Detroit District, testing the DH4 Bombing planes preparatory to their being shipped overseas. He was engaged in this work until his appointment in the Aerial Mail Service on December 27, 1918. Up to the present time he has flown over 1,500 hours with but two slight accidents.

Only One Forced Landing on Cologne Mail Route

London.—The aerial mail service between Maiscoucille and Cologne, a distance of 225 miles, reports that after three weeks of operation there were only three days when the weather prevented the mails being carried, and there was only one forced landing; 465 bags of mail were carried, and the average time for all flights was 2 hrs. 16 min., while the record was 1 hr. 45 min. On the majority of days on which the mails were carried from March 1 onwards it was found impossible to continue the training of the homing pigeons attached to the unit. Moreover, as it was necessary to fly through driving rain, specially protected propellers had to be supplied, as the rain so seriously damaged the ordinary type during one journey that they became unsafe for further use. D.H.-9A planes, operated by the 110th Aero Squadron, are used.

Book Review

AEROPLANE CONSTRUCTION AND ASSEMBLY, by N. W. Leslie and J. T. King. This book is an excellent treatise for the aeroplane mechanic. The first section of the book is devoted to nomenclature and definitions. A comprehensive set of diagrams gives the location of every part of the fuselage, wings and controls. Then follow instructions for unpacking a plane and setting it up, and adjusting and truing the wings. Installation and care of the motor, inspection and preparation of the engine before flights is adequately dealt with. Care, alignment, balancing and checking the pitch of propellers is described in terms which are easily comprehended by the aeroplane mechanic. The care and inspection to be given a plane after flight is the subject of several comprehensive pages.

The second part of the book is devoted to a study of the materials used in the construction of an aeroplane and the theory of flight. The qualities of the various types of wood used for different purposes, the design of all types of shackles, turnbuckles, fittings of all types, strut sockets, clevis pins and cables are described and illustrated. A section of this part of the book is devoted to a discussion of methods of aligning the fuselage and correction of mistakes in rigging.

NAVAL and MILITARY AERONAUTICS

Sales of Surplus Aircraft Supplies

Washington, D. C.—According to an official statement from the Director of Sales, the sales of surplus materials have been as follows:

	Mar. 15-21	Mar. 22-28	Mar. 29 April 4	April 5-11	Total
Bureau of Aircraft Production	$11,093		$59,302	$105,620	$1,092,645
Dept. of Military Aeronautics	52,484	$5,310	2,780	6,686	466,436
Totals	$63,577	$5,310	$62,082	$120,306	$1,579,181

Of the amounts of which the cost is known, the following statement is made regarding the ratio of cost to amount received: The Bureau of Aircraft Production received $1,089,186 for material costing $1,211,825, or 90 per cent. of its cost. The Department of Military Aeronautics received $455,436 for material costing $625,772, or 73 per cent. of its cost.

Sales by the Bureau of Aircraft Production since the above tabulation were as follows: Week ending April 18, $8,099; April 25, none; May 2, none; May 9, $16,856, making a total of $1,450,528 since November 11.

For the Department of Military Aeronautics, the figures are as follows: Week ending April 18, $5,096; April 25, $1,775; May 2, $423; May 9, $20,911, making a total of $493,661 in sales.

Balloon Flights Reveal Metereological Data

A balloon ascension to study upper currents and meteorological conditions over Nebraska, Arkansas, Missouri and Mississippi under influence of the great rivers, was carried into effect recently from the United States Army Balloon School, Ft. Omaha, Nebraska.

Lt. Col. J. W. S. Wuest's balloon, maintaining a 5,000 elevation, landed at 2:30 in the afternoon near Little Rock, Arkansas, 500 miles, having been in the air 16 hours. Capt. Goodale's balloon, maintaining 10,000 feet, landed at 1:30 P.M. at Arcola, Miss, 600 miles, having been in the air 15 hours, the speed being faster at the higher elevation. The upper currents confirm the theory of meteorologists in running parallel to isobars. Other scientific data is in course of preparation from notes taken on the voyage.

Target Practice Required of Air Service Men in Aerostatic Branch

Instructions are being issued prescribing target practice for the Air Service. These instructions apply only for this season. For Lighter-than-air Organizations rifle and pistol practice is prescribed for those armed with these weapons. Heavier-than-air Organizations will not be required to participate in target practice for 1919 unless it obviously does not interfere with other work, and Air Service personnel, not included in either category, will be excused from target practice during the season of 1919.

Plane and Engine Deliveries Before and After Armistice Announced

Washington, D. C.—The following is an official statement from the Statistics Branch of the General Staff.

All orders for planes and engines have been completed except one order for Hispano-Suiza 300 H.P. service engines, which is forecast for completion in May.

The number of planes and engines delivered before and since the date of the armistice, with the percentage distribution, is shown in the following table:

ARTICLE.	Before Armistice.	Since Armistice.	Total.	Per cent. delivered. Before Armistice.	After Armistice.
Planes.

Twelve Per Cent American Planes at West Front When War Ended

The following statement was prepared by Statistics Branch of the General Staff:

Comparison of Aeroplane Strength of Allies and Enemy Air Service at Date of Armistice

French and Belgian Front	*Number of Planes*
French	3,321
German	2,730
British	1,758
American	740
Belgian	153
Total Allied	5,972
Total Enemy	2,730
Italian Front	
Italian	812
Austrian	622

Comparison of Balloon Strength of Allied and Enemy Air Services at Date of Armistice

French and Belgian Front	*Number of balloons*
German	170
French	72
British	43
American	23
Belgian	6
Total Allied	144
Total Enemy	170
Italian Front	
Italian	32
Austrian	26

More Aircraft Contract Cancellations Withdrawn

Washington, D. C.—According to an official statement issued by the Statistics Branch of the General Staff, during the four weeks ended April 26, 1919, the Bureau of Aircraft Production withdrew cancellations and suspensions of contracts to the amount of $6,944,144, thus reducing the total cancelled and suspended contracts to $493,735,473. These withdrawals are practically all for the spare parts and accessories. Following is a summary of the value of cancellations and suspensions of contracts with the per cent suspended:

	Total Obligations	Total Suspensions	Per Cent Suspended
Chemicals and chemical plants	$15,285,255	$14,203,006	93
Instruments and accessories	12,830,326	10,517,212	82
Aeroplanes and spare parts	210,530,651	165,727,433	79
Fabrics, lumber and metals	9,347,244	6,926,223	74
Engines and spare parts	410,188,300	276,062,132	67
Balloons and supplies	16,442,168	9,497,494	58
Miscellaneous	22,369,092	10,801,973	48
Total	$696,993,036	$493,735,473	71

From the date of the armistice to April 26, 1919, cancelled and suspended contracts representing an original value of nearly $118,000,000, have been liquidated at a saving of over $92,000,000 or 78 per cent.

In the following diagram is shown the per cent of actual saving and per cent cost of termination of contracts, for various items:

	Value of Cancelled Contracts	Termination Charges	Per Cent Actual Saving	Per Cent Termination Charges
Balloons and supplies	$3,834,664	$613,032	84	16
Engines and spare parts	96,385,892	20,752,433	78	22
Fabrics, lumber and metals	3,810,088	833,140	78	22
Aeroplanes and spare parts	4,346,850	1,073,622	75	25
Chemicals and chem'l plants	7,308,948	1,939,890	73	27
Instruments and accessories	1,340,972	393,994	71	29
Miscellaneous	912,611	193,032	79	21
Total	$117,940,025	$25,799,143	78	22

The present status on Bureau of Aircraft Production contracts of which these were $696,993 outstanding on November 9, is as follows: Reduced by termination, $493,375, or 71 per cent; by delivery, $193,000 or 28 per cent.; outstanding $10,258 or 1 per cent.

Air Service Withdrawals From Appropriation Light

Washington, D. C.—A balance of $144,088,000, or 60 per cent., remains of the $360,527,000 appropriation to the Bureau of Aircraft Production on April 30. The Department of Military Aeronautics has a balance of $83,305,000, or 78 per cent. of its $107,476,000 appropriation in the treasury.

Special Training for Military Observers Planned

Washington, D. C.—Realizing the qualifications and technical knowledge required to successfully perform the duties of an aerial observer, special training is being planned by the Division of Military Aeronautics for the development of reserve officers for this line of duty.

Aerial observers must be familiar not only with the duties of the military aviator, but also with the work of the artillery officer, requiring a thorough grounding in the science of ballistics.

Students electing aerial courses under the R. O. T. C. are to be sent to air depots and gunnery or artillery schools to complete their training during the summer months. It is considered likely that flying training will be given to observers, even though their work does not require their being qualified military aviators.

Balloon Base to be Established at Camp Dix

Camp Dix, N. J.—That the United States is to establish its largest dirigible balloon base in this immediate vicinity became known today when a government balloon commission selected a site close to the camp. The tentative plans call for the where work on the dirigibles will be de- establishment of a balloon training school veloped.

Army Air Ferry at Stamford

Stamford, Conn., May 28.—An army aerial ferry has been established between Stamford and Mineola to convey recruits for the air service who desire to travel that way. All recruits in this district who desire to make the trip by air are sent here. Herbert Oeser, a Stamford recruit with previous military experience, was the first one to make it to-day. He went over in a plane piloted by Lieutenant Beau.

Special Orders Nos. 120-122

Capt. Samuel E. Jackson, report to Camp Devens, Ayer, Mass., for discharge.

Col. James E. Fechet, proceed to Fort Sam Houston, San Antonio, Tex., and report to the commanding general Southern Department for duty as department Air Service officer.

Capt. Herbert A. Thorndike, report to aviation repair depot, Montgomery, Ala.

Second Lieut. William T. Howley is transferred to Walter Reed General Hospital, Takoma Park, D. C., for further observation and treatment.

Second Lieut. William E. Cloe will proceed to Boston, Mass., and report to the district manager, Aircraft Finance, Little Building, Boylston and Tremont Streets.

Par. 210, S. O., No. 88-O, April 15, 1919, W. D., as directs First Lieut. George R. S. Denton to proceed to Camp Bragg, Fayetteville, N. C., is revoked.

So much of Par. 108, S. O., No. 112-O, May 13, 1919, W. D., as relieves the following-named officers from duty at Godman Field, Camp Knox, Ky., and directs them to proceed to Camp Gordon, Ga., is revoked: Second Lieut. Harry W. Langmead, Second Lieut. James E. Jones.

Leave of absence for five days is granted First Lieut. Matthew H. O'Brien.

Second Lieut. Franklin B. Russell is announced as on duty requiring him to participate in regular and frequent aerial flights from July 13, 1918.

First Lieut. Charles Robert Herold, report to Air Service Flying School, Brooks Field, San Antonio, Tex., and by letter to the Director of Air Service, Washington, D. C.

First Lieut. John Y. York, Jr., proceed to Dayton, Ohio, and report to the Chief of Engineering Division, Air Service, for temporary duty; then to Washington, D C., and report to the Director of Air Service for duty.

Second Lieut. Norman R. Wood, proceed to Washington, D. C., and report to the Director of Air Service.

Lieut. Col. Arthur J. Hanlon will proceed to Rockwell Field, San Diego, Cal., take station, assume command, and report by letter to the Director of Air Service, Washington, D. C.

Par. 27, S. O., No. 112-O, May 13, 1919, relating to Lieut. Col. Arthur J Hanlon is revoked.

Capt. David H. Young is relieved from further duty at Hazelhurst Field, Mineola, Long Island, N. Y., and upon expiration of his present leave of absence he will proceed to Dayton, Ohio, and report to the Chief, Engineering Division, Air Service, for temporary duty for the purpose of testing and witnessing flights of bombing planes; thence to Washington, D. C., and report to the Director of Air Service for duty.

Capt. William H. Smith is relieved from treatment at United States Army General Hospital No. 2, Fort McHenry, Md., and will proceed to Air Service depot, Garden City, Long Island, N. Y.

The following-named officers are relieved from their present assignment and duties in the Office of the Judge Advocate General, this city, and will report in person to the Director of Aircraft Production: First Lieut. John W. Halsey, Second Lieut. Robert N Denham, Jr.

Capt. Thomas B. Cassels is detailed for duty under the direction of the Director of Purchase, Storage and Traffic, and will report to the commanding officer, aviation general supply depot, Middletown, Pa., for duty as camp supply officer.

First Lieut. Franklin O. Carroll, proceed to Washington, D. C., and report to the Director of Air Service.

First Lieut. Edward H. Guilford, proceed to Fort Hancock, N. J., on temporary duty in connection with tests on long distance fire control, thence to Hazelhurst Field, Mineola, Long Island, N. Y.

Par. 84, S. O., No 107-O, W. D., May 7, 1919, directing Second Lieut. Robert K. Lloyde to proceed to Washington, D. C., is amended so as to direct him to proceed to March Field, Riverside, Cal.

Second Lieut. Leonard D. Weddington, proceed to Washington, D. C., thence to Langley Field, Hampton, Va.

First Lieut. Homer E. Whitney is relieved from further treatment at the United States Army General Hospital No. 2, Fort McHenry, Md., and will proceed to Air Service depot, Garden City, Long Island.

First Lieut. Schuyler E. Grey is relieved from further treatment at the United States Army General Hospital No. 2, Fort McHenry, Md., and will proceed to Air Service, Garden City, Long Island, N. Y.

Second Lieut. Daniel P. A. Willard is relieved from duty at United States Army General Hospital No. 31, Carlisle, Pa., and will proceed to United States Army General Hospital No. 11, Cape May, N. J.

Side view of the Curtiss "Hornet", model 18-B, two-seater biplane. It has a speed of 163 m.p.h. and climbs 16,000 feet in 10 minutes, with light flying load

FOREIGN NEWS

Adjutant Casale Makes 31,000 Foot Altitude Flight

Paris, May 28.—Adjutant Casale, a French aviator, in a flight for altitude ascended 31,000 feet. This constitutes a world's record.

Adjutant Casale, during the war, had numerous fights in the air and was credited with having downed twelve German machines.

Major Schroeder, U. S. Air Service, has held the world's altitude record of 29,500 feet for several months.

Aerial War on Revolting Arabs Saved Englishmen from Massacre

Assiut, Egyt.—Dr. Allgood, who had the chair of science at the College of Assiut, was one of the 400 foreigners who held off 5,000 Fellaheens and Senyussi Arabians in a siege lasting three days.

Following the murder of one Englishman and the cutting of communication wires, the 400 foreigners formed a garrison and prepared a place of defence. Two days of fighting resulted in the practical expenditure of all ammunition, but the certainty of a general massacre on the part of the natives made resistance imperative.

After two days of fighting a seaplane came from Cairo, about 250 miles to the north of us, manœeuvred overhead and then flew away. The besiegers saw it and renewed attack. A few hours later the 'plane came again, flying low and with good aim dropped a supply of ammunition into our stockade.

Later in the day another 'plane, which we afterward learned was laden to capacity with bombs, came down from Alexandria and with deadly aim bombed the enemy village, killing about 500 natives. On the third day our hopes brightened, for more aeroplanes came up and, flying low, poured a steady and it seemed never ending machine gun fire into the opposing forces. Finally gunboats coming up the river routed the Arabs and rescued the hard pressed garrison.

American Naval Aviator Flies from Copenhagen to Stockholm

Stockholm, May 27 (By the Associated Press).—Captain Batt, an American naval aviator, arrived here in his aeroplane at 10 A.M. May 26, having completed the final lap of his 350-mile trip from Copenhagen.

Captain Batt left Copenhagen in the evening of May 24 and made his first stop at Calmar, in Southern Sweden, 175 miles from his starting point, which he reached at 12:20 o'clock Sunday afternoon. Leaving there at 7 o'clock the same evening, he flew 150 miles to Nynashamn, a small port about twenty-five miles southwest of Stockholm. Taking the air again about 10 o'clock that night, he attempted to reach this place but lost his direction in the darkness and was forced to descend at Furusund, west of Stockholm.

International Aeronautic Federation Urges Air Ministries for All Nations

Paris, May 22.—The International Aeronautic Federation, in session here, has unanimously voted the following requests for the delegates from each country to present to their government representatives in charge of aerial affairs:

That the liberty of aerial navigation be re-established as soon as possible in conformity with the decision of the Peace Conference.

That civilian aeronautics in the various countries be placed under the control of the Aviation Ministry or Department.

That all the aero clubs affiliated with the International Aeronautic Federation be represented upon the International Commission on Aerial Navigation, which is to be created after peace is signed.

That in every country the National Aero Club be represented in the National Commission on Aeronautics.

Certain conditions under which the brevet of pilot aviator may be obtained were altered by the federation, and it was decided that regulations relative to the verification of aerial achievements should be modified. Other questions were carried over for the next session of the federation, which is to be held at Brussels in October.

Pershing's Orders to Liggett Go By Aeroplane

Coblenz, May 22.—Lieutenant General Liggett's headquarters at Coblenz received for the first time several packages of documents and orders from Paris by aeroplane. The journey was made in less than five hours and required only one relay.

D'Annunzio Resigns Commission in Italian Army

Rome, May 25.—Gabriele d'Annunzio, the poet-soldier, has resigned his Lieutenant-Colonelship in the aviation branch of the Italian Army.

Commercial Flying to Be Government Monopoly in Canada

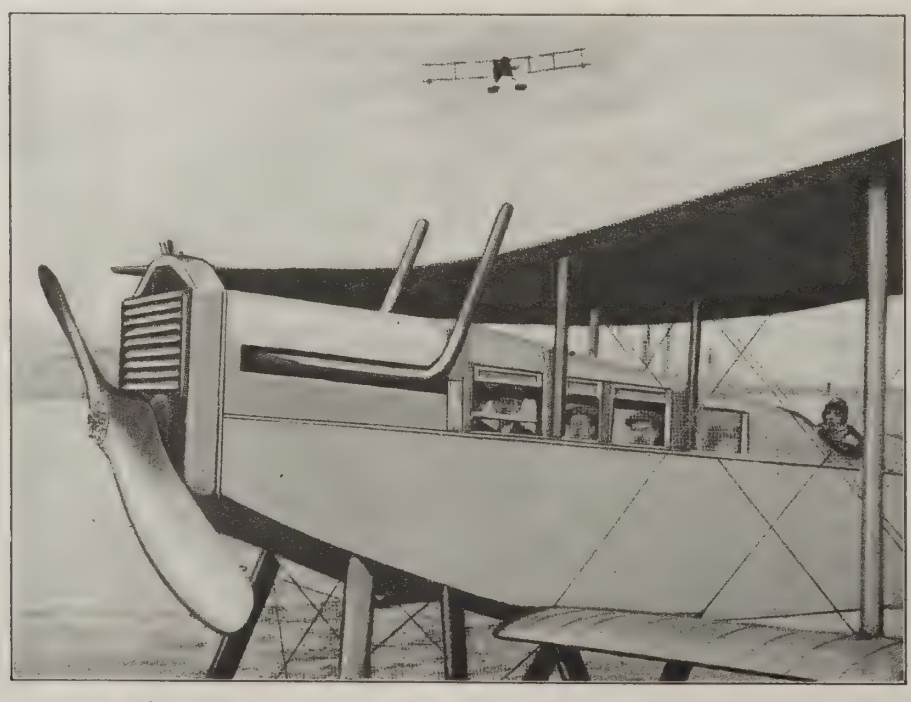
The bill providing for the control and encouragement of flying in all its aspects, the issue of licenses, inspection of machines, and arrangement of air routes has reached its third reading in the Canadian Parliament. It is proposed to make the control of commercial flying a public monopoly.

Holt Thomas Suggests Employment of Aeroplanes in Handling Press News

In the course of his lecture on April 30, under the auspices of the Industrial Reconstruction Council, Mr. Holt Thomas outlined a scheme for combining the services of the aeroplane with the telephone and telegraph in the transmission of long urgent messages, which would be called aerograms. He said the general idea was to telephone or telegraph a message to the aerodrome where it would be taken down in shorthand, carried, say, to France in a plane, and dispatched from there to its destination. Such a system, he thought, would be invaluable for dealing with long Press cables. A message of 3,000 words between Paris and London could be delivered by aeroplane long before it had got across the cable. Moreover, the aeroplane would probably be carrying millions of words and other things as well at the same time. The economy in labor by the use of such a method would be enormous.

Handley Page Offered $5 an Ounce for Aerial Delivery from England

Messrs. Handley Page, Ltd., have been approached during the month by a commercial house which wished a quotation to transfer some scent essences from Shanghai to London by air. Provided the conditions of quick delivery could be satisfied, the price, they said, might range up to £1 per ounce. There is very little doubt but that within a year from date most lightweight transport, where great speed is essential, will go by aeroplane or airship. Important mails, legal documents, and, in urgency cases, bullion are obvious goods for air-express.



Paris-Geneva Service Opened

Geneva, May 26.—The Swiss airman, Durafour, carrying mails, made the first Paris to Switzerland flight on May 26, landing at Geneva.

The time of the flight was five and a half hours, including a half hour's forced landing on French soil owing to the fog. The distance is about 250 miles.

British Government to Restrict Long Ocean Flights

London, May 28.—The British Government was asked in the House of Commons recently by Sir Arthur Fell, the Channel Tunnel advocate, to consider the question of forbidding the flight of aeroplane over wide stretches of sea until aeroplanes have proved that they are capable of making flights over land of equal length with reasonable certainty.

The Short passenger carrier equipped with a 260 horsepower Maori engine

Aeronautical Commission at Peace Conference Has Completed Its Work

Paris, May 27.—The Aeronautical Commission of the peace conference has agreed to a complete draft of an air convention and its annexes, subject to some small amendments.

The convention itself deals with the following matters:

The nationality and registration of aircraft.

General principles governing the right of international flight.

Certificates of air worthiness and competency.

Principles governing flight over foreign territory.

Rules to be observed on departure or landing and when under way.

Prohibition of the carriage of certain objects.

The international commission for air navigation .

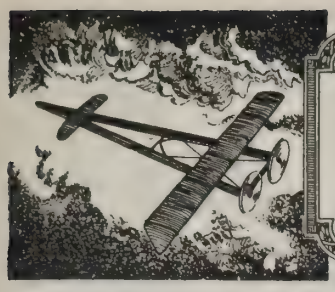
Final provisions:

Technical details are relegated to annexes in the following order:

The making of aircraft.

Certificates of air worthiness.

Log books.



Rules as to lights and signals, and rules of the air.

Certificates of competency, including medical requirements.

International maps and ground marks.

Meteorological information.

Customs.

Model Aeroplane Contest Prizes

The medals and the cup for the coming model aeroplane contests have been selected from a large stock of aeroplane jewelry and trinkets manufactured by the Arthur Johnson Mfg. Company, 14 Church Street, New York City. To say they are the most attractive ever offered for an event of this kind would be putting it mildly.

The cup for the scale model prize is of bronze of a very pretty design with two handles, and etched with silver. The interior is lined with gold. On the face of the cup are engraved the words AERIAL AGE TROPHY.

The medals of gold, silver, and bronze have on the face a figure of Victory holding a wreath in her extended hand. Under the wreath is a miniature aviation corps emblem, namely; a propeller with wings extending on each side from the propeller hub. This is in silver, which adds greatly to the appearance of the medals.

On the back of each medal the words AERIAL AGE MEDAL are engraved. The winners can have anything they desire engraved on the medals as sufficient space is left for this.

The winners of the above prizes will be envied by every model flyer who is not lucky enough to possess one, and when the next set of events comes around we will have to hold elimination contests to keep down the number of competitors.

The continued good weather of the last two weeks has brought out many good model flyers in this vicinity, and we hope out-of-town clubs are having the same good fortune.

I have received letters asking whether it is too late to enter the contests. It is not too late, in fact you have until the last day of June to compete, but I should not advise waiting until the last minute, as something might happen to prevent the contest being held, such as bad weather, or lack of witnesses.

By the time this issue is in your hands the contest will have begun and, let us hope, new records made.

Scale Model of the Loening Monoplane

The model shown in the accompanying photographs was made by the members of the Aero Science Club of New York.

This model is correct in every respect, regulation ribs, spars, etc., being used.

The engine is only a dummy, but is made exactly to scale of the 300 H.P. Hispano-Suiza engine, and can be clearly seen in the photograph. The model was made from plans which appeared in AERIAL AGE some time ago. The wings are covered with silk and the wing section is true to scale. This is the type of model which will be exhibited in the scale-model contest, and many of the members of this club are hard at work on other types.

The Aero Science Club is the oldest model club in existence and is ready to accept anybody into the club who is interested in aviation, whether it be in the models or in the larger machines. These young men are all hard workers and are strict students of aerodynamics. They are lucky inasmuch as they have on the membership list some of the oldest aeronautic men in the country, who are advisers of the club.

Two of these men are noteworthy: Mr. Durant, whose father was the first to jump from a balloon in this country, and Mr. S. Y. Beach, for some time Aeronautic Editor of the *Scientific American*, and an inventor of many aeroplane parts.

If you have any clear photographs of models send them to the Model Editor, and if they are of interest to the readers we will reprint on this page.

Should a young man continue to build models all his life, and not branch out to the study of the larger machines?

This is a question that many model fliers ask themselves, and a great number ask me, so I will answer it. After you feel sure that you know every trick and turn of model flying and you get so you can make scale models fly, by all means turn to the higher problem of aerodynamics, and if you cannot design, try to build a machine to carry at least one passenger. Many companies are advertising parts for light aeroplanes, and almost any model flier has the facilities for building and assembling a small size man-carrying aeroplane.

Most of the old-time model aeroplane builders built large machines soon after they took up model flying, and many of them taught themselves to fly These young men are to-day the best aeronautic engineers in the country, and are holding responsible positions with the Government and private concerns.

I intend starting another series of articles on the large machines in the near future and will devote most of the space of this page to this type of machine for about four or five issues. It is hoped that these articles will be received with as much favor as the last series covering the Design and Construction of the FORD MOTORED AEROPLANE.

Scale model of the Loening Monoplane, built by the members of the Aero Science Club

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Shakespeare as an Airman

I. The Squadron.

". . . All furnish'd, all in arms,
All plum'd, like estridges that wing the wind,
Bated, like eagles that have lately bath'd."
(*Henry IV, Pt. I, IV.*, 1.)

II. The Pilot to His Machine.

"When I bestride him, I soar, I am a hawk."
(*Henry V., III.*, 7.)

III. The Pupil to His Instructor.

"We could not stall together."
(*Antony and Cleopatra, V.*, 1.)

IV. The C.O. (*loq*).

". . . The air
Nimbly and sweetly recommends itself
Unto our gentle senses."
(*Macbeth, I.*, 6.)

"Ah! Stand by."
(*Antony and Cleopatra, III.*, 9.)

V. Chorus of Night-Raid Pilots.

"Sweet moon, I thank thee for thy sunny beams;
I thank thee, moon, for shining now so bright."
(*Midsummer Night's Dream, V.*, 1.)

VI. Chorus of Mechanics.

"Fly! Not we!"
(*Antony and Cleopatra, III.*, 9.)

VII. The Transport Officer.

"I am no Pilot."
(*Romeo and Juliet, II.*, 2.)

VIII. Taking Off.

"Now to the Goths, as swift as swallow flies."
(*Titus Andronicus, IV.*, 1.)

"The deep damnation of his taking-off."
(*Macbeth, I.*, 7.)

IX. In the Air.

"By heaven, methinks it were an easy leap
To pluck bright honour from the pale-faced moon,"
(*Henry IV., Pt. I., I.*, 2.)

"For courage mounteth with occasion."
(*King John, II.*, 2.)

". . . Flies an eagle flight, bold and forth on,
Leaving no tract behind."
(*Timon of Athens, I.*, 1.)

"In the clouds, scorning the base degrees
By which he did ascend."
(*Julius Caesar, II.*, 2.)

"To be imprisoned in the viewless winds,
And blown with restless violence round about
The pendant world."
(*Measure for Measure, III.*, 1.)

"Servile to all the skyey influence."
(*Measure for Measure, III.*, 1.)

X. Over the Lines.

"Witness these trenches made by grief and care."
(*Titus Andronicus, III.*, 2.)

XI. The Observer.

". . . His pilot
Of very expert and approved allowance."
(*Othello, II.*, 1.)

"Why, that's my dainty Ariel."
(*Tempest, V.*, 1.)

XII. The Engines Fail.

"And O you mortal engines, whose rude throats
Th' Immortal Jove's dread clamours counterfeit,
Farewell!"
(*Othello, III.*, 3.)

XIII. Hope.

". . . Why may not I
Glide thither in a day?"
(*Cymbeline, III.*, 2.)

XIV. The Last Chance.

". . . Let her down the wind
To prey at fortune."
(*Othello, III.*, 3.)

XV. The Crash.

"Oh, what a fall was there, my countrymen."
(*Julius Caesar, III.*, 2.)

"Sir, sir, thou art so lucky
That we must leave thee to thy sinking."
(*Antony and Cleopatra, III.*, 2.)

"Will this gear ne'er be mended?"
(*Troilus and Cressida, I.*, 1.)

The Seven Ages of Man

(By Air-Mechanic W. Shakespeare)

The R.A.F.'s a stage,
And all its *personnel* are merely players;
They have their crashes and calamities,
And each man in his time breaks many parts.
First the fledgling, mewling and puking in the dizzy heights.
Then the first *solos*, with torn and grimy face,
Creeping like snail, ungainly, from the hedge.
Then the subaltern, sighing like furnace,
With woeful ballad penned to the lady driver.
Then the Captain, full of strange jests (somewhat like Wilkie Bard),
Seeking the bubble reputation, even in the Archie's mouth.
Then the Major, too fat to fly, with oak-leaves on his hat,
Bestriding all the place like a Colossus.
Then the C.O. (whose massive coat is interlined)
Sitting in judgment on his cowed Ack Emmas.
Last scene of all, which ends this strange eventful history,
Reveals a General at the Ministry,
Sans eyes, *sans* teeth, *sans* wisdom, and *sans* everything!

G. S. in *Flying* (London).

The NC-4 is Valsparred

ONCE more it has been conclusively demonstrated, in the most spectacular flight in history, that Valspar is the *supreme* varnish.

The Navy Department varnished the NC-4 with Valspar because of its absolute *waterproofness*, its unequalled *toughness*, and because it possesses the marvelous *elasticity* required to stand the terrific vibration of a seaplane in flight.

Here's the Original Order which specifically states that the Valspar is for the NC-4.

Valentine Products

used by the world's leading airplane makers include:

Valspar Varnish
Valspar Low Visibility Gray Enamel
Valspar Olive-Brown Enamel
Valspar Black Enamel
Valspar Khaki Enamel
Valspar Filler (Wood)
Valspar Primer (Metal)
Valspar Primer (Wood)
Valspar Aluminum Paint
Dipping, Spraying and Brushing coatings of all kinds
Quick-Drying Insignia Colors
Valenite
Valenite Enamels

as soon as it is finished will make the most complete and accurate map ever assembled.

"The initial work is now being done from the various flying fields in this country still in operation. Perhaps the most work thus far accomplished is that done at Post Field, Fort Sill, Oklahoma, where a map is now almost completed covering a strip of territory 30 miles wide and 130 miles long. This strip runs from Call Field, at Witchita Falls, Texas, to Oklahoma City, Okla., and is the work of pilots, observers and aerial photographers of the service station at Post Field.

"Most of these pictures were made from a 6,000-foot elevation from De Haviland planes equipped with a Liberty-twelve motor. The men engaged in the work have already taken 650,000 isochromatic plates, and the job has not yet been finished. When this is considered and the fact also that the pictures taken represent a strip of territory of about four square miles and each picture overlaps for about one-half mile so that no bit of ground is left out, and at the same time fits on the enormous ground board on which it is pasted, the size of the job of aerial mapping the entire United States may be realized. It is also at once apparent that the small army of airmen trained during the war period can still be mighty useful to Uncle Sam.

"When a certain section has been pictured and each developed proof been pasted, the whole is photographed and made into a large section map, and as the sections are finished they are in turn put together as were the individual pictures, in the first operation. In order to facilitate the movement of the pilots and photographers, portable hangars have been placed along the route, and the men put in eight hours a day taking pictures. Motor lorries carry dark rooms and development equipment, keeping pace with the pilots so that there is not a lost minute in developing the plates and completing the maps. If the boards on which the proofs are placed were assembled in one line it would be about a mile long and a quarter of a mile wide.

"One of the proofs of the practicability of this method of accurate map-making is the story of the military map made in this manner of the Panama Canal Zone. After a corps of engineers consisting of one regiment had spent six months in attempting to make a map of that zone and met with failure, one squadron of the air service, with twelve ships and pilots and a section of photographers were sent into the region. In two months time they had completely mapped the zone. This map has never been released by the Government because of its great military value.

"Plans have been made by the Director of the Air Service, it has been said at Washington, to map the whole country, but because of the failure of Congress so far to provide for the continuance of the air service on a large scale, the only maps now being made are in the vicinity of the flying fields still operating."

Aeronautic Instrument Development Discussed

Commercial success of the aeroplane can be assured through the use of instruments already perfected. Safety devices that constantly check up the aeroplane during its flight giving the operator a sixth sense and thus enabling him to maintain perfect control at all times and avoid pitfalls to which he would be a victim without their aid of artificial check-up.

These were the conclusions before the Second Pan-American Aeronautic Convention of Charles H. Colvin, M.E., a pioneer in the invention and perfection of aircraft instruments.

"Many pilots do not realize the extent to which they are dependent on their vision or of cloud formations below them, for maintaining the correct attitude of their plane. The only way to appreciate when an aviator is up against flying in a fog, clouds or at night, is to be there with him. Sometimes he cannot see the extremity of the wings of his planes. He cannot tell if he is level, if he is turning—that is, without instruments.

"To realize the seriousness of the stability problem we have but to refer to a recent report of the U. S. Air Service. Out of 274 fatal accidents which were reported, where the cause was known, 178, or 65 per cent. resulted from loss of control due to the plane getting into unstable positions: side-slips, skids, nose dives, stalls and tail-spins.

"For maintaining an aeroplane safely longitudinally, or fore and aft, the most valuable instrument is the air speed indicator or buoyancy meter. The reading of this instrument is a direct indication of the buoyancy or lift of the machine. It does not indicate the correct air speed, however, for at higher altitudes greater speed is necessary to maintain the proper buoyancy. A pilot will learn the buoyancy indication (erroneously indicated as air speed) which corresponds to level flight of his plane for a given engine speed. By noting both his tachometer reading and his indicated air speed he can thus tell very closely if he is descending, climbing, or flying level. Occasional reference to the altimeter will check this. A longitudinal clinometer may also be used in this connection, but is neither as reliable nor as sensitive as the air speed indicator.

"For maintaining his proper lateral attitude a banking indicator is used. This instrument has been practically ignored by the U. S. Army, which probably accounts, in a measure, for the large number of accidents due to loss of control.

"The most successful banking indicator consists of a very sensitive arrangement of pendulums so that a large indication is given for a very slight divergence from the proper lateral position. By keeping the indicator from appearing, the pilot can keep his plane level in flying straight, or properly banked in turning.

"The lateral and directional movements of a plane are closely inter-related. In turning one also banks, and vice versa, therefore we must consider directional stability at the same time as lateral stability.

"If the banking indicator only is used, the pilot may start to turn, and while still flying safe enough, he will get nowhere, going in circles. Here the turn indicator comes to the rescue. This is a small instrument using a gyroscope as a very sensitive indicator of any divergence from straight flight. Thus by keeping his turn indicator neutral—that is, indicating straight flight; and also keeping his banking indicator on center—indicating proper lateral attitude, a pilot can fly straight and level through fog, clouds or darkness.

"As the turn indicator will not show very minute turns, he occasionally checks up his course with the compass.

"It is my belief that stabilizers, particularly of direction, will come into general use and be found highly advantageous on large commercial and mail-carrying planes. In flying a plane from one point to another, fully 75 per cent. of the pilot's energy and attention is devoted to keep the plane on its course. With a directional stabilizer, this is reduced to a negligible part of his duties, as he only needs to look at his compass occasionally to check up the automatic control."

Scott during the explorer's Arctic expedition.

Frederick Wyatt of the Marconi company, who is to be the wireless operator, is now on his way to St. John's on board the steamship Sachem.

A visit to the Handley Page field and an inspection of the machine in the course of being assembled serve to convince one that the promoters of this enterprise aim to eliminate all possible chance, and that nothing of the freakish enters into their designs. At the very start they displayed good judgment in the selection of their field, and the place is regarded as the most suitable for the purpose that could be found in this country. Harbor de Grace, situated on the north side of Conception Bay, is three miles deep and one wide. The headlands of the port jut out into the bay, which is an arm of the Atlantic thirty miles deep and fifteen miles wide. At the entrance of this port on the north side the Handley Page machine is being erected. The field where the work is being done and from which the flier will take off comprises forty acres. It is 900 yards long and 200 yards wide, and has a seaward grade of 3 per cent. The local name of the place is Bear's Cove.

The principal portion of the field is owned by the Roman Catholic Church and was rented to the Handley Page company by Bishop March. In addition, there are more than twenty other owners of portions of the field. Boundary fences, telegraph lines and six farm bulidings, including two dwellings, were removed by the company. The whole field has been levelled and rolled, providing a hard surface. It lies due east and west and the takeoff can be made with the winds from the southwest to northwest and from southeast to northeast.

Reel Antenna and Accessories

The antenna reel group for this set consists of the reel mechanism, a removable drum with antenna wire and spare drums with complete antennæ on them. The wire from the reel runs through a take-off pulley and passes through the lead-in insulator in the side of the hull of the boat. It then passes through either a strut pulley, or wing pulley, depending upon the type of the boat.

Reel Mechanism

A cast aluminum plate, clamped to one of the main struts in the hull of the boat, carries a shaft on which the drum turns. On this same shaft, next to the attachment plate, there is a brake drum of cast aluminum, and around this drum a cast iron brake band. The band is sprung over the drum and prevents it from turning except when a cam which is attached to the brake lever springs it open. A pin on the brake drum engages holes in the main drum, when the latter is put on the shaft. The crank by which the main drum is turned has a square hub on which the drum sets. It is slipped onto the shaft, and latches in place. The latch is released by a latch handle just behind the arm of the crank. To remove the drum, to put a new one in place, the operator grasps the arm of the crank, and in so doing also grasps the latch handle and releases the latch. He then pulls the crank and drum off together. One drum may then be slipped off the hub of the crank and a new one put on, and the two slipped back onto the shaft.

Reel Drum and Antenna

The drum is a pressed steel spool, black japanned, and will hold about 600 feet of the standard antenna wire. It has a square hole at its center which fits the hub of the crank. The antenna wire has a ball at the reel end, and this ball is dropped through a hole in the drum face. The other end of the wire is attached to a swivel, and this in turn is attached to the "fish" or weight.

Lead-in Insulator

The lead-in insulator is a moulded "electrose" fitting, with a metal tube running through it, and a wide flare at either end, so that the wire cannot catch on the ends of the tube even if it enters at right angles. The insulator is held by lock-nuts in a hole in the side of the hull. The antenna connection from the set is brought to this insulator. When the antenna is out, the ball on the reel end of the wire rests against the inside flare of the insulator. The wire is thus entirely disconnected from the reel, and the reel is dead. When it becomes necessary to reel up, the ball is grasped, and of course brings the wire with it. The ball is passed through the take-off pulley and dropped through the hole in the drum face, and the crank is turned. The brake mechanism is arranged so that the cam may be left holding the brake off during the reeling-up process.

The equipment has given excellent account of itself. For reception, a six-valve vacuum tube receiver is used. In addition, a half-kilowatt spark transmitter driven by a fan was provided. Description of these instruments is not yet permitted by the Navy Department.

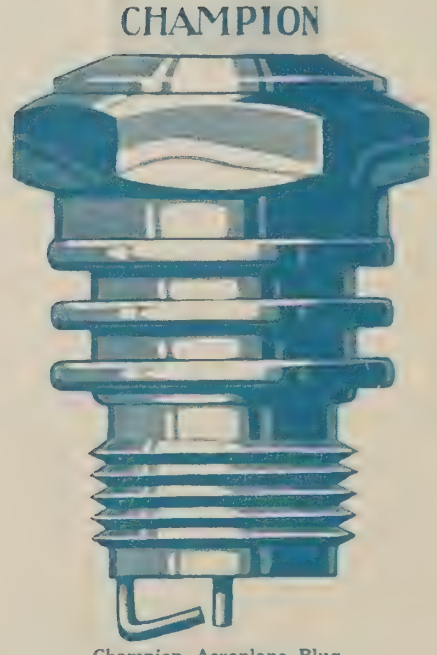
Champion Dependable Spark Plugs



Severe Air-Test Shows Dependability of Spark Plugs with No. 3450 Insulator

TO guard against possible leakage Champion Spark Plugs are inserted in our Air-Test Machine, oil is poured at the point where shell and insulator meet, and a pressure of 140 pounds per square inch of air is forced up through the base of the shell.

The absence of air bubbles means 100% Champion Dependability against leakage.

Our No. 3450 Insulator, together with our patented Asbestos Gasket construction, withstands a much greater pressure against the Insulator and enables Champion Spark Plugs to come through this test in our machine and *in your engine* with a perfect score. Insist upon Champion Spark Plugs and make sure the name "Champion" is on the Insulator and the World trade mark on the box.

VOL. IX NEW YORK, JUNE 16, 1919 NO. 14

$129,000,000 ASKED FOR AERONAUTICS

THE Army is asking $83,000,000 for aeronautics, the Navy is asking for $46,000,000.

The General Staff is supporting the plans for a substantial Air Service in the Army just as the General Staff is supporting the plans for a substantial Air Service in the Navy.

Congress seems to be in favor of an extensive program, which shall include a substantial development of the aerial mail service and shall assist the development of civilian aeronautics.

Especially gratifying is the fact that the program includes the acquisition of dirigibles from Great Britain and the construction of dirigibles in the United States.

The details of the Navy aeronautic program, as submitted to Congress, are as follows:

Aircraft for fleet use, $4,504,025.

Purchase abroad of ten special fighting and spotting planes, $200.000.

To erect one large hangar for dirigibles, $1,850,000.

To establish a rigid dirigible construction and operation station, $6,264,000.

To construct two rigid dirigibles, $400,000.

To purchase a British rigid dirigible, $2,500,000.

Conversion of collier Jupiter as aeroplane carrier, $500,000.

To purchase and convert two merchant vessels into aircraft tenders, one for planes and one for lighter than aircraft, $5,261,250.

To continue operations of all established air stations, $7,813,107.

To continue experiments and developments of all types, $9,405,000.

To equip Marine Corps advanced base units with aircraft, $3,933,100.

Miscellaneous, $300,000.

Total, $46,531,482.

It is considered significant of what the future trend of aircraft development is to be that the Navy is already asking that almost half of its appropriation shall be for dirigibles.

PREPARATIONS FOR TRANSATLANTIC FLIGHTS AT ATLANTIC CITY AIRPORT

PREPARATIONS are being made at the Atlantic City Airport for a number of projects for non-stop trans-Atlantic flights, starting from or ending at the Airport. It is understood that the projects for non-stop trans-Atlantic flights include two British, two Italian and three American plans. Three of the projects contemplate the use of huge dirigibles, and four the use of land aeroplanes and seaplanes.

Representatives of the Aerial League of America and the Aero Club of Atlantic City and prominent American Aces and naval aviators and wealthy sportsmen and business men have held a number of conferences with engineers, hangar builders and makers of hydrogen and plans are being drawn for large hangars for trans-Atlantic seaplanes and land aeroplanes and for hydrogen plans for dirigibles.

The advocates of land aeroplanes are making headway with their arguments that the large land aeroplanes equipped with multiple power plants will prove to be most efficient for trans-Atlantic flights, as they will permit starting from the Airport here and landing at the aviation fields in England, France and Italy, or vice versa.

Towers sixty-five feet high have been built to mark the ten-miles course for testing the speed of the trans-Atlantic flyers. This course is so arranged that both seaplanes and land aeroplanes can make their tests and in case of a forced landing can land on water or on land, whichever may be the most desirable.

Plans are under consideration for the construction of seaplane hangars at the extreme end of the Airport, facing the Great Thorofare which affords over ten miles of calm, protected water where tests can be conducted. Rough water tests will be conducted at the Inlet and over the ocean.

A trans-Atlantic Flight Record Hall is being established at the Airport Administration Building, where airmen will find all the charts and data available and needed for trans-Atlantic flights. This data already include numerous charts showing all the possible routes for flying across the Atlantic, the meteorologic charts and reports of meteorologic conditions to be met in crossing the Atlantic on different months of the year; instruments for aerial navigation, photographs of all the NC seaplanes, as well as the British trans-Atlantic type planes.

Mr. A. S. Abell, 3rd, is the Secretary of the Committee in charge of the trans-Atlantic flight data.

Seven hundred thousand cubic feet of hydrogen has been mobilized in different parts of the United States during the past month to be used to fill up the British dirigible R-34, which is due to come to the United States this month and is scheduled to land at the Atlantic City Airport, which affords the best unobstructed landing place in this part of the country.

An indication of the fact that permanency is contemplated was given a few days ago when Messrs. Albert T. Bell and Harry B. Cook, President and Secretary of the Atlantic City Aero Club, respectively, and Mr. W. W. Young, the noted engineer, sought to purchase two hydrogen plants from a Philadelphia firm, in addition to mobilizing over half a million cubic feet of hydrogen in steel bottles. Each of these two plants would be capable of producing ten thousand cubic feet of hydrogen an hour, therefore could supply in a short time the amount of hydrogen needed to replace the loss which a two million cubic feet dirigible would sustain in crossing the Atlantic. These plants cannot be had without permission from the War Department and a representative has been sent to Washington to secure the official release.

Invite NC-4 to Atlantic City

Secretary of the Navy Josephus Daniels was invited to send transatlantic flyer NC-4 to the Atlantic City Airport to be placed on public exhibition there in order that the hundreds of thousands of people who come from all parts of the country might be able to see it. Officials of the aero clubs are convinced that Atlantic City, because of its ever-changing population, would afford opportunity to more different people to see the famous ocean-tripper than any other place in the country and that it would prove one of the greatest boosts for aviation that could be placed before the public.

Albert T. Bell, president of the Aero Club of Atlantic City, and Samuel P. Leeds, president of the Atlantic City Chamber of Commerce, who are closely cooperating with the Aero Club of America; the Aerial League of America and the sixty-two clubs affiliated with these organizations, have extended the invitation.

Mr. Bell, in the invitation, pointed out that the Atlantic City Airport is the first and only airport in the world and one that affords exceptional facilities for land and water planes. The airport is located within a few minutes' walk of the heart of the city and 3,000 feet from the Boardwalk, and therefore easily accessible to the public. Emphasis is laid on the fact that the Atlantic City Airport is the only place where the NC-4 can be flown to and exhibited without danger of breakage through transportation, because the Thorofare waters, which form the water course of the airport, are protected and still at all times and ideally suited for large seaplanes both for take-offs and docking.

Stress is also placed upon the fact that ten million people who come to Atlantic City each year represent more territory than any similar number of persons visiting any single city in the world, who would sooner come to Atlantic City during the summer months than any other place. It is estimated that close to a million and a half people will visit Atlantic City during July alone.

The large size of the NC-4 makes it almost impossible to exhibit it anywhere else than at a naval station, where there are no facilities for accommodating the large crowds. This can easily be done at the Atlantic City Airport, and in addition there are hotel facilities to take care of any crowds that may make the trip to see the ship.

Mr. Bell also extends, through Secretary Daniels, a hearty invitation to Commander Read, Lieutenant Stone and the other members of the NC-4 crew to come to Atlantic City "to be presented to the million people representing every State and city in the United States."

Diploma Presented to Commander Read

Announcement was made of the award of the Diploma of Honor of the Aerial League of America to Commander A. C. Read, the hero of the transatlantic flight; Flight Lieutenant Stone and the other members of the crew of the NC-4, and Commander R. E. Byrd, who invented the Byrd sextant, by the Awards Committee of the Second Pan-American Aeronautic Convention.

Other prominent officers of the United States Army and Navy were awarded the League's diploma, including Major-General Mason M. Patrick, who was chief of the U. S. Air Service overseas during the war, now the U. S. Army representative on the Aeronautical Commission of the Peace Conference; Rear-Admiral D. S. Knapp, U. S. Navy representative on the Aeronautical Commission of the Peace Conference; Brig.-Gen. Theodore C. Lyster and Lt.-Col. I. H. Jones, who were foremost in organizing the Air Medical Service; Col. Halsey Dunwoods, executive officer of the U. S. Air Service overseas; Col. E. Lester Jones, Col. Charles Elliott Warren, Col. B. J. Arnold, Col. Thurman W. Bane, Col. C. G. Edgar, for exceptional services rendered to the United States during the war; Col. C. C. Culver, who developed the radio telephone; Lt.-Col. A. R. Chrustie, Lt.-Col. W. G. Kilmer, for exceptional efficiency while in charge of the U. S. Army Aviation centers in France; Col. Charles De F. Chandler and Col. Frank P. Lahm, for exceptional efficiency while in charge of the U. S. Army Balloon Service in France; Maj. J. C. McCoy, Maj. Thomas S. Baldwin and A. Lee Stevens, for exceptional efficiency in organizing the U. S. Army Balloon Service; Capt. Charles J. Glidden, for exceptional services rendered in recruiting for the U. S. Army Air Service; Maj. John M. Satterfield, for exceptional efficiency in connection with the administration of the Air Service in France during the war.

The Awards Committee had under consideration awards to 100 other high officers of the U. S. Army, Navy and Marine Corps Air Service.

Commercial Aviation Discussed

The future of commercial aviation is six miles above the earth's surface. The birdmen must get above the storm limits—weather must be eliminated from the commercial aerial log. The "altiplane," the antithesis of the submarine, will turn the trick.

These were salient points in the address before the second Pan-American Aeronautic Congress by Samuel D. Mott, M. E., an Edison pioneer, charter member of the Aero Club of America, who has just completed a special study of aeronautics with the view of future attainment:

"We have read of many men tarrying at Newfoundland for several weeks waiting—waiting for the weather. That trial was a glorious undertaking, our navy's expedient was wise, and all honor to the brave men attempting the test. But I submit that waiting indefinitely for ideal weather conditions for long-distance flying over land or sea will not do for the demands of commerce. Therefore, by the process of reasoning that Holland applied to boats to go out of sight beneath the stilled waters of the ocean, I conceive and would bring to your attention the possibilities of the antithesis of the submarine—the altitude plane, or altiplane, as distinguished from the aeroplane or hydroplane, to go into the stillness of nature above the weather.

"The problem is evidently one of equipment of our planes to function in rarefied air, and protection of navigators against its tenuity; likewise protection of their body warmth and comfort in extremes of temperature. How high we may go no one may know until tested. Personally, I believe it possible to go 15 or 20 miles aloft, if necessary. It is obviously a matter of equipment plus climbing ability of aircraft designed for the purpose.

"What is the object of high flying? Daily experience shows us that high speed and density are incompatible. We know that the surface speed of submarines is about half that of battleships; submerged, it is less, and the greater the depth still less the speed, due, in the first instance, to displacement, which is constant, and in the second place to increasing density, which is progressive. Again we know this when we furnish aircraft with four times the power to go twice as fast, or as we say, the square of the velocity; and the marine engineer knows when he furnishes eight times the power to go twice as fast, or as we say, the cube of the velocity. How well this is illustrated with our swift motorboats designed to run as high out of water as is consistent with stability, and when planes are used their hulls are entirely out of water and in the lighter air above, and when so disposed the highest aquatic speed has been attained. In other words, from the ultimate height of the air to the earth's core pressure is progressive. Thirty-three feet below the ocean's surface the pressure doubles. For every 1,000 feet ascent the pressure diminishes roughly one half pound per square inch. The pressure at two miles high is 9.8 per square inch, at one mile high 10.88, at three-quarters of a mile 12.06, one-half mile 13.33, one-quarter mile 14.2, and at sea level 14.7 pounds, or, in round numbers, 15 pounds per square inch.

"Where is the storm limit? As moisture and varying temperature is the fundamental of storms, their greatest development is near the surface and wholly confined to the storm limit. Wind strata is of varying temperature. Over the hottest regions of Africa zero conditions have been detected within 1,500 feet of the ground.

"Why must there be a storm limit? Because storms and hurricanes do not exist without moisture and heat, and air must have a certain density to hold the moisture due to evaporation. Hence there can be little or no wind above the storm limit.

"The unknown factor in the high-altitude problem is this—will an alti-plane in one-fifth density (eight miles high) with equal push go five times faster or one-fifth faster? The rest is a matter of simple equipment and good construction. In either case the gain is substantial. If the former were true, a voyage between New York and London can be made in around three hours by going eight miles high. If the latter is true the same voyage can be made in about twelve hours' running time, assuming a surface speed of 200 miles per hour, which is practically a question of power.

"In the exhibition in Aeronautical Hall is an engine which explains why we are flying to-day, and why we will fly faster to-morrow. It is a 400 H.P. Curtiss engine weighing 1.7 pounds per H.P. and has driven an aeroplane 160 miles per hour.

"To my mind, it is plain that high altitude will be a determining factor in long-distance flying. This is true for the endurance of the human machine, and limit of life of the power machine—the motor. Greater speed, greater distance, more comfort and less danger—less danger in the quiet environment, less danger because when we double the time to do a risky thing we double the risk incurred. Less gasoline, less weight and expense, for if environment permits to go 100 miles with twice the fuel we formerly used to go 25 miles our economic gain is obviously 100 per cent. because we may then go 100 miles with the amount of fuel we formerly consumed to go 50 miles."

The News of the Week

Martin Bomber to Attempt Transcontinental Flight This Week

The Martin bomber for the transcontinental flight is being tuned up for the trip, which, it is estimated, will take 32 flying hours for the 2,750 miles. Captain Roy N. Francis, who is said to have had more hours of flying than any other aviator in the Army Air Service, expects to make only one stop at North Platte, Nebraska, 1,502 miles from the starting point.

He will start from Mineola at 3:30 o'clock in the morning. His time over the principal cities on the way, with variations necessary for the wind, will be: New York, 3:37 o'clock; Cleveland, Ohio, 7.42; Toledo, 8:55; Chicago, 11:42; Des Moines, Iowa, 3:45 p.m.; Omaha, Neb., 5:11; North Platte, 8:09. The next morning, the machine will take the air at 3:30 o'clock. It will pass Cheyenne, Wyo., at 6:07; Salt Lake City, Utah, 10:55; Reno, Nevada, 3:37 p.m., and will arrive at San Francisco at 5:58 o'clock in the evening.

The machine will be the typical bombing plane which was ordered during the war for service at the front. The only modification will be that the armament will be left off and the tunnel leading from the pilot's seat to the cockpit will be utilized for gasoline tanks. The aeroplane will weigh, over all, 10,600 pounds. It will have a 71-foot wing spread, and will be driven by two 400-horsepower Liberty motors. The plane is fitted with radio telephone equipment and a radio compass.

Daily Air Taxi Service Between Boston and Shore Resorts

Boston, June 6.—The first aerial taxi service in New England of the country is being operated by the North Shore Aerial Transportation Company of Swampscott from Swampscott to Franklin Field, Boston.

The first trip, a nine minute ride by air, was taken by Mrs. Frank Wright of the Todesco Country Club, Swampscott. Advertising was dropped from the air on the trip and merchandise was taken back to Swampscott.

The company plans to make daily flights between Boston and North Shore summer resorts on express, passenger carrying and advertising business. The proposed taxi schedule of the company shows the running time to be nine minutes from Boston to Swampscott, eighteen minutes from Boston to Magnolia, and thirty-seven minutes from Boston to Portsmouth, N. H.

$50,000 in Prizes for Los Angeles-Australia Flight

Venice, Cal., June 5.—An offer of $50,000 as prizes for aviators who will attempt a flight from Los Angeles to Australia was made by Thomas H. Ince, motion picture producer. To the first man to land on Australian soil, $35,000 will be paid, according to the announcement. To the first aviator attempting the flight, who although failing to reach Australia, reaches the Hawaiian Islands, $10,000 will be paid. In the event none of those attempting the flight reaches the Hawaiian Islands, $5,000 will be paid to the one making the best showing.

Chicago Clothing Manufacturer Uses Aerial Delivery Service Over 500 Mile Radius

Chicago, Ill.—A Chicago maker of a nationally advertised brand of men's clothing announced organization of an aeroplane delivery to serve dealers within a radius of 500 miles.

At the end of the first week of selling, an automobile dealer who has added aeroplanes to his stock Saturday said that he had sold Canadian Curtiss forty planes.

Aerial Forest Patrol Discovers Its First Fire

Washington, D. C.—The War Department announced that Lieut. Donald C. Cathcart, the Post Adjutant at Ross Field (Arcadia, Cal.), discovered at 2.10 o'clock P. M. on June 6 the first fire in co-operation with the forest service from an observation balloon at an elevation of 1,500 feet, on the Lucky Baldwin ranch at the foot of Sierra Madre Mountain. Within seven minutes after the fire was located enlisted men in a special fire truck had arrived. They extinguished it after two carloads of barley hay had been destroyed. Orders were given and owners of property notified from the balloon basket by telephone.

The aeroplane patrol of Cleveland National Forest, one of the Curtiss JN-4 pattern, covered 115 miles in ninety minutes at an altitude of 3,000 feet.

The forest patrol planes are equipped with wireless and in communication with permanent stations. Good emergency landings have been provided.

The first patrol was successful. It was piloted by Lieut. J. L. Fogarty with Sergt. (first class) H. E. Wari, observer

Naval Airmen to Guide Gloucester Fishermen By Radio to Schools of Fish

Washington, D. C.—The Naval Air Service is ready to co-operate with New England fishermen whose craft are fitted with radio, according to a Washington dispatch. It is believed that this innovation will result in a considerable saving of time and expense as it will permit the fishermen to complete their catch with minimum cruising.

If the service proves successful, steps will be taken to extend it on all coasts.

The famous 94th Pursuit Squadron returns. From left to right: Capt. Sam Kaye, Lieut. R. W. Donaldson, Lieut. R. Z. Kates, Lieut. K. R. Jackson, Lieut. C. A. Rankin, Major R. M. Chambers, Lieut. D. R. Mackenzie, Lieut. A. W. Markhan, Lieut. K. E. Hopkin and Capt. W. W. Palmer

Atlantic City Airport Preparing to Receive the R-34

Atlantic City, N. J., June 8.—Announcement was made at the Atlantic City Airport today that seven no-stop transatlantic air flights will be made soon with this port as objective and "take off," respectively. The flights will be made by American, British and Italian airmen. Two and probably more will start from this port. Preparations will begin immediately for the events. Three dirigibles are included in the program. It was said that full particulars of the enterprise will be forthcoming in a few days.

Confident that the British dirigible R-34, which may begin her flight for America tomorrow, will make this city her objective, the Aero Club officials are making preparations to receive the giant "blimp." The arrangements include construction of a hydrogen plant with a capacity of 10,000 cubic feet of gas an hour in order to reinflate the dirigible. It is understood 700,000 cubic feet of hydrogen in various parts of the country will be available in case it should become necessary to call for outside assistance.

A. S. Abel, 3rd, of Baltimore, has been appointed secretary of a committee to gather transatlantic flying data.

It is the intention here to lay a ten-mile course over which sea and land planes may try out their engines during the tuning up prior to transatlantic flights.

Aeronautic Medical Apparatus to be Exhibited

At the annual meeting of the American Medical Association, to be held in Atlantic City, N. J., June 9-13, technical apparatus in use at Medical Research Laboratory, Mineola, is to be exhibited.

Papers are to be delivered on aeronautic medicine, here and abroad; films "Fit to Fly" are to be shown, and there is to be an assembly of medical men who have served at some time with the Air Service.

Aeroplane Courses Popular at City College

New York, N. Y.—Evening courses on aeroplanes and aviation engines at the College of the City of New York having met a popular demand, the authorities have decided to repeat these classes during the Summer Session commencing July first.

The enrollment in the aeronautics classes at the College during the present year has been 586 students. The laboratory equipment used in the instruction includes aeroplanes and motors donated by manufacturers and valued at $100,000.

The Summer Course, which is open to the public, will last eight weeks, and will include both lectures and laboratory practice. Those who are interested may secure further information by writing or calling at the College.

Speedy Flights by Air Service Planes

Washington, D. C.—The Air Service in official announcement reveals the following fast flights during the last week:

Handley Page aeroplane, carrying ten officers and men in charge, Capt. Clyde C. Dunnington made flight New Orleans to Houston, Texas, 362 miles, 245 minutes, completing flight from New Jersey, on June 2. The total flying time from Elizabeth, N. J., to Houston, Texas, was 1,298,-minutes, a distance of 1,525 miles.

Lieut. Gordon St. Clair, A.S.A., with a mechanician, arrived at Center City, Minn., in De Haviland from Rantoul, Ill. Flying time 387 minutes, distance 572 miles.

At a maximum elevation of 5,000 feet in a De Haviland 9-A bombing and machine-gun aeroplane, Lieut. Charles W. Miller pilot, passenger Lieut. Clifford B. Johnstone, made a non-stop flight, Dayton, Ohio, to Washington, 395 miles, in 275 minutes.

A De Haviland, driven by Lieut. W. C. Layne covered a flight to Harrisburg, Sanelon and return—54 miles, in 27 minutes.

Captain Louis E. Appleby, commanding the fliers covering Arizona on general recruiting, carried in his aeroplane from the people of Imperial Valley, California, to the Governor of Arizona a crate of cantaloupes—distance 260 miles, time 200 minutes.

Two views of the single seater "Ace" Biplane, with a 4 cylinder 40 H.P. engine, built by the Aircraft Engineering Corporation

The "Ace" Single Seater

In a recent test of the "Ace" Biplane, Pilot Bruce Eytinge, the test pilot for the Aircraft Engineering Corporation took off in less than 80 feet. He climbed to 2,500 feet in 8 minutes, and after putting the "Ace" through stunts, spiralled down and landed in less than 60 feet. The demonstration of the short stop was to give evidence of the machine's complete adaptability to small landing fields.

Pilot Eytinge is constantly "up in the air" testing and demonstrating new machines as they are turned out by the factory. The Aircraft Engineering Corporation builds both the plane and the engine, which is a four-cylinder, vertical, water-cooled, 40-H.P. engine.

Climbing tests were made on June 8th in a wind which was estimated at from 35 to 40 miles an hour. No other machines ventured aloft, but the "Ace" performed remarkably. In 20 minutes the machine climbed to an altitude of 6,000 feet. The altitude was indicated by a standard Taylor altimeter. To show its weight-carrying capacity, a test load of 180 pounds of sand was carried. In view of the fact that the machine was a single seater this reserve lift speaks well for the general efficiency of the design. Later, tests are to be made carrying a passenger, when slight modifications will be made in the seating arrangement.

In the high wind almost every aerial manoeuvre was carried out, showing the machine to be well under control at all times. With the machine headed directly into the wind the pilot could, by manoeuvring the elevators, cause the machine to slowly lift straight up or descend vertically. By throttling the engine the machine was made to remain almost stationary in the air. Upon alighting the machine came to a complete rest after a short run, which, upon being measured, was found to have been only 30 feet.

Two Air Service officers, Lieut. E. J. Spencer and Lieut. D. C. Smith, made short flights of 10 minutes each in the "Ace" to try out for themselves the stunts they had watched Pilot Eytinge perform.

London and Paris Greet Trans-Atlantic Fliers

The members of the crew of the successful NC-4 have been greeted as heroes by the cordial and generous French and British populaces. On June 5, in London, Lieutenant Commander Albert C. Read and the crew of the American seaplane NC-4, which made the successful transatlantic flight, as well as Commander J. W. Towers and the others who handled the NC 'planes, were guests at a luncheon given by Major General Seely, under secretary for air, in the House of Commons.

The luncheon was given to permit discussion of the future of British aviation. The Prince of Wales, Lord Birkenhead, the Lord High Chancellor; James W. Lowther, speaker of the House of Commons; the Earl of Reading, former ambassador to the United States; Winston Spencer Churchill, Secretary for War, and Field Marshal Sir Douglas Haig, were present.

General Seely, in proposing the health of Lieutenant Commander Read, assured him and the other Americans that "there is no trace of envy on our part for your splendid performance."

Lieutenant Commander Read in responding said:

"We want to thank you for the wonderful welcome you have given us to London. I am glad to see Commander Grieve here, and am sure Hawker would be here but for indisposition resulting from the great reception he has had.

"Our success was due to careful planning and preparations made. Flying across was the easiest part of the proposition."

The Prince of Wales in responding previously to a toast to his health, said:

"I wish to congratulate heartily Commander Read and his associates who were first to fly the Atlantic."

It was announced at the luncheon that British lighthouses soon will be fitted out to throw vertical beams to assist airmen.

The aviators had returned to London on the day previous to the banquet from Paris, where they had been in conference with Admiral William S. Benson, chief of naval operations, presumably on the transatlantic flight. Rear Admiral Plunkett, who arranged the destroyer guides from Rockaway to Plymouth, accompanied Commander Towers, Lieutenant Commanders Read and Bellinger to the Paris Conference of June 3. The party was entertained at luncheon by the American Naval Headquarters Staff.

Vickers, Vimy and Handley Page Soon Ready for Trans-Atlantic Flight

St. John's, N. F.—The news that the British dirigible R-34 may leave from England for Newfoundland within a fortnight has caused a general speeding up of work here among the transatlantic aviators. The rain which is falling almost continuously is hampering them so much, however, that the R-34 may arrive before they start.

The discovery by Captain Jack Alcott, the Vimy pilot, of a good flying field in Ropewalk, a suburb of St. Johns, was hailed with delight here by all pilots. No other entrant has a really good field, so Raynham, of the Martinsyde, as well as the Alliance and Boulton and Paul parties may use the new field. Work of clearing out rocks and other matter dangerous for aeroplanes started on June 2, but this field, too, is so sodden it is unlikely any flight can be made within ten days.

Lieutenant Arthur W. Brown, navigator of the Vickers-Vimy bomber, now preparing here for the transatlantic flight, has received word from Lieutenant Commander R. E. Byrd, U. S. N., that the Navy Department has shipped to him one of the bubble sextants designed by Liutenant Commander Byrd for the American seaplanes.

These sextants have been the envy of all the navigators who have seen them, and Lieutenant Brown expressed himself as greatly delighted and keenly appreciative of the navy's willingness to help him by lending the instrument.

The assembling has progressed so far that engine tests have begun and news of test flights is expected daily.

Wireless messages from German and Italian land stations nearly 4,000 miles away were picked up by the Hadley-Page biplane which is being assembled at Harbor Grace for a transatlantic flight. A flight in the huge Handley-Page machine to St. John's from Harbor Grace, with Vice-Admiral Mark Kerr as pilot, will be made within a few days.

Lieutenant Commander Mackenzie Grieve has refused Raynham's offer to act as navigator for the Martinsyde biplane.

Plans for Syracuse Aerodrome Under Way

Syracuse, N. Y.—The incorporation of an organization of Syracuse business men to be known as the Onondaga Aerodrome Corporation, to be capitalized at $15,000, will probably be effected at the office of the secretary of state in Albany this week. The concern will interest itself in the construction, operation and sale of aeroplanes and lighter than air machines and will be the first of its kind to take up an aerial program in Central New York on a business scale. Mr. Byron M. Burns, a local insurance dealer, is one of the several leading Syracuse business men interested in the new venture.

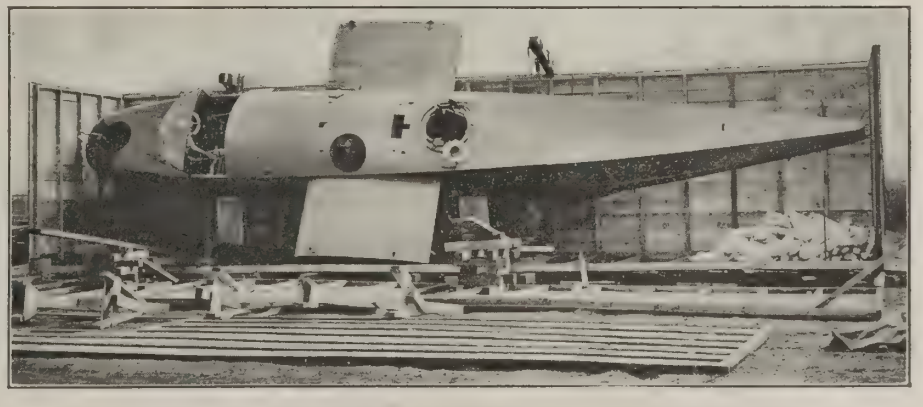
Everett Hazelton is Flying Magazine's Advertising Manager

Everett L. Hazelton, formerly western advertising manager of *The Outlook*, has assumed the position of advertising manager of *Flying*. Mr. Hazelton was an ensign in naval aviation in overseas service and he is thoroughly familiar with the technical phases of aeronautics. He also brings to his new position a practical knowledge of advertising and a definite enthusiasm for the present and future of aeronautics.

New Training and Exhibition Field Near Boston

Boston, Mass.—C. E. West, who is selling used Curtiss planes in Boston, has leased a large piece of land at Boxford, near Boston. Large hangars are to be constructed for the accommodation of his wares. He is expecting to have ten planes delivered by June 15.

Captain James Disappears in Cross Country Flight



New York, N. Y.—Captain Mansell R. James, British Ace, who left Boston for Atlantic City on May 29, has not been found. Rewards totalling $1,000 are offered for information leading to the finding of Captain James by Dr. James and members of the Aero Club of America.

An aerial search and extensive telephone inquiry have failed to reveal any conclusive information. Captain James was attempting to win the $1,000 Boston *Globe* flight offered in connection with the Second Pan-American Aeronautic Convention.

Augustus Post Addresses Second Pan-American Commercial Congress on Aerial Commerce

Washington, D. C.—The possibilities of the aeroplane in developing commerce throughout Latin America was one of the topics of the day that aroused most interest. Augustus Post, Secretary of the Aero Club of America, declared that "commercial aviation has started by leaps and bounds to exceed the tremendous development made during the time of war which put aeronautics 20 years ahead of what it would have been without this extraordinary necessity and stimulus to inventive genius." He pointed particularly to the strides of the past few months in flying across the Atlantic, and announced that the United States Army, not to be outdone by the Navy, is planning a transcontinental flight from the Atlantic to the Pacific, flying 1,500 miles without a stop before crossing the Rocky Mountains. Captain Charles J. Glidden and Captain Creston M. L. McCullough, of the U. S. Army Air Service, also spoke, the latter declaring that there would be much more activity in the future in aircraft interest in South America, and that the countries of Latin America could depend on the United States instead of Europe for their instructors and machinery.

Mr. Post spoke of actual plans now under way by the United States Post Office Department and by private concerns looking to the establishment of aerial mail routes between the United States and Cuba and the other countries to the south.

An H-16 Fying Boat hull being crated for shipment at the Curtiss plant, Garden City, L. I.

THE CURTISS MODEL 18-B BIPLANE

AFTER the successful trials of the Curtiss Model 18-T triplane, the two-seater 18-B biplane was brought out by the Curtiss Engineering Corporation. The biplane is built around the same fuselage and power plant as the triplane, but having a lesser overall height the gunner has a wider arc of fire.

The housing of the engine is particularly neat; it is entirely encased with the exception of the exhaust stacks, which are streamlined. The removable cowling around the engine makes the power plant accessible for adjustments and repairs.

As in the triplane, all interplane cables are of true streamline. Where cables cross, they are clamped together by streamlined blocks.

Another peculiarity of this machine is the employment of ailerons on the lower plane only. These ailerons are operated by steel tubes running through the lower plane and directly connected to the pilot's control stick. This principle entirely eliminates all outside control cables and rigging.

Rudder and elevators are operated by levers enclosed in the fuselage termination thereby doing away with all outside control cables. There are no external braces for the stabilizer or fin.

General Dimensions

Span, upper plane	37′— 5¾″
Span, lower plane	37′— 5¾″
Length overall	23′— 4″
Height overall	8′—10½″
Chord, upper plane	0′—54″
Chord, lower plane	0′—48″
Stagger	0′—16½″
Gap between planes	5′— 0″

Weights

	(*Lbs.*)
Weight fully loaded	3,001
Useful load	1,013

Performances

(Altitude)

	(*Feet*)
Service ceiling	22,000
Maximum ceiling	23,750
Climb in 10 minutes	12,500
Climb in 10 minutes (light flying load)	16,000

(Speed)

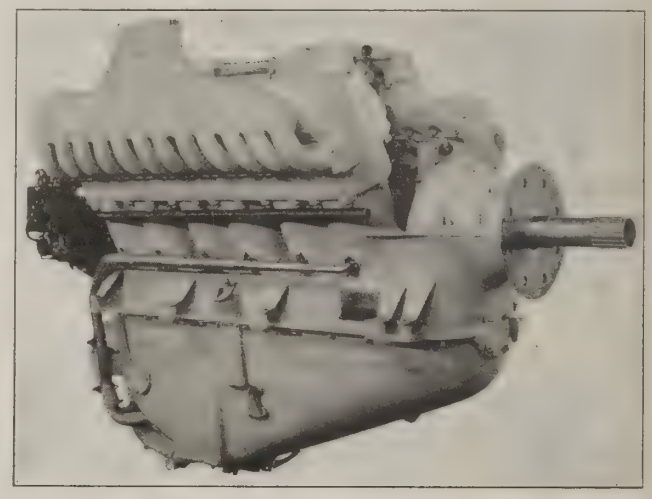
Altitude	*Sea level*	*5,000 feet*	*10,000 feet*	*15,000 feet*	*20,000 feet*
High speed (m.p.h)	160.5	158.5	157.5	155	152
Low speed (m.p.h.)	59	68.2	73.6	79.8	86
Economical Speed	80	85	92	100	118

(Climb)

Rate of climb (ft. per minute)	2390	1690	1040	580	210
Time of climb (minutes)	0	2.5	6.3	12.9	27

(Endurance)

	(*Miles*)	(*Hours*)
High speed (sea level)	283	1.75
Economical speed (sea level)	536	6.7



Main Planes

Planes are in flat span. There is no dihedral or sweepback.

Main planes are in five sections. Center section over the body 30″ wide. Outer sections 17′ 5⅞″ in span. Overall span 37′ 5¾″. Lower plane in two sections at either side of the body, each 17′ 5⅞″ in span.

As indicated on the accompanying line drawing, the ribs are spaced about 6″ apart. Instead of the usual two main wing beams, the Model 18-B employs five main wing beams, the idea being to more evenly distribute the loading on them.

The chord of the upper plane is 54″. Forward main wing beam located 9″ from leading edge. Wing beam over the rear fuselage and interplane struts 2′ 9″ from leading edge.

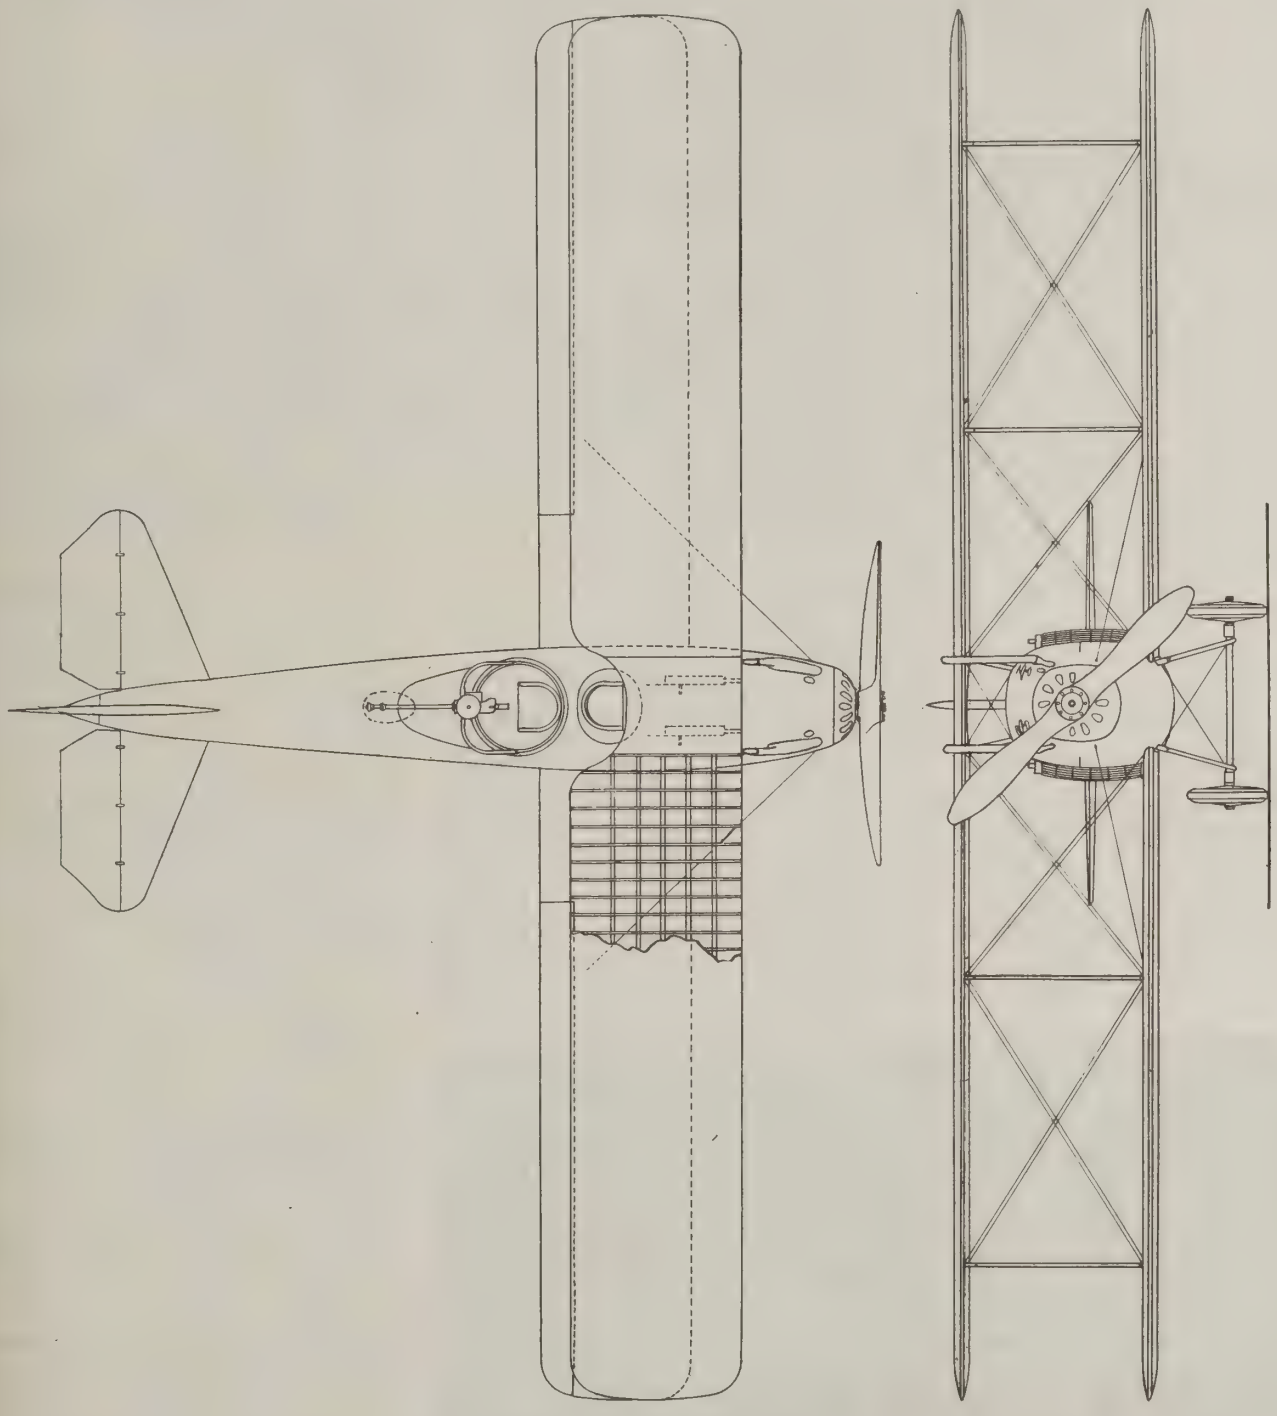
The Curtiss Model K-12 400 h.p. aircraft engine

Chord of lower plane 48″. Forward main wing beam 9″ from leading edge. From this the other main wing beam members are spaced 7 5/16″ apart.

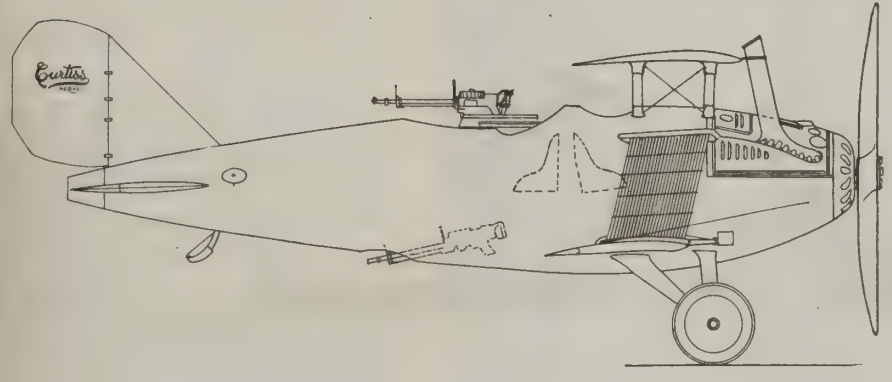
Ailerons on the lower plane have a very high aspect ratio, being 13′ 5 1/16″ in length and 10¾″ wide.

Struts over the fuselage are spaced 30″ apart. From these the intermediate interplane struts are centered 6′ 1½″. From intermediate struts, outer struts are centered 7′ 8½″. This leaves an overhang of 43⅞″.

Fuselage



The fuselage is of monocoque construction, finely streamlined. Overall length, 21 feet.



Pilot's cockpit is below the trailing edge of upper plane. Aft of the pilot, the gunner's compartment is arranged so that the gunner has a wide range of fire for the two Lewis machine guns, one of which is located on a rotatable Scarff

LYNITE LABORATORIES OF THE ALUMINUM CASTINGS COMPANY EMBODY MOST PROGRESSIVE IDEAS AND UP-TO-DATE EQUIPMENT IN THE FIELD OF INDUSTRIAL RESEARCH

THE close affinity between the aeroplane industry and the aluminum casting industry has been clearly demonstrated in the critical period through which our country has just passed. The contribution, for instance, of the aluminum castings industry to the Liberty Engine is quite generally known. Our leading aeronautical engineers are beginning to realize that the remarkable growth of the "youngest industry" has in a large measure been dependent upon the recent phenomenal advance in the arts of alloying and fabricating non-ferrous metals, and in particular, aluminum with copper and zinc. It is therefore of apparent interest to aeroplane builders to assure themselves that the aluminum castings industry of the United States is not only doing some real constructive work which will enable it to keep pace with the present demands of aeroplane manufacture, but also is fully prepared to meet the certain further expansion of aerial activities.

In order to meet the increased demand for better aluminum alloys as materials of construction in all branches of industry, including aeroplane manufacture, The Aluminum Castings Company, the world's largest producer of aluminum castings, created in the summer of 1915, a special research and development laboratory, which to-day is known as Lynite Laboratories.

The general organization of these Laboratories is laid out on broad and comprehensive lines, to include:

(1) Research along purely scientific lines in the arts of alloying and fabricating non-ferrous metals;
(2) The adaptation of this scientific knowledge by means of experimental and development methods; and
(3) The scientific control of foundry practice to insure the desired results.

Beginning in a modest way as a department of The Aluminum Castings Company, with a personnel of a single scientist and a works laboratory of a single room in an office building, Lynite Laboratories to-day maintains a staff of over one hundred trained specialists, and occupies 22,000 square feet of floor space, in a building erected for and devoted entirely to research. It is equipped with modern apparatus of wide range and completeness for research and development work. Lynite Laboratories also directs the activities of the commercial testing and control laboratories in the company's various plants.

The scope of the organization plan of Lynite Laboratories, conceived as it was when the research idea was fairly new, has met with much favorable comment on the part of research authorities throughout the United States. Its breadth of plan, based on far-sighted vision, is particularly appreciated in the light of the proposed specifications for the ideal research organization submitted to the Institute of Metals in London only a few weeks ago by no less an authority than Walter Rosenhain, its vice president. This eminent scientist now urges the adoption by the British Non-Ferrous Metal Industry of a research plan* which is as striking as it is identical with the organization of Lynite Laboratories. As a further indication of how completely the British authorities are convinced of the necessity for scientific research as developed in this country and illustrated by Lynite Laboratories, the British Government has just voted to place at the disposal of industrial research the huge sum of £1,000,000 sterling.**

THE METALLOGRAPHY LABORATORY

In the foreground is the potentiometer for precise temperature measurements. It has a sensitivity of .0000001 of a volt. The micro-structure of aluminum alloys is studied through the metallographer's camera in the left-hand corner. The specimen is carefully polished and etched and then placed on the stage of the microscope. The carbon arc lamp on the bench at the right is for illuminating the object

Lynite Laboratories

Lynite Laboratories comprise the following sections:

RESEARCH DIVISION.

1. *Metallurgy Section,* for the investigation of foundry melting practice and the study of the processes of alloying, refining and purification of metals and alloys.

2. *Metallograph Section,* for the determination of the constitution of metals and alloys and the study of the relation of their thermal and mechanical treatment to the constitution and physical properties.

3. *Chemistry Section,* for the analysis of the materials of construction, the maintaining of standards, and particularly alloy development.

4. *Physics Section,* for the investigation of special physical phenomena relating to the company's processes and products.

5. *Tests Section,* for physical tests of alloys, special mechanical tests, heat treatment, production of test bars and special melting tests.

DEVELOPMENT DIVISION

1. *Dynamics Section,* for theoretical investigations and tests to determine design constants for internal combustion engines and their various component parts.

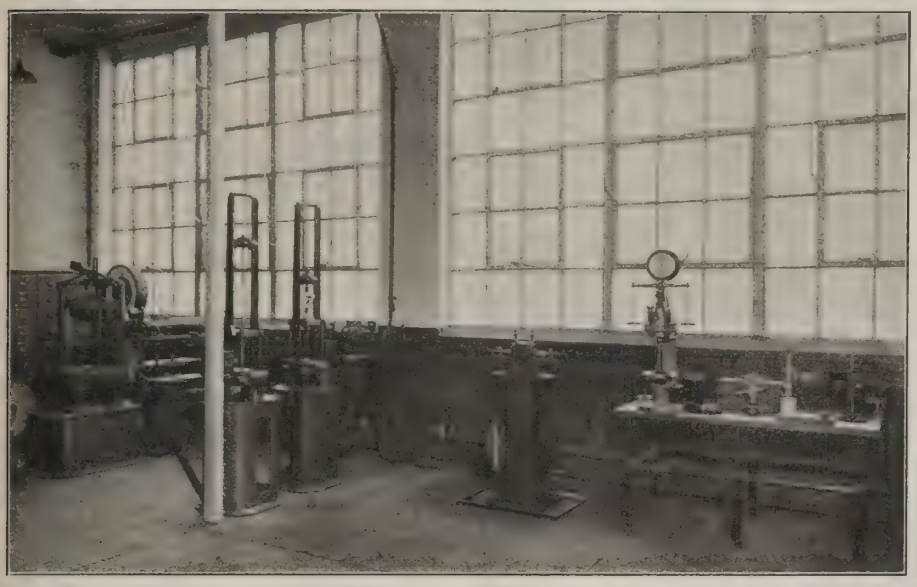
2. *Engineering Section,* for general designing, drafting experimental construction, apparatus construction.

3. *Automotive Engineering Section,* for special automotive design service in engines, pistons, chassis, wheels, etc.

4. *Permanent Mold Section,* for sample production by permanent mold as well as general experimental work for improvement of the process.

5. *Sand Castings Section,* for sample production by sand casting as well as experimental foundry practice in core making, molding and melting.

TECHNICAL CONTROL.



1. *Technical Standards Section,* for technical control of foundry and alloy practice.

An Open-Minded Organization

Before taking up a detailed discussion of the work and equipment of the several sections, a general understanding of the distinct principles upon which Lynite Laboratories was founded should be borne in mind. In the first place, its organization is an open-minded one, in which the specially trained minds in the

* NOTE: Dr. Walter Rosenhain, F. R. S., Vice President of the Institute of Metals, Superintendent of the Metallurgical Department of the National Physical Laboratory, etc., presents his plan for the ideal research organization as applied to the non-ferrous metal industry in *Engineering*, March 28, 1919, Page 422.

** *Chemical and Metallurgical Engineering*, April 15, 1919, page 399.

BATTERY OF MACHINES FOR TESTING PHYSICAL PROPERTIES

The above photograph (reading left to right) shows three tensile testing machines, one of which is operated by hand; an alternating stress machine; a Brinell hardness testing machine, and a sclerescope, also for hardness tests.

Fig. 1—The White Souther Alternating Stress Machine—To determine the ability of a material to resist fatigue loading, a test bar ½" in diameter is rotated at a speed of 1326 r.p.m. A load is applied by means of a spring balance through ball bearings at the end of the specimen, which causes a slight bending. Each time the specimen rotates the stress is reversed. Thus a particle which was in tension at the top of the specimen, after one-half turn, reaches the bottom and is put in compression. The load applied is varied from 20 to 50 lbs., so that the time required to break an aluminum alloy test bar varies from one day to a month or more

various sciences pertaining to the Company's products are co-ordinated under the direction of an administrative mind. This mind is also the point of contact between the Laboratories and the rest of the Company. Every member of the Laboratories organization is impressed with the fact that ideas control markets, and that the company's future depends upon its keeping in advance of the present development of each art or science with which it is concerned. It is held of first importance that the organization be as free as possible from outside influence or the obsessions of any of its members; that each member be free to express his ideas having to do with his particular work, and at appropriate times to express all his ideas with respect to the operation, development and organization of Lynite Laboratories. Ideas of every description,—good, bad, and indifferent,—are thus collected, sorted and classified.

For an idea to receive the attention of the Lynite Laboratories staff it must become a formal problem. Before it can become a formal problem, it must pass the critical scrutiny of a Problem Committee, which includes the heads of various sections of the Laboratories, as well as executives of the company itself.

Supposing the idea has passed this first acid test and has become a formal problem. It is now necessary to determine its status, for nothing must be done that has already been done. Accordingly, all existing information bearing on the problem in any way, whether resting in the files of the Patent Offices, in technical publications, in text books, in the minds of men, or in the library of Lynite Laboratories, is systematically collected, classified and carefully studied. When this has been done, it is quite possible our young and promising problem may be ruthlessly thrown in the discard. If not, it is quickly labelled "urgent," "important," or "common," as necessities of the occasion dictate, and assigned to its particular section or sections, where it is carried along with the utmost speed consistent with its classification until the happy day when it shall be voted "closed."

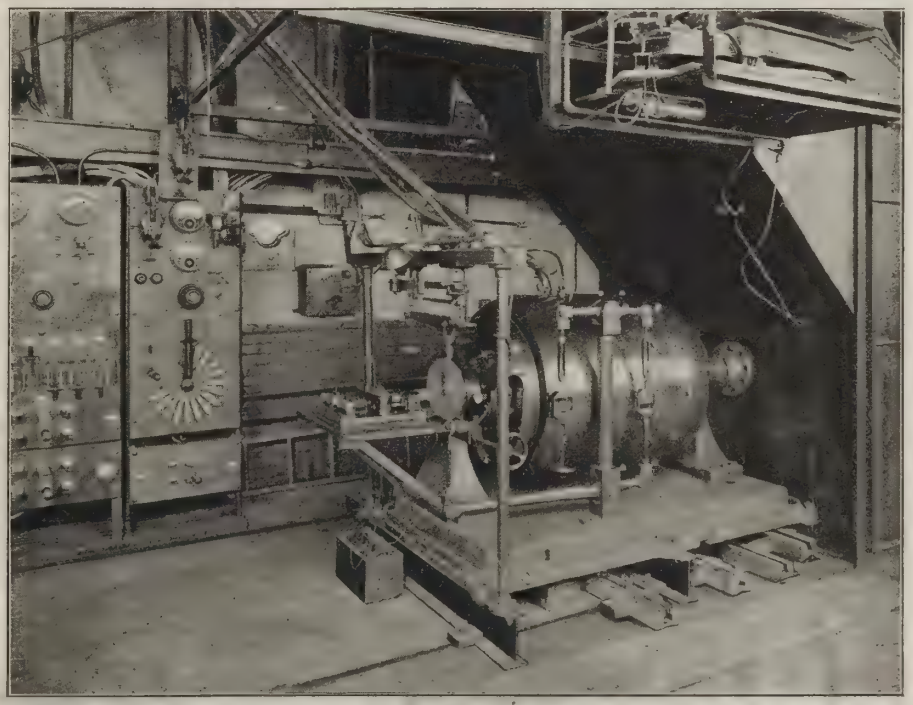
Research Division

The Division of Research embraces all investigations in the realm of pure and applied science, and is predicated upon the fact that scientific research implies sound reasoning, the ability to marshall facts, and by correct analysis, both elemental and general, arrive at correct conclusions. The division itself comprises the various sections listed above, and works in close co-operation with the Development sections.

Metallurgical Section

The work of this section includes all general metallurgical research not included in the special research field. It consists of a broad study of alloy development and in particular a field investigation of melting practice and improved metallurgical methods.

Chemical Laboratories



There are two distinct phases of the work of the Chemistry Section, namely: test and research. The exact control necessary to successful operation and research is rendered possible by the chemical testing laboratory. Here is the personnel and equipment necessary for the complete analysis of aluminum alloys, bronzes, and other metals. The everyday question of corrosion and the action of alloys under new conditions, such as heat treating, are answered here, as well as all routine work connected with research.

It has full facilities for small-scale research and includes in its equipment everything in the way of furnaces, hot plates, glass blowers' bench, balance room, fume cabinet, etc.

The research activities are best seen in the special experimental and development laboratory. This laboratory is the stepping stone from the test tube and beaker to plant production. It is an admirable workshop, fully equipped with motors, tools and specially constructed apparatus designed to meet the needs of industrial research work.

Metallography Section

The rapid advance in the arts of producing, fabrication and alloying of metals in the last twenty years has been very

WEIGHING SYSTEM OF DYNAMOMETERS

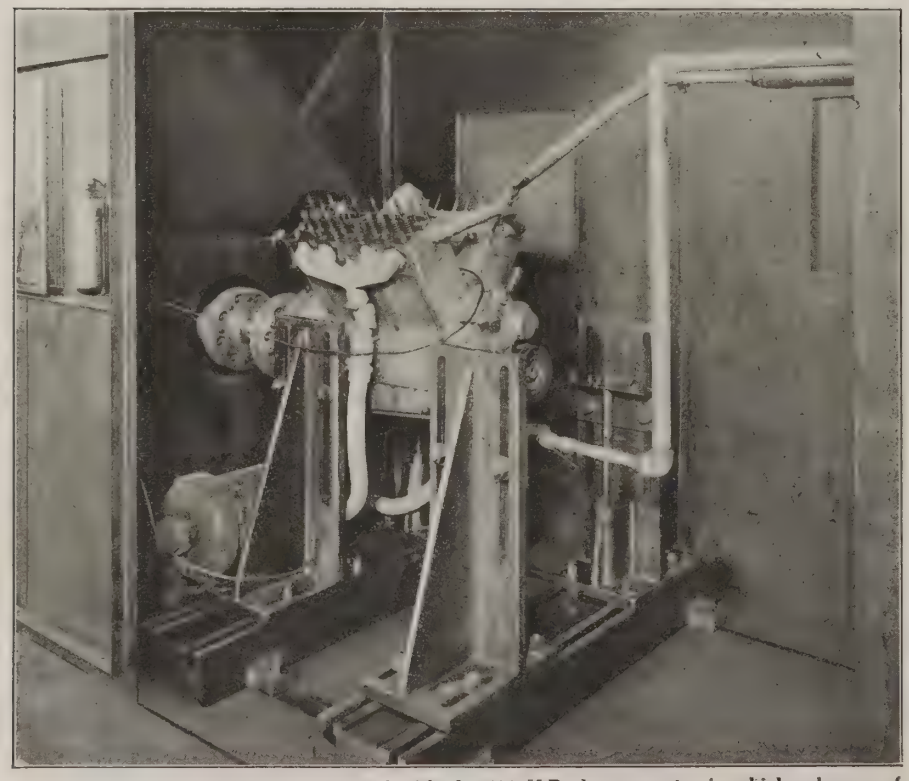
This system was specially designed and built for Lynite Laboratories. It embodies a multiplying lever, so that the scale reads the pounds torque at a 63-inch arm and makes horse-power calculations very easy. Most of the knife-edges have been dispensed with, and self aligning ball bearings used in their place. The whole system is so delicate that if a quarter-pound weight be placed upon the knife edge on the dynamometer field frame it will show a deflection on the scale

A corner of the Laboratories' own machine shop

largely due to the development of the science of metallography. Briefly defined, metallography is the study of the "constitution" of metals. Just as the doctor investigates a wound in the human body or probes into the vitals themselves, so the metallographist goes beneath the surface of metals, examines their structure and determines their "constitutional characteristics." Many methods are applied in this "humane" work, the most fruitful of which have been thermal and microscopic analyses. Accordingly, the equipment of this section includes a metallographic camera for taking microscopic photographs; a large camera for photographing objects at their actual size; electric furnaces and a special potentiometer for heat treating and cooling curve work, and apparatus for the determination of the coefficient of thermal expansion and the thermal conductivity of alloys.

Physics Laboratory

Appreciating the necessity for physics research to round out the scientific investigations of the Laboratories, a separate section has been created to study the various problems from this point of view. The equipment consists of voltmeters, potentiometers, ammeters, condensers, galvanometers, resistance standards, Wheatstone bridges thermometers of all types, telescopes, and all necessary apparatus for making measurements. The work of this section is essentially research in its character, and therefore calls for special apparatus which is designed and built as needed. In order to maintain close contact with foundry practice, the organization includes an industrial physicist.



The Tests Section

The Tests Section comprises a test bar foundry and a physical testing laboratory. The work of the foundry consists in the production of test bars, by which the properties of the new alloys may be studied, and also in study of the effect of variation in melting and casting practice. Two oil-fired crucible furnaces are used for melting, while two gas-fired furnaces, one for high temperatures and one for low temperatures, are available for experimental heat treatment.

Fig. 3—CHARPY SINGLE-BLOW IMPACT MACHINE

The use of this machine in the non-ferrous industry is new. A square bar about ⅜" on a side, notched at the center, is supported over a 2" span. The falling pendulum fractures the test bar in one blow. The energy absorbed is measured by the difference between the original energy of the pendulum and the energy remaining after the blow, which is indicated by the height to which the pendulum rises. It delivers a blow of 200 ft. lbs., or the equivalent of a weight of 40 lbs. falling through 5 feet

Here is the large wind tunnel connected with the 400 H.P. dynamometer in which a breeze of 40 miles an hour can be blown past the engine. On the block and ready for test is shown a six-cylinder all-aluminum engine

The work of the physical testing laboratory is both routine and special, according to the nature of the problems with which it is concerned. Under routine tests would be classed the usual tension tests, by which the yield point is determined as well as the maximum stress and elongation. Other properties which may be determined are the reduction of area, elastic and proportional limits and modulus of elasticity—all of which have a very important bearing on the use to which the alloy may be put. There are no less than four tensile testing machines, with a capacity from 10,000 to 200,000 pounds, thus insuring tests on a wide range of work. Take for ex-

ample the 50,000-pound machine. This machine will take a standard test bar of a material having a maximum stress of as high as 250,000 pounds per square inch. The 200,000-pound testing machine is used in making tests on large aluminum castings.

There are two standard ways of measuring hardness. One is by microscopic examination of the depth to which a hardened steel ball is forced by pressure upon the alloy under test. This is the Brinell test. Here a ten mm. steel ball is forced into the metal by hydraulic pressure. For soft metals, a pressure of 500 kg. is used, while for hard metals 3,000 kg. is necessary. The diameter of the indentation is measured by means of a microscope from which is calculated the Brinell hardness number. This value is read directly from tables, and represents the load in kg. per square mm. of spherical area of the indentation. The other method of determining hardness is by means of the rebound of a small hammer. The instrument used is known as the scleroscope. It consists of a hammer which falls from a fixed distance inside a glass tube. The height of the rebound of this hammer gives the scleroscope hardness.

Another physical test, not as common as those mentioned but of considerable importance in certain cases, is the transverse test. A standard bar is supported at two points, say 12 inches apart, and a load applied in the center. The testing machine weighs the load applied, and measures the deflection of the test bar.

Compression, or the ability of a material to resist "push," is also measured in the tension testing machines.

The special tests include fatigue and impact tests, as well as tests on fabricated parts. In the impact field the Stanton Repeated Blow Impact Machine is of particular interest. It is an English machine, and very popular with British engineers. The test tells how the material will stand up under repeated blows in actual operation. Fig. 2.

The Charpy Single Blow Impact Machine is of French inheritance. A falling pendulum fractures the test bar in one blow. Fig. 3. This machine has wide use in steel testing, but its application to non-ferrous metals is radically new and of considerable significance.

The White-Souther Alternating Stress Machine shows how a material may resist "fatigue," for metals seem to tire just as human beings do. Fig. 1.

The Dynamics Laboratory

The Dynamics Laboratory occupies a room about 110 feet long and 25 feet wide. Its work consists of theoretical investigations of internal combustion engines, and in particular, study of such parts as use aluminum alloys. It conducts all tests for establishing principles used in design, and includes routine tests to determine piston and cylinder wear and the general testing of gear wheels and rear axles. The principal equipment consists of three Sprague dynamometers:

One rated at 400 H.P. at 1400 r.p.m.
One rated at 200 H.P. at 1350 r.p.m.
One rated at 100 H.P. at 1200 r.p.m.

In installing this equipment, the customary bed plate was not used, but instead a special channel construction was embodied in the concrete floor to which the dynamometers could be bolted. This gives the equivalent of a bed plate extending the entire length of the room. The advantages of this are apparent. The dynamometers can easily be moved around to any position on this space, and two or more can be connected in tandem, which makes it possible to test an engine whose power output is greatly in excess of the capacity of any one individual dynamometer.

VIEW OF DYNAMIC LABORATORY

showing three Sprague Electric Dynamometers, Alden Absorption Dynamometer for rear axle tests, and generators. Note the channel construction in the floor, giving a bed plate extending the length of the laboratory, and also the amount of floor space available due to the overhead location of apparatus and devices

Another advantage of embodying the bedplate in the floor is that the length of the engine or other piece of apparatus which is being tested is not limited by the length of the bedplate. This is especially advantageous in a laboratory in which a great variety of work must be done, and where the testing is not limited to engines of one size.

The weighing system of the dynamometers was especially built for the Lynite Laboratories. It embodies a multiplying lever, so that the scale reads the pounds torque at a 63-inch arm. This makes horse-power calculations very easy. In this weighing system, most of the knife edges have been dispensed with, and self-aligning ball bearings used in their stead. The whole system is so delicate that if a quarter-pound weight be placed upon the knife edge on the dynamometer field frame, it will show a deflection on the scale.

The revolution counting device was also especially built for this Laboratory. It consists of two Veeder counters con-

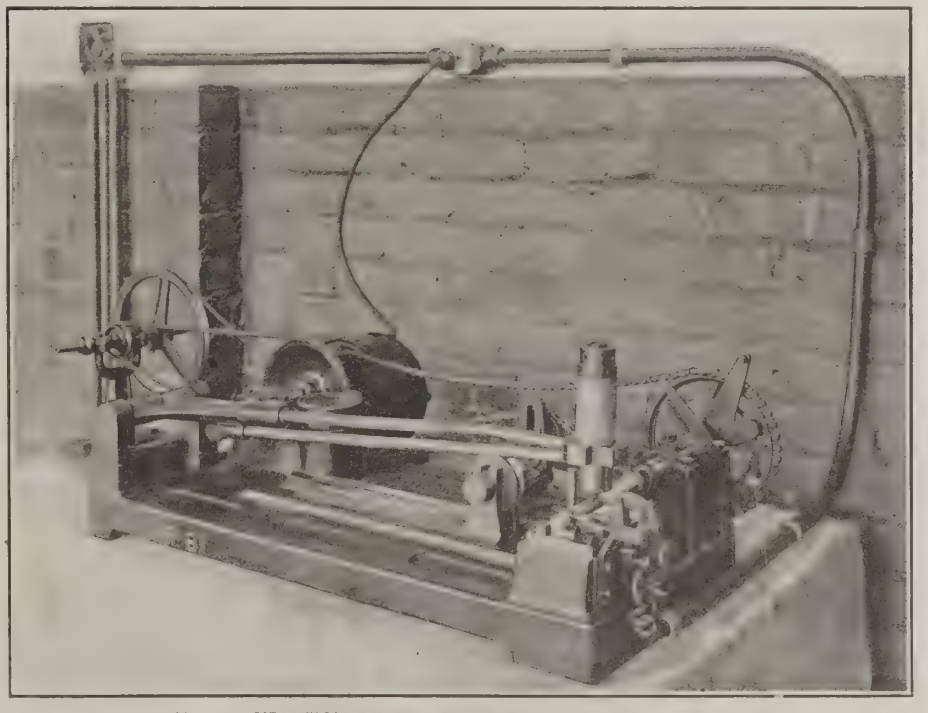


Fig. 2—STANTON REPEATED BLOW IMPACT MACHINE

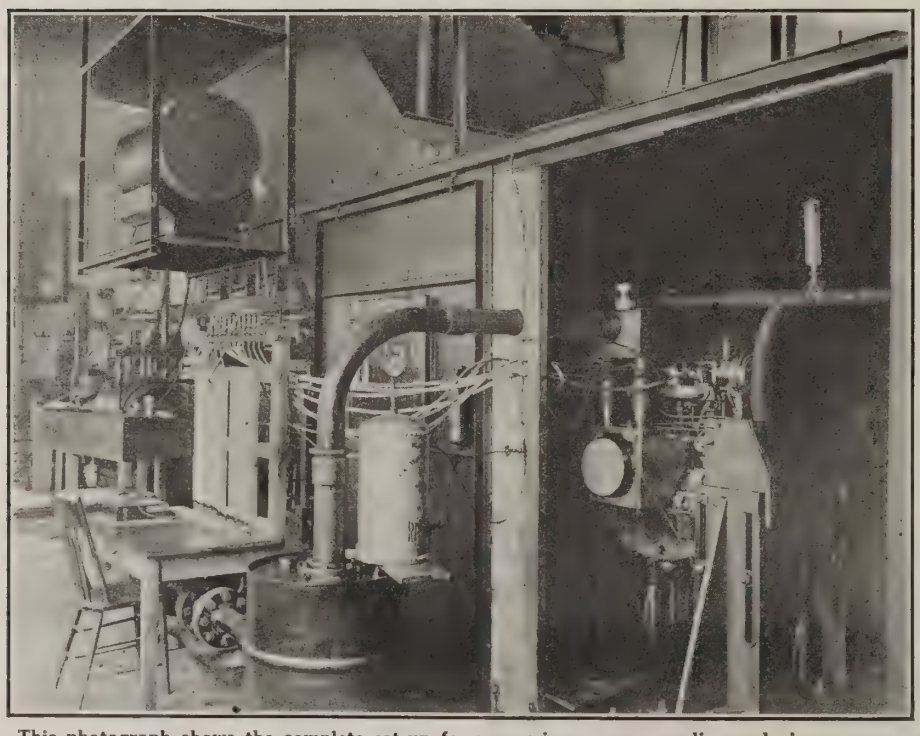
This machine tests the ability of material to withstand repeated shock. The specimen ½-inch in diameter is supported by knife edges 4½ inches apart. A hammer weighing approximately 3 pounds is dropped upon the center of the bar, which rotates so that the second blow hits 180 degrees from the first. These blows are repeated at the rate of 100 per minute. The height of the fall of the hammer may be varied up to 4 inches, so that the test bar may be broken in one blow, or require a week or two weeks of continuous operation before fracture takes place



Testing laboratory of the Chemistry Section, showing balance room, fume cabinet, etc.

nected through a gear box to the dynamometer shaft. These counters are provided with a jaw clutch which can be thrown in and out electrically. The wiring is so arranged that when one counter is thrown in, the other one is thrown out. Readings can therefore be taken at regular intervals without losing the total count.

The flexible couplings were all built in the Laboratories' own shops, and consist of two flanges, one connected to the engine, and one to the dynamometer, and an intermediate piece connected through leather discs to each of the other two flanges. So that the leather may not be called upon to carry the weight of the intermediate piece, this piece is supported on spherical protections centered in the discs connected to the engine and the dynamometer. The leather, therefore, transmits only the torque. Several of these couplings are made of Lynite castings.

In connection with the 400 H.P. dynamometer, there is installed a wind tunnel, so that the engine under test may be placed in a breeze varying from 35 to 40 miles an hour. In this case it is not necessary to connect the exhausts of the separate cylinders to a manifold. The breeze can blow out the exhaust quite easily. The operation of the engine can be observed through windows. When making long endurance tests of engines, it is also desirable to use this wind tunnel for keeping the engine at a reasonable temperature.

This photograph shows the complete set-up for measuring power, gasoline and air consumption, as well as for determining temperature in each exhaust pipe and pressure in the inlet and exhaust pipe for each cylinder

The fuel is contained in a tank mounted on a delicate scale and fed to the engine by gravity. Weighings are made over as long a period as possible, rarely less than two minutes, depending somewhat, of course, upon the size of the engine and the speed at which it is running. At least three readings are taken.

The air consumption of engines can be measured by the use of Venturi meters. The laboratory possesses various sizes of such meters, and the necessary expansion and deadening chambers to go with them. Having measured the air and the fuel, the mixture ratio of course can be calculated, and their measurement is of no little importance in studying the performance of an internal combustion engine. The air measurement of course is also used for determining the volumetric efficency.

On its way to the engine, the cooling water passes through a Venturi meter, which measures the rate in pounds per minute. The temperature of the ingoing water is kept constant by the use of a thermostat. Both in-going and out-going cooling water temperatures are measured with mercurial thermometers.

The heat loss in exhausts can be measured in a calorimeter. In making this measurement, the exhaust gas is passed through water, and the increase in temperature of the water as well as the quantity is noted. This apparatus must generally be built to accommodate the size of the engine. All the parts, however, entering into its construction are included in the apparatus of the laboratory.

The work of the dynamics laboratory is not limited to making tests of internal combustion engines. Gears, rear axles, etc., are also included in the work done in this department. For this reason the laboratory is also equipped with the Alden absorption dynamometer. This is for use in absorbing power at extremely low speeds, such as is necessitated in making tests of rear axles.

Since it is impossible to purchase direct current, it is necessary to make it. For this purpose two motor generator sets are employed. One, at 10-K.W. 120-volt D.C., is used for exciting the dynamometer fields and supplying small quantities of direct current to the other laboratories, such as the chemical and metallographical. The other one is a 150-K.W. set, and converts 400 volts 3-phase alternating current to 250 volts direct current, for running the dynamometers. Although it means extra and expensive equipment, there is a considerable advantage in generating the direct current rather than purchasing it. This advantage consists in the fact that the voltage is controlled. Very frequently it is desirable to supply a dynamometer with lower voltage current so as to get slower speed when operating the dynamometer as a motor. When current is purchased from the outside, speed must be reduced by inserting armature resistance. This is more or less difficult, but if the current is generated within the plant, you can merely reduce the voltage on your generator.

The arrangement of the electrical switchboards has been worked out to make them accessible and keep them as safe as possible. The incoming leads carry 440-volt 3-phase alternating current. The direct current is distributed through the laboratories from the panel placed between the control panels for the 200 and 400 H.P. dynamometer, as is shown in the illustration. For convenience, receptacles carrying both alternating current and direct current have been

conveniently located around the walls of the laboratory. Also high and low pressure air outlets, as well as gas, are conveniently located.

The laboratory is well equipped with apparatus for standardizing thermometers and gauges. This is kept in operating condition so as to minimize the amount of work necessary to calibrate a gauge or a thermometer, and thus encourage making such calibrations at frequent intervals.

Much attention has been given to the method of recording observed data. Four data sheets are used, and are designated as "a," "b," "c," and "d." Sheet "a" contains spaces for the observations in making all power measurements of an engine. Sheet "b" is especially arranged for recording data relative to fuel consumption, cooling water, and lubrication. Sheet "c" is suitable for recording information relative to the air consumption and exhaust measurements. Sheet "d" is a blank sheet, divided into columns, and is intended for use for special tests. Besides providing space on Sheet "a" for recording power observations, space has also been provided for putting down calculated results and for transferring results from Sheet "b."

This section has developed a very complete set of data sheets upon which are recorded the results of all tests, including graphic charts and drawings.

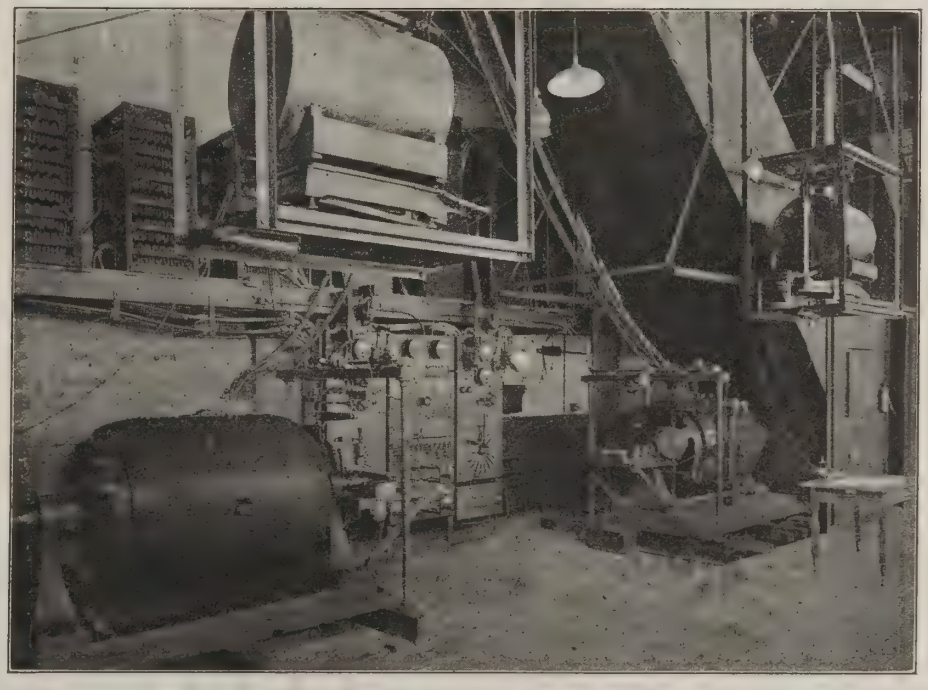
Development and Experimental Division

Under this heading comes the second group of workers employed in scientific research. Theirs is the duty to utilize the knowledge of science and by experimentation to put new products or processes into production. They may be called "the adapters." The relation between this division and that of the Research Division, as well as technical control, which is briefly referred to below, is very close and often overlaps, so that it is sometimes difficult to place a certain type of work entirely in any one division.

General Enginering and Automotive Enginering

These are two separate and distinct sections, though of course closely correlated. Experimental and development work requires an outfit of machinery and tools having the minute accuracy of the specialized tool room, and at the same time the range and adaptability of the contract shop. Accordingly, the General Engineering Section is provided with a full line of tools and machinery to meet these extraordinary demands. Its work calls for the building of special aparatus and machinery for experimental purposes, the machining of specimen bars for various tests, and the repairing of all apparatus of the laboratories that calls for machine work, from the microscope to the dynamometer. It has its own drafting and designing corps and keeps its own special drafting records and files.

Due to the expansion of the automotive industry, it has been considered necessary to have a special staff of experts to devote their entire time and effort to design and engineering in this field. This section is concerned with all theoretical principles of design involved in the evolution of the automobile. It further includes experts in the various special branches of automotive design, particularly motor car and aerial engines. It is further specialized to include experts on the various parts of those engines, such as the piston, the cylinder, the connecting rod, and other parts that may be made of aluminum alloys or involve the use of them.



The Process Sections

The Permanent Mold, and Sand Casting Sections may be classed under the above heading for the sake of brevity. Each of these sections is concerned with experimentation and development work in a specially assigned field. Not only new processes, but new products are the fruits of these sections. Here is where the ideas converted into formal problems by the Problem Committee, after thorough scientific study and test in the other sections outlined, are actually put into tangible form. From here the new processes or products go into production.

These Sections exist as complete departments, with their own special foundry equipment and machinery complete. As in every other section of Lynite Laboratories, each section is directed by one man and has its own special organization, all supervised by a director of development, corresponding to the director of research, both of whom are responsible to the manager.

Technical Control

This is the third large division into which The Aluminum Castings Company divides its research organization. Its activities are controlled by the director of research. Its work is to regulate and improve foundry practice in all the company's plants. It supervises ordinary routine technical control conducted through laboratories connected with the individual plants, but devotes the greater part of its effort toward the extension and improvement of technical control policies, the introduction of new processes, and the maintenance of foundry standards.

This is a close-up of the 200 H.P. and 400 H.P. Dynamometers, showing their respective control panels on the switchboard. Direct current is distributed throughout the rest of the Laboratories from the panel in the center

OFFICIAL STORY OF C-5 DIRIGIBLE'S RECORD FLIGHT TO NEWFOUNDLAND

THE Navy Department has made public the official report of Lieutenant-Commander E. W. Coil on the recent flight of the naval dirigible C-5 from Montauk Point, Long Island, to St. John's, Newfoundland, a distance of 1,022 nautical miles. The report emphasizes the fact that it was not due to any lack of precautions that the C-5 was lost from her moorings.

After describing in detail the preliminary work the report says:

"Start was made from the naval air station, Montauk, L. I., N. Y., at 8 a.m., May 14, 1919. Departure was taken from Montauk Point and course laid for the naval air station at Chatham, Mass., which point was passed over at 10:10 a.m. Air conditions at the time of start were generally excellent. A southwest wind of 18 miles an hour was blowing. A light haze prevailed. No particular incidents of interest occurred in this part of the trip. Everything about the C-5 was functioning properly, engines running at 1,100 revolutions a minute.

"After passing over the naval air station at Chatham course was set for Cape Sable, taking departure from Chatham. The course was checked by a series of bearings of points on shore and compass error found by azimuths of the sun. Due to haze visibility was not very good. Landfall was made on the southwest coast of Nova Scotia, about 20 miles north of Cape Sable, at 2:30 p.m.

Rough Weather Encountered at Nova Scotia

"The passage from Chatham to Nova Scotia was smooth and without incidents out of the ordinary. After sighting the coast of Nova Scotia course was set to cross overland to the eastern coast of Liverpool. During this passage extremely rough air conditions were encountered, the C-5 yawing, diving and climbing at all angles.

"Every part of the structure was subjected to strains of the severest possible nature in the air, but no failures of any kind occurred. In one sharp dive of about 400 feet the tail fin nearly struck the ground, the C-5 answering her controls just in time to avoid a smashup.

"The east coast of Nova Scotia was reached at Liverpool at 3:45 p.m., where the C-5 passed to sea for a distance of about 10 miles and course was held along the coast of Nova Scotia. Air conditions even over sea were rough and steadily becoming worse. The wind was increasing and shifting toward west. Past abeam of Halifax at 5:10 p.m.

"The sky was overcast and darkness prevailed. Air conditions were growing worse and some difficulty was experienced in holding the C-5 to her course. A rain squall was encountered at 10 p.m. and lasted until 10:45 p.m.

"At 11:15 p.m. passed over Scutari Island,

(*Continued on page 702*)

THE FARMAN TOURIST AEROBUS

THE first civilian passenger service flight between the French and Belgium capitals was inaugurated March 27th, when one of the Farman Type F-60 Tourist Aeroplanes left Tousses-Le-Noble near Paris. On May 6th, the Goliath ascended to an altitude of 5,100 meters (16,732 feet; more than three miles), carrying twenty-five passengers. This altitude was reached in one hour and 15 minutes; the descent was made in 25 minutes.

This huge tourist aero bus was built to acommodate twenty passengers. Its size has suggested the name "Goliath," the name by which the F-60 machine is now popularly known. On the first flight the distance each way was covered in less than three hours. It is expected that service between the two cities will be weekly until further notice.

The forward part of the fuselage is provided with comfortable light wicker chairs and many accommodations for the aero tourists. The pilot's compartment is open at the top permitting the necessary unobstructed vision, but the remainder of the fuselage is entirely enclosed, with windows on the sides.

Dimensions

	(*Meters*)	(*Feet*)
Span, upper plane	28	91.86
Span, lower plane	28	91.86
Length overall	14.750	48.39
Height overall	5	16.4
Chord, both planes	3.06	10.25
Gap between planes	3	9.84

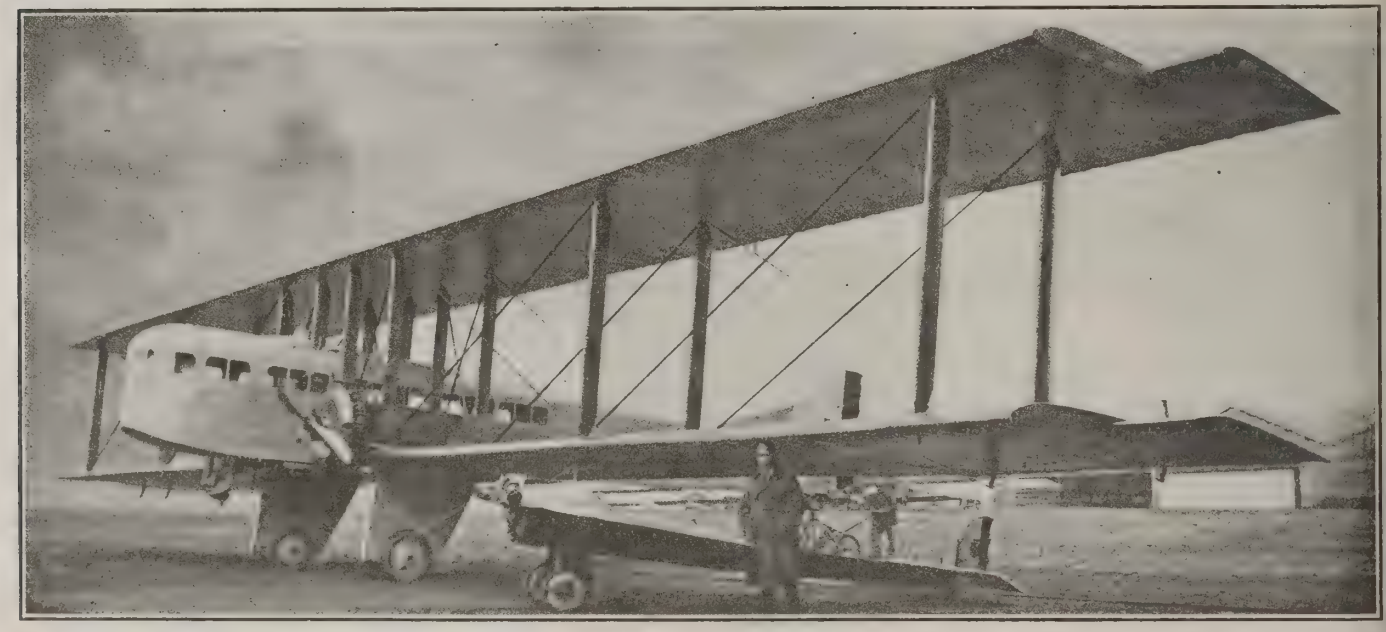
Weights

	(*Kgs.*)	(*Lbs.*)
Weight, empty	2,000	4,409.24
Useful load	2,000	4,409.24
Fuel	520	1,126.24
Total load	2,530	5,555.64
Weight fully loaded	4,520	9,964.88

Performance

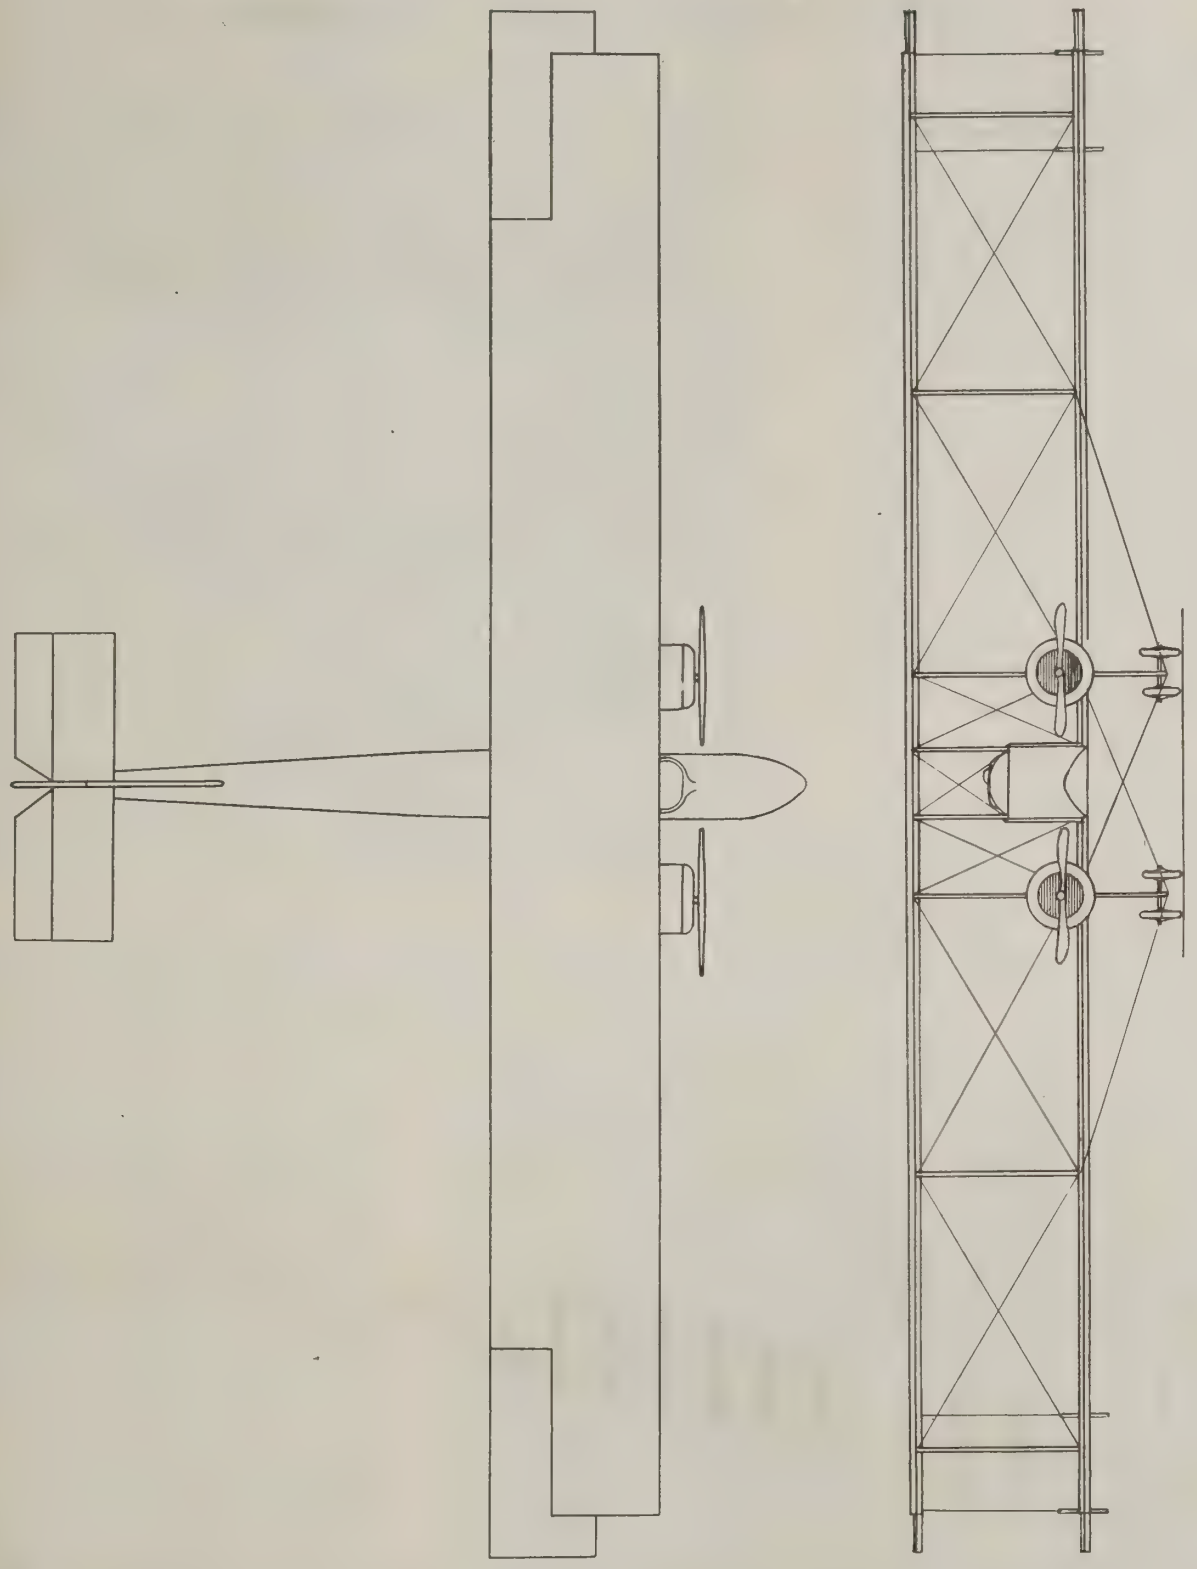
	(*Km.*)	(*Miles*)
Maximum speed, per hour	160	99.44
Minimum speed, per hour	60	37.00

(*Time of Climb*)	(*Altitude*)
4 minutes	1,600 feet
10 minutes, 30 seconds	3,200 feet
17 minutes	5,000 feet
25 minutes	6,500 feet

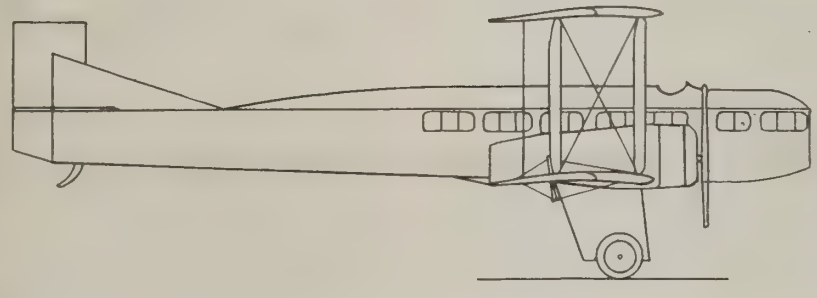


The upper and lower planes are similar in outline and area. Area of both planes is 164.89 sq. m. (1,775 sq. ft.). Center struts running up from the fuselage are spaced 1.328 m. (4.3 ft.) apart. From these struts, interplane struts behind the engines are spaced 1.336 m. (4.37 ft.). This spaces the engines 4 m. 13.12 ft.) apart. The landing gear struts are located below the engines.

From the engines, intermediate and outer interplane struts are located 5 m. (16.4 ft.). The overhang, not including ailerons, is 1.25 m. (4.09 ft.). Ailerons are 3,760 m. (11.44 ft.) long; width, 1.065 m. (3.35 ft.). The ailerons are of the balance type and at the balanced portion they are 1.875 m. (3.38 ft.) in width.



The tail unit is 5.500 m. (18.04 ft.) in overall span. Stabilizer, 1.100 m. (3.6 ft.) wide. Elevators are .800 m. (2.62 ft.) wide.



The rudder is 2.500 m. (8.2 ft.) in height. It is of the balance type. Average width .750 m. (2.46 ft.) Width at the balanced portion 1.250 m. (4.09 ft.). The fin extends 4.040 m. (13.24 ft.) forward of the trailing edge of the rudder.

The engines used are Salmson 9 cylinder "Star," each giving 260 H.P. Fuel consumed at the rate of 104 pounds per hour.

The two extremes: The twin-engined 520 H. P. Farman "Goliath" Type F-60 Tourist Aerobus with a wing spread of 92 feet, contrasted with a Farman Monoplane, called the "Mosquito," which has a wing spread of 17.7 feet and a 40 H. P. engine. The "Goliath" makes a speed of 99 M. P. H. and the Monoplane a speed of 62.15 M. P. H.

THE COSMOS AERO ENGINES

THE last half of 1918 saw the end of several things besides the war. One of them was prejudice against and objections to radial engines. In fact, November 11 saved the poor Hun from more than one unpleasant aerial novelty, and in particular from the forthcoming results of the development of some new engines of this type.

Rotaries have for some time been humming their swan song, but the stationary radial has taken on a new lease of life. Dilation on the good points of this type of engine is unnecessary, but it is only recently that engines have come into existence wherein the good points of the type have not been obscured by bad design or workmanship.

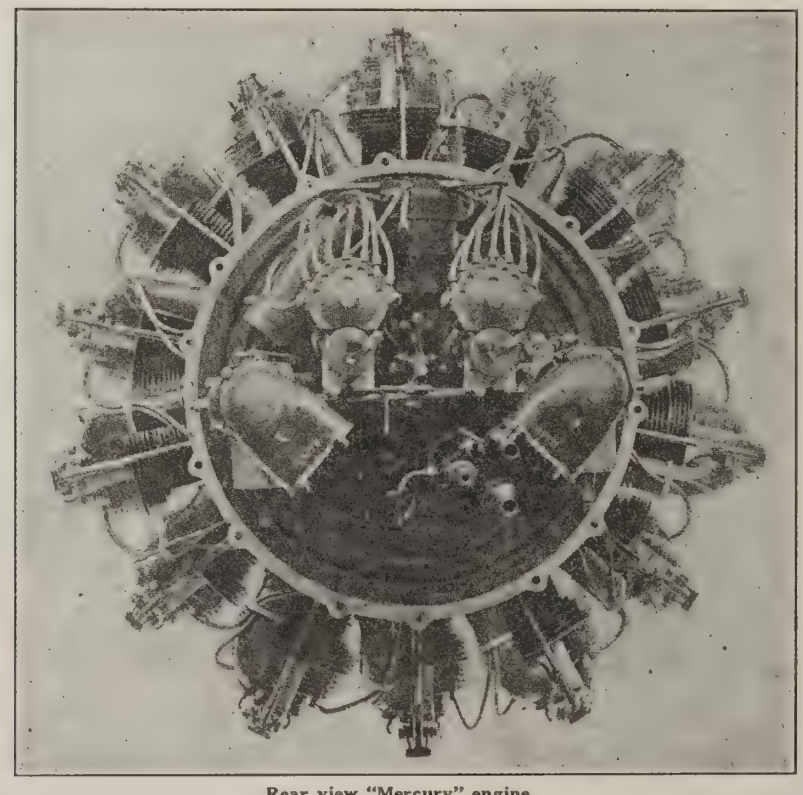
One of the firms who have specialized in the radial engine and have pinned their faith to the type is the Cosmos Engineering Co., Ltd., of Bristol, formerly known as Brazil, Straker & Co., Ltd., and still more formerly as Straker-Squire. To those who know their car histories little more need be said. The Cosmos Co. is not entirely identical with the car people, but it is not far removed as offspring go.

Research and experiment have led to the production of two radial engines by the firm—the "Mercury" of 315 h.p. and the "Jupiter" of 500 h.p., of fourteen and nine cylinders respectively. Other engines will be, and, indeed, are being, designed and produced, but upon the success of these two engines the makers have decided to commit themselves definitely to a program of peace-time production. Aero-engines are to be the product with which the Cosmos Engineering Co. will make their bid for prosperity, and radial engines are the particular type with which the firm will be concerned. Money and time and the inclination to make use of both are all at hand, and further experiment and research are to be continued.

Front view "Mercury" engine

The "Mercury" Engine

The "Mercury" engine—two rows of seven cylinders each—was introduced to satisfy Air Board Scheme A issued in April, 1917. Its main details are:—Maximum diameter, 41⅝ ins.; bore, 4⅜ ins.; stroke, 5 13/16 ins.; power output, 315 b.h.p. at 1,800 r.p.m. (normal) and 347 at 2,000 r.p.m. (maximum); total weight, without fuel and oil tanks, but with the engine absolutely complete even to the gun synchronizing gear, 582 lbs.



Front and rear view illustrations are reproduced herewith, which make quite clear the general lay-out of the unit, including the ignition apparatus of two 7-cylinder M.L. magnetos and Remy 14-cylinder distributor and the two carburetors bolted to circular induction chambers on the crankcase. The mixture is conducted from these chambers by separate induction pipes to each cylinder and admitted through one inlet valve. The three overhead valves per cylinder may be seen in the front view of the engine; the tappet gear is of the roller type, arranged in a circular unit, which can be assembled complete before attachment to the crankcase.

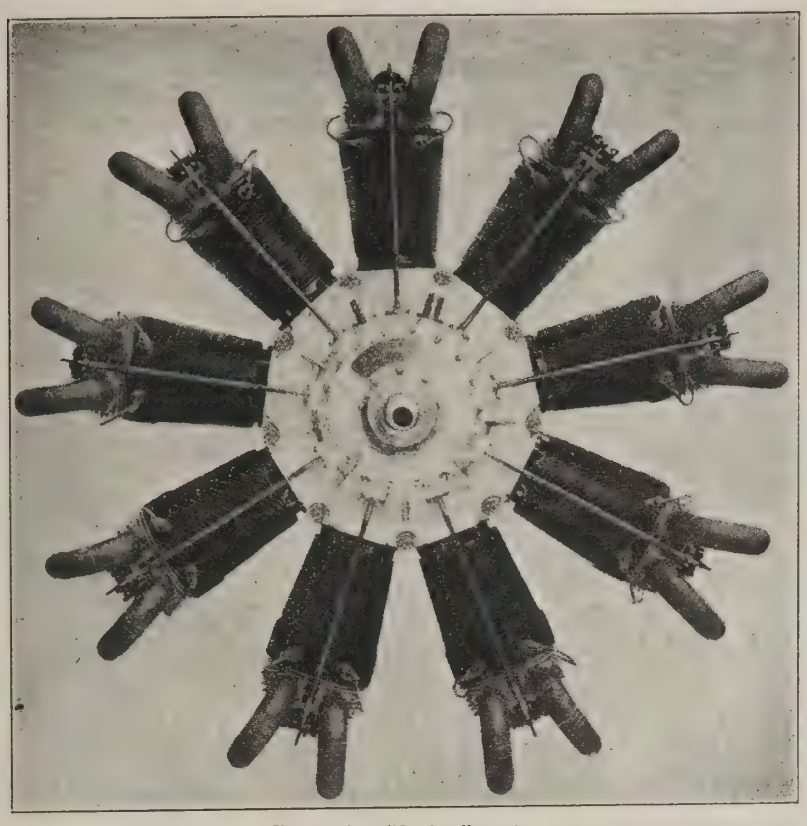
As regards constructional details not apparent in the illustration, the cylinders are turned from a solid billet, the fins integral with the barrel. Separate aluminium heads are bolted onto the cylinder barrels. These heads are so designed as to obtain effective cooling of the valve seatings and ports and to avoid all distortion. The crankshaft is of the two-throw type on roller bearings throughout. The rollers of the big-end bearings run direct on the crank-pin, and each connecting-rod has its own crankshaft bearing, so that the seven rods of each row of cylinders lie side by side on their respective crank-pins. An interesting feature of this part of the engine is that the whole crankshaft assembly can be withdrawn complete, with the connecting rods in position. The tappet gear is of the roller type, the tappets operated by two cam rings, each having three cams and working at one-sixth engine speed.

Lubricating is on the dry sump principle, and the oil is drawn by one pump from the tank mounted in the fuselage, delivered under pressure to the hollow crankshaft, and, after being led by separate leads to all necessary parts, is returned to the tank by another pump.

On this engine the airscrew is ungeared, the airscrew boss being driven direct through serration on the crankshaft. The airscrew boss is to Air Board standard design.

On the Bristol Scout Type "F" this engine has been given exhaustive flying tests, and has given extremely satisfying results.

Rear view "Mercury" engine



The "Jupiter" Engine

From one point of view the "Jupiter" engine may be classed with the Rolls "Condor" and the Siddeley "Tiger." The Armistice came at a time when it had done no more than prove its potentialities by means of bench tests, and, in the sphere for which it was designed—Hun strafing—the engine will never have its chance. With this in mind, one might be forgiven for regretting that the Armistice was not postponed till Christmas Day.

The rear view of the "Jupiter" engine makes clear many of its constructional features. There are nine cylinders made on lines similar to those of the "Mercury," but the bore and stroke are 5¾ ins. and 7½ ins. respectively, while the power output is 450 h.p. at 1,800 r.p.m. as an ungeared engine or 500 at 2,000 r.p.m. with a geared down airscrew. The weight of the ungeared model is 662 lbs. complete, including electric starter, but without fuel and oil tanks.

An Important Feature

From the illustration the engine might be taken to be of the rotary type, owing to the arrange-

Front view "Jupiter" engine

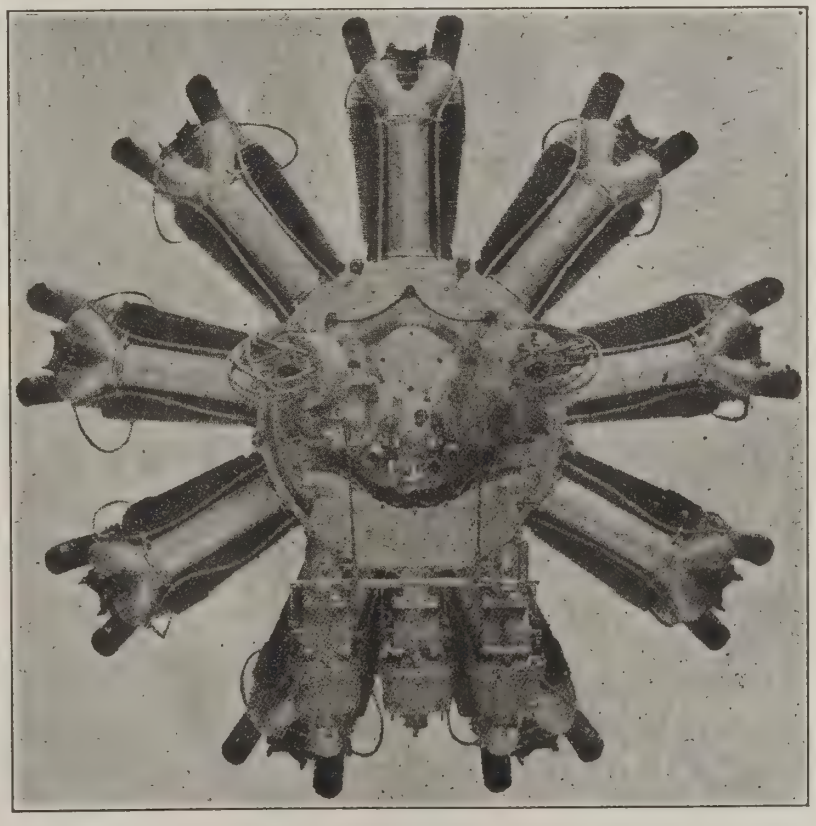
ment of the inlet pipes, which form part of a very interesting induction system. As will be seen, three carburetors are bolted to the crankcase cover, which also forms one side of the induction chamber.

This induction chamber is annular, and into it is fitted a spiral fluted aluminium casting which acts as a gas distributor to the cylinders. Each of the three carburetors supplies three cylinders *via* the spiral, which delivers the carbureted charge to the correct cylinder in turn, with the advantage that each cylinder is more efficently supplied with mixture, and, if one cuts out, none of the others is affected. On bench tests the arrangement has proved itself a success.

Two inlet and two exhaust valves are fitted per cylinder, operated by two cam rings, each with four cams running at one-eighth engine speed, through tappets mounted in the front of the engine. Ignition is by two 9-cylinder ??????°??-Bennet magnetos driven by bevel gearing from the crankshaft and mounted on the back cover of the crankcase—i.e., the cover of the induction chamber—in such a position that the contact breakers are readily accessible.

With the exception of the connecting-rod assembly, the engine is, in essentials, similar to the "Mercury." A master connecting-rod with articulated rods is used. The bearing of the master rod is white metal lined, all other bearings in the engine are of the roller type. It is hardly necessary to point out that the crankshaft in the "Jupiter" engine is of the single throw type.

It is difficult to say much by way of general review of engines that have not long been in the public eye and that have not had the opportunity of proving their mettle in continuous service. The induction system of the "Jupiter" engine and the cylinder head construction of both engines are, however, proof that the engines have brains behind them, and that precedent and tradition are not being followed blindly.



Locating Engine Troubles with the Geophone

The geophone, a listening instrument invented by the French during the war to detect enemy sapping and underground mining operations and for the location of enemy artillery, is capable of a number of interesting peace-time applications, according to the Bureau of Mines. These include the locating of miners who have been entombed after an accident, for bringing approaching tunnel headings together accurately, preventing accidents from explosion when breaking through and for locating underground fires and knocks in the valves and cylinders of automobile engines. When used for this last purpose the instrument, which is small and essentially a seismograph, should be mounted on a short iron rod that can be easily inserted in and around the machinery that is being tested.

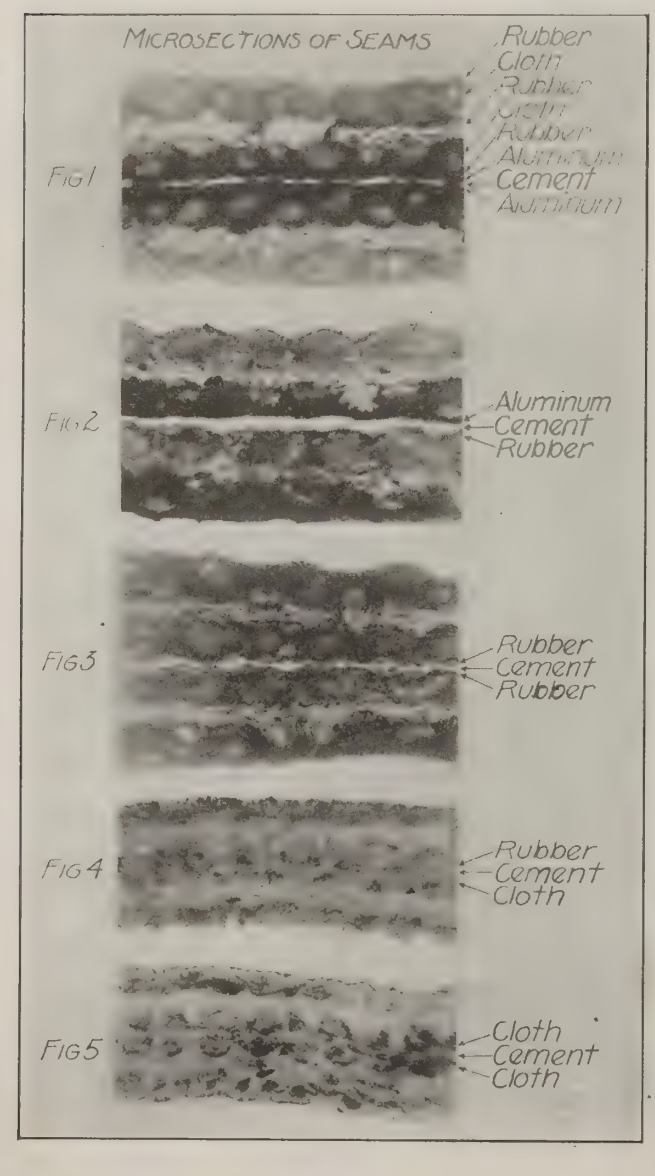
The instrument consists of an iron ring of about 3½-in. diameter with a lead disk suspended in its center. A single bolt passing through two mica disks, one of which covers the top and the other the bottom of the ring, serves to keep the lead disk in the proper position. Two brass cap pieces, the upper one having an opening in its center to which is fastened a rubber tube, leading to a stethoscopic ear piece, complete the instrument. Bolts fasten the cap pieces to the iron ring and also serve to hold the mica disks in place.

If the instrument which in reality is nothing but a lead weight suspended between two mica disks cutting across a small air-tight box, is placed on the ground, the energy due to any pounding or digging that may be going on in the vicinity is transmitted as a wave motion to the earth, and these earth waves shake the case. The lead weight because of its mass and also because it is suspended between the mica disks remains comparatively motionless. Thus the relative motion is produced between the instrument case and the lead weight, the result being that the air in the instrument is compressed and rarefied and this in turn is carried to the ear drum through the rubber tube connecting the instrument with the ear piece.

Two instruments, one for each ear, are ordinarily employed, and by moving them a point can be found where the sound will be of the same apparent intensity in both ears, thus enabling the direction from which the sound is coming to be determined accurately.

Rear view "Jupiter" engine

NOTES ON CEMENTED SEAMS AND RUBBER CEMENTS WITH REFERENCE TO BALLOON CONSTRUCTION



By J. D. Edwards, Associate Chemist and I. L. Moore, Assistant Chemist, Bureau of Standards

I. Introduction

RUBBER cement finds many uses in the industry, particularly for the fabrication and repair of rubber goods. Nowhere perhaps, is a knowledge of the principles underlying its use so essential as in the fabrication of a balloon, which requires the cementing together of the different pieces of fabric to build up the gores and panels which form the envelope, and for the attachment of appendages, and the cementing of patches. In addition to being gas-tight these seams must also bear considerable mechanical load, and although they may be further strengthened by stitching, it is of some importance that the cemented joint shall be as strong as possible because any slipping will throw an undue load on the stitching. Furthermore, any loosening or slipping of the seam will cause excessive leakage of the balloon gas.

The Bureau's attention was called to this matter by some experiments of the Goodrich and Goodyear rubber companies on cementing aluminum coated fabrics together. The unexpected result of these tests was that when the aluminum coating was buffed off, presumably to give a better holding surface for the cement, the cemented joint made thereon was inferior in strength to joints made without any preliminary treatment of the surface.

In endeavoring to arrive at the proper explanation for this fact we have made numerous tests on seams and cements. The object has been to establish the principles underlying good seam construction and to develop suitable methods for testing the seams and cements under investigation.

II. Characteristics of Seams

In constructing a balloon envelope there are a variety of surfaces that may have to be cemented together and, as we have already noted, the character of the surfaces has an important effect on the strength of the cemented seams. For determining the strength of seams which were to be investigated, the following test was adopted as a standard:

The seam was prepared by first washing with benzene or gasoline the surface to be cemented, and then applying smoothly two coats of cement. The first coat of cement was allowed to dry somewhat before applying the second coat. Before the second coat was fully dry, the surfaces were lapped and pressed firmly together by rolling with a steel roller; and the width of lap used was 0.5 inch. These seams were allowed to set for at least 24 hours before testing. Strips one inch wide were then cut from the larger pieces and suspended in a constant temperature air bath under a tension of 1 kilogram. The time required for the seam to break was taken as a measure of its strength.

(1). *Effect of Character of Surface.*—Seams were constructed of different kinds of balloon fabrics to show the effect of differences in the character of the surfaces on the holding power of the seam. The same sample of high-grade balloon cement was used in all of these seams. They may be described as follows: (1) Cloth cemented to cloth (CC), (2) rubber cemented to cloth (RC), (3) rubber cemented to rubber (RR), (4) rubber cemented to an aluminized surface (RA) and (5) aluminized surface cemented to an aluminized surface (AA). These seams were subjected to the test described above after permitting them to set for a suitable time. Table 1 gives the average of a number of determinations of the time required to break under a tension of 1 kilogram per inch of width at 55°C. Figures 6 and 7 which give the variation in the times required for the seams to break under different loads and at different temperatures, show graphically the relative strengths of some of these seams. They rank clearly in the following order, the strongest being placed first:

(1) Aluminized surface cemented to aluminized surface.
(2) Rubber surface cemented to aluminized surface.
(3) Rubber surface cemented to rubber surface.
(4) Cloth surface cemented to rubber surface.
(5) Cloth surface cemented to cloth surface.

This order and practically the same relative strengths were found to hold both when the seams were tested within 24 hours after they were made and also several weeks later. It is apparent from Figs. 6 and 7 that the relative strengths will vary somewhat with the conditions of test; this point will be disclosed in a succeeding section.

Table 1

RELATIVE STRENGTH OF SEAMS MADE BY CEMENTING DIFFERENT SURFACES TOGETHER

Seam No.	Description	Average time required to break at 55° C under a constant load of 1 kilogram per inch.
1	Cloth cemented to cloth...	7 minutes
2	Cloth cemented to rubber..	10 minutes
3	Rubber cemented to rubber	30 minutes
4	Rubber cemented to aluminized surface.....	100 minutes
5	Aluminized surface cemented to aluminized surface	400 minutes

2. *Essentials of good construction.*—The load on a cemented lap in an inflated balloon is almost entirely a shearing stress caused by the surface tension which results from the pressure of the gas in the envelope, and the weight on the suspension. This condition has been duplicated in the tests made by subjecting the test pieces to direct tension along their length, thus making the stress in the cement film a shearing one. Since there is no tensile force tending to pull the seams apart perpendicular to the fabric, the film having the greatest shearing strength is the most desirable.

For this reason as thin a coat of cement as is feasible to apply and insure complete adhesion to both surfaces is the strongest. Both the characteristics of the surface and the quality of the cement may defeat this purpose. If the cement is thick and lumpy great difficulty is experienced in getting a smooth coat and in securing complete wetting of the surface. If the surface is rough, the film is not maintained uniformly thin, even when spread smoothly. Rubber is comparatively inelastic and suffers shearing deformation easily. This deformation is particularly large in thick films and the load is consequently thrown onto the thin places, which give way under the unequal distribution of the load. The stress is then carried by the next thinnest place and so on until the lap slips apart. A smooth surface is also desirable because small irregularities may form cups which the cement bridges with a film and the consequent poor adhesion may result in the finished lap and a considerable portion of the cemented area not bearing its share of the load.

The actual physical properties of the surface are also of importance. Good adhesion is not secured if the surface is not wetted thoroughly by the cement. This purpose is defeated in the case of rough surfaces, as pointed out above. The presence of grease or dust on the surface also prevents the cement from adhering properly. For this reason, seams which receive a preliminary washing with benzene show somewhat higher strength than when the washing is omitted. Even in the case of very smooth, clean surfaces, however, adhesion may not be perfect because the cement may be separated from the surface by a thin film of air which will be detrimental to the strength of the seam.

A study of the microsections, Figs. *1*, *2*, *3*, *4* and *5*, demonstrates the validity of these assumptions regarding the factors contributing to strength. The aluminum to aluminum seam (Fig. 1), which is the strongest of any experimented with, shows a remarkably smooth thin film in which adherence to the aluminized surface is practically perfect, and which is free from thick places, bare spots and other imperfections. At the other end of the scale is the cloth to cloth seam, which presents a vastly different appearance. The cement film is very irregular and varies widely in thickness and closeness of adhesion from place to place. The other types of construction show characteristics ranging successively between these two extremes, none being so markedly poor as

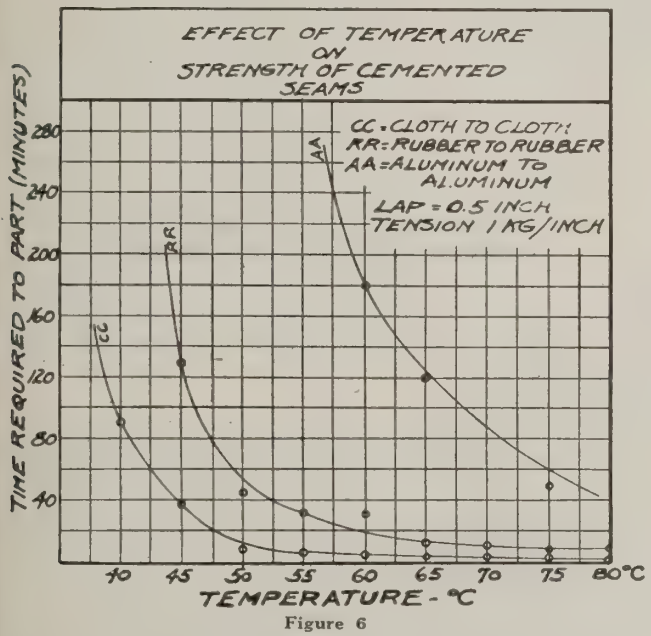


Figure 6

the cloth to cloth and none so good as the aluminum to aluminum seam.

To be sure of a strong seam, therefore, one must have a smooth, clean surface which will wet easily with the cement. The cement must be applied smoothly and evenly and the lap pressed firmly together before too dry.

(3) *Cements.*—In addition to the character of the surfaces cemented together, the kind of cement used also has a considerable effect on the strength of the seam produced. This is in the last analysis the determining factor, for as pointed out above, the seam fails in shear and the elastic properties of the cement determine the amount of shear even though the uniformity, adhesion and thickness of film modify the result. The best grades of balloon cement are

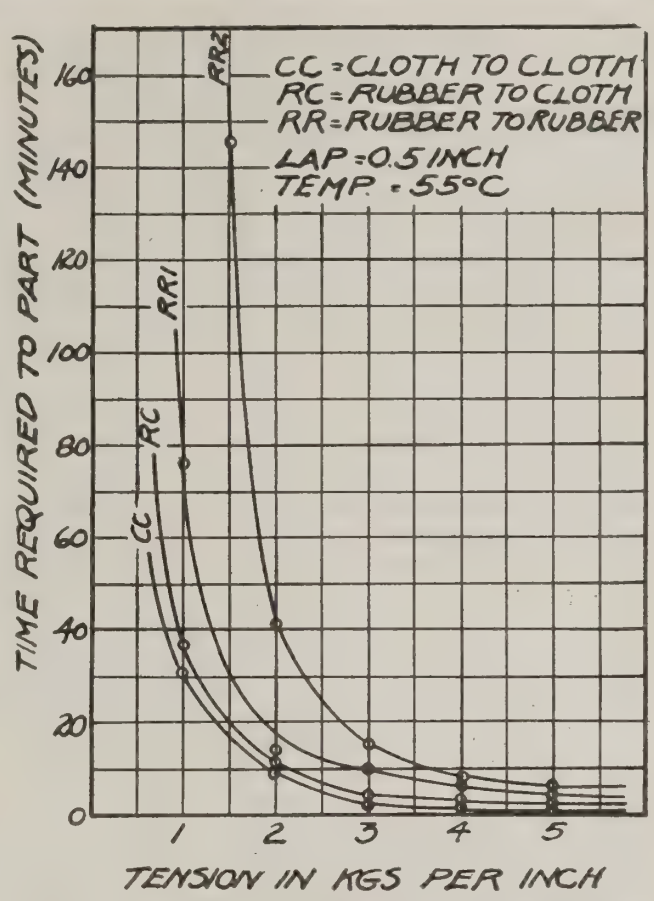

Figure 7—Relation of load to holding power of cemented seams

made by dissolving new rubber in benzene and thoroughly kneading the mass in a dough mixer. The finished cement must be smooth, free from lumps and thin enough to spread easily and smoothly on the surface to which it is to be applied.

Tests were made with two grades of commercial balloon cement, one grade of self vulcanizing tire cement, and one rubber cement made up by dissolving old raw rubber in benzene and mixing by hand. Seams were made with these cements by cementing two rubberized surfaces together; the results are comparable with the seam described in Table 1 as rubber to rubber (RR). The results of tests on these four cements are given in Table 2.

Table 2

RELATIVE HOLDING POWERS OF CEMENTS

Seam No.	Cement	Average time required to break at 55° C; lap = 0.5 inch; tension = 1 kg. inch
1	Old raw rubber dissolved in benzine; mixed by hand...	3 minutes
2	Balloon Cement; Manufacturer A.....	9 minutes
3	Balloon Cement; Manufacturer B.....	30 minutes
4	Self vulcanizing tire cement..	160 minutes

III. Testing Methods

The conditions of test have an important effect on the apparent strength of the seam, as would of course be expected. It is important therefore, that the conditions that effect the apparent strength shall duplicate, as far as possible, the conditions of service. For example, the tests were made under constant tension because the seams are under constant tension in a balloon. A load of 1 kilogram was used because it is at least of the same magnitude as the loads the seams may bear in service. Temperatures above ordinary air temperatures were used because of the increase in temperature of the balloon fabric when exposed to sunlight. In fact most seam failures occur when the fabric becomes "over-heated."

The effects of variations in the load, temperature of fabric

and width of lap were found by suitable tests in order that the conditions of test might be intelligently selected.

Effect of Temperature upon Strength of Seam.—As pointed out above, the failure of seams usually occurs when the laps have become overheated. In kite balloons with outside coatings of dyed or pigmented rubber, fabric temperatures of 25° to 35°C above air temperature are not uncommon during the summer. The temperature rise in the case of aluminized fabrics is somewhat less. To duplicate the conditions of service it was necessary therefore to make tests at a higher temperature than ordinary room temperatures, and 55°C was chosen as representing a fair point at which to make determinations of the relative strengths of the various types of laps. The effect of temperature on the time required to part was investigated in detail, however, to determine the variation in strength due to differences in temperature.

Seams were made up in the usual manner and placed in a constant temperature air bath under a tension of 1 kilogram per inch of width, and the time required for the seam to break at temperatures from 45°C to 80°C at 5 degree intervals was determined. Figure 6 shows graphically the relation between the temperature and time of break for three different types of seams. These all have the same general shape and all show a critical temperature region below which the strength of the seam is nearly a linear function of the temperature, the strength increasing rapidly as the temperature decreases. In this region there is presumably a transition from vicious to plastic flow; above this temperature the ordinarily plastic rubber becomes in effect a more or less viscous fluid depending on the temperature attained, and the lap parts very quickly. This transition point is not clearly marked, however, and is observed by variations in the strength of adherence of the cement to the different types of surface. In the case where the aluminized surfaces are cemented together, the time of breaking is more nearly a linear function than with the other types, which indicates very close adhesion to the aluminum surface, so that even when the viscous state is reached the time required to part is still quite high.

The extraordinary strength of cemented laps at ordinary temperatures is shown in Table 3. Pieces of three seams made up as described in the table were suspended under a tension of 25 pounds per inch of width at ordinary room temperature, which was between 25°C and 30°C. The best of these seams showed no tendency to slip during long periods of test. The method of test, while it shows the strength under ordinary conditions, does not duplicate the conditions of service and was abandoned for that reason.

Table 3

TEST OF SEAMS AT ROOM TEMPERATURE, ABOUT 25° C

Seam No.	Construction	Time required to part. Lap 0.5 inch; tension 25 lbs. per inch	
		1st Test Piece	2nd Test Piece
H	Rubber to aluminized surface; washed with benzine	Over 68 hours	Over 50 hours
I	Rubber to aluminized surface; untreated.....	13 hours	Over 50 hours
J	Cloth to cloth; rubber and aluminum surface buffed off with wire brush.....	48 minutes	71 min.

Note.—Seam I on first test piece showed a slight imperfection at the center of the lap where adhesion was not complete.

Tension.—In practice the load on a cemented lap may average about 1.5 kilogram (3.3 pounds) per linear inch. For testing purposes therefore, 1 kilogram per inch was chosen as a fair value. Tests were made, however, to determine the effect of different tensions on the apparent strength of seams. Figure 7 shows the variations of breaking time with loads of from 1 to 5 kilograms per inch at 55°C. A study of these curves shows that for loads above 2 kilograms per inch there is little difference in the time required to break for the various types of seams, so that, for testing purposes, loads below this value must be used to show the true variations in strength with different types of surfaces and cements.

Width of lap.—It is obvious that increased strength can be obtained by increasing the width of lap. This increase in strength is not a linear function, but increases roughly as the cube of the width of lap at small widths and even faster with wider laps. This is to be expected since the slipping apart is a gradual process dependent on the giving way one after another of the infinitesimal points of contact and when we have a wide lap we not only have more points of adhesion, but less stress is also put on each element of the cement film. This corresponds to a decrease in load and the slipping goes on much more slowly at the lighter loads, the decrease bearing much the same relation to the lap as that shown in our load curves (see figure 7). Figure 8 shows the relation between lap and

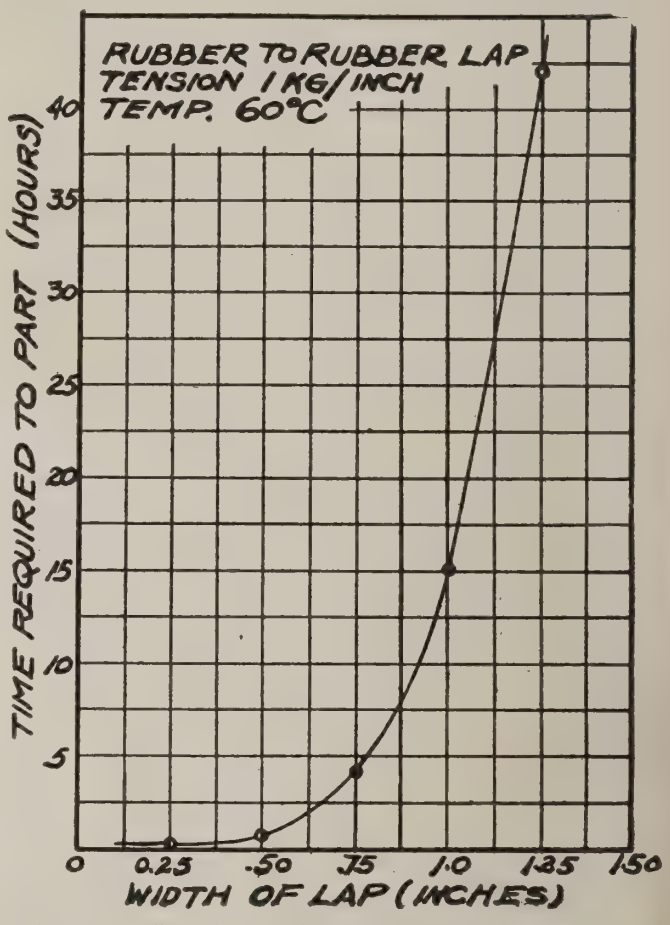

Figure 8—Effect of width of lap on strength of cemented seams

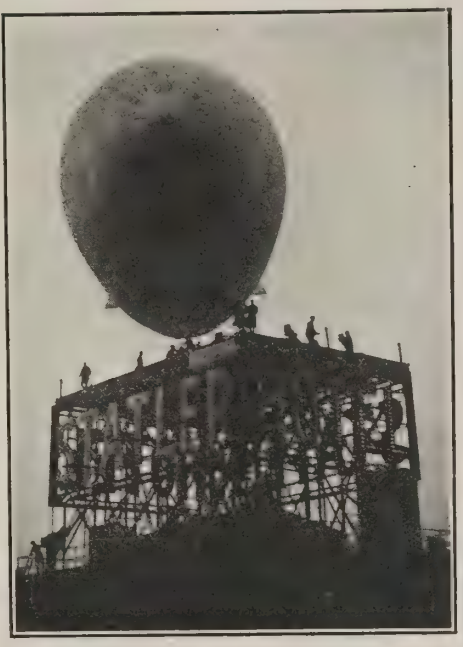
time required to part for five widths of lap. These tests were made at 55°C. with the seams under a tension of 1 kilogram per inch.

(4) *Coats of Cement.*—The evidence on the effect of varying the number of coats of cement is conflicting. This is to be expected since definite amounts of rubber cannot be spread when the material is merely brushed on by hand. It is essential, of course, to get sufficient rubber on the surface to give a continuous film all over it. Once this is done the addition of more of the material only serves to weaken the seam, since it allows more shearing deformation to take place when the load is applied. For most rubberized fabrics two coats are essential and sufficient. For aluminized fabrics one coat, if properly applied frequently gives quite as good a holding power as two coats and certainly better than three.



IV. Summary

We have shown by tests and the examination of microsections of cemented seams what the essentials of good seam construction are. A good seam requires, first of all, a good cement. Next the surfaces to be cemented should be smooth and cleam and easily wetted by the cement. The cement should be applied in a thin coat of uniform thickness; two coats are usually sufficient. The strength of the seam will be profoundly influenced by the character of the cemented surfaces. The variations in the strength with change in temperature, load and width of lap have been shown graphically. The methods of testing are described and the significance of different conditions of test is discussed.

DINERS TRAVEL VIA AIR ROUTE

A NEW era has been inaugurated in the aeronautic world in the wonderful performance of the first dirigible balloon built for the United States Army during the recent war—the A-4. This big airship, of the type familiarly known as "blimp," with Army Civilian Pilot James Shade at the wheel has just made the trip from the Wingfoot Lake Air Station, near Akron, Ohio, to Cleveland, landing on the roof of the Statler Hotel, discharging two passengers and immediately returning to its hangar 50 miles distant. This is the first time in the history of aeronautics in America that any type of aircraft has been brought to a quick and convenient stop in the heart of a large city for the purpose of landing passengers.

The occasion was the meeting and dinner of the Cleveland Section of the Society of Automotive Engineers at this hotel, at which Ralph H. Upson, chief aero engineer of the Goodyear Tire & Rubber Company, and Major C. H. Maranville, commander of the Army Aircraft Detachment at Akron and Wingfoot Lake, were speakers.

The successful landing on the roof of Hotel Statler

James F. Shade, who piloted the airship

Upson, who is the world's champion balloonist, having won the last great International Balloon Race at Paris, France, with R. A. D. Preston acting as aide, in a wonderful 500-mile flight, conceived the idea of making the trip in a dirigible, and with the full co-operation of the army officers of the dirigible school at Akron, who arranged all details, was able to carry out the project.

Glenn L. Martin, the noted inventor and pioneer manufacturer of aeroplanes, and one of the country's noted aviators, was the first to greet and congratulate the two passengers as they stepped from the car.

To the thousands of interested spectators of this history-making event the conclusion was inevitable that commercial dirigible navigation is almost upon us.

The performance was not staged as a "stunt," but to show the progress that has been made in the development of dirigibles and the skill with which difficult landings can be made by experienced pilots.

Army officers are delighted with the success of the undertaking. "We gladly entered into the spirit of the affair with the view of stimulating enlistments in the army airship training service at Wingfoot Lake," declared Major Maranville, who was officially in command of the A-4 on this memorable trip. "The demonstration proves beyond doubt that the airship is practical and that young men that enlist in this service have a wonderful future before them. We were glad to be able to point out that the dirigible has a commercial as well as a military value."

The piloting of James F. Shade on this occasion was pronounced by both army and civilian aeronautical engineers as the most skillful they had ever seen, and stamps him as one of the best dirigible pilots in America. The vast throng that witnessed his work in landing on the hotel roof, apparently realized the difficulties he was overcoming in this pioneer effort and broke into tumultous cheering as he guided the car of the dirigible to the center of the small improvised platform, erected on the electric sign for this purpose.

Ralph H. Upson, chief aero engineer, Goodyear Tire & Rubber Company

The Army dirigible A-4

The AIRCRAFT TRADE REVIEW

Propellers for NC Planes Were Two-day Rush Job

Baltimore, Md.—An example of the rapid work and efficient service of the American Propeller Company of Baltimore is afforded by the handling of the contract for the propellers for use on the NC squadron.

At the American Propeller Company's works one Saturday afternoon shortly before the start of the first stage of the flight, while the force was getting ready to quit and enjoy the holiday, when Washington rang in on long distance and a dozen propellers for the great flight were demanded in the shortest possible time. Lieutenant George S. Murray, of the Bureau of Steam Navigation, U. S. N., which had the matter in charge, was already on his way to Baltimore with drawings and specifications. The whole force of the Propeller Company was assembled and work began at 1 p. m., and through that night and Sunday was continued without break. At 7 p. m. Sunday the 12 propellers were made and varnished. A day was required for the varnish to dry, and on Monday night in a special baggage car, with Lieutenant Murray beside them, the propellers started for Boston; on arrival there early Monday morning by special trucks they were taken to the fast torpedoboat destroyer Edwards, waiting with steam up; the hatches were found too small to take the propellers below, and they were lashed on deck and the boat, under forced draft, started for Trepassey bay.

These Baltimore-made propellers were delivered at this far-off Newfoundland point on the afternoon of Wednesday, May 14, four days from the time of their being ordered.

The propellers were of the ordinary two-blade type, 10 feet in diameter, and were for the three tractor engines of each plane to pull a gross load of 28,000 pounds at an expected speed of 85 miles an hour.

The company received the emcomium of naval officials for the efficient handling of the contract.

Albuquerque School Moves to Wichita

Wichita, Kans.—The company which organized the aviation school at Albuquerque, N. M., has organized a $25,000 corporation at Wichita. Their equipment is being moved to this city because the high altitude at Albuquerque made it unsafe for instruction purposes.

The Board of Commerce of Wichita is co-operating with the company in the establishment of a first-class landing field under government specifications. Regular passenger trips between Wichita, Kansas City and Tulsa, or any point within 250 miles' radius will be established where the demand warrants. The school's equipment consists of five aeroplanes and instruction in flying, wireless, astronomy and meteorology will be given by the faculty.

Air Travel Firm Formed

An aeroplane transportation company has been organized to link up Detroit and Cleveland by direct air route over the Detroit River and Lake Erie. Daily trips, weather permitting, will be made each way, the planes leaving at 9 o'clock in the morning.

The commercial enterprise has been undertaken by the Universal Aviation Company, and is backed by many prominent Detroit and Cleveland automobile manufacturers. H. M. Leland, of Detroit, who was former president of the Cadillac Motor Car Company and now president of the Lincoln Motor Company, and E. E. Allyne, president of the Aluminum Casting Corporation of Cleveland, are heading the project as president and first vice-president, respectively. H. D. McCullough is secretary and treasurer of the company.

John T. Patterson, the general manager of the company, has come here to engage additional pilots and to arrange for the shipping of five aeroplanes. He announced that the first flight would be made, if possible, on June 10. Passengers, he said, will be charged $50 for a one-way trip. Express packages will be carried for 32 cents per pound, and mail 2 cents an ounce. He points out that although Cleveland and Detroit are but 80 miles distant the fast express trains take eight hours to make the trip, for the reason that a detour by way of Toledo around the southern end of Lake Erie is necessary.

Two aviation fields with hangars and buildings have been established in Detroit. One is opposite Belle Isle, just east of the bridge, and another at Morrow Field. It is planned to operate training schools for aviators on these aerodomes as well as another at the flying field in Cleveland.

Dixie Flying School Organized

Birmingham, Ala.—The first Civilian Flying School to be organized on a large scale in the South since cessation of hostilities has been completed here with the issuance of a charter to the Dixie Flying Corporation. Under the terms of the charter the company will conduct a large school for civilians and will include in the course a complete ground school of instruction. Standard Army Training planes will be used in the training. The company will in addition handle an extensive line of aeroplanes, including a full stock of parts, and will keep open at Birmingham at all times a service field for any planes that might come that way.

The company is the largest, both from a point of financial backing and actual holdings of fields, planes and all equipment for training yet organized in the United States, it is believed. Scores of men have already been employed in completing the preliminaries and by the opening some thirty days from now the Dixie Flying Corporation will employ more than 100 persons, including instructors, mechanics, clerical, field officers and other personnel such as salesmen, stock foremen.

Chicago-Cleveland Air Route Shows High Efficiency and Reliability

The Chicago-Cleveland Air Mail Service during its first half month has made a daily 100 per cent. performance except two half trips, May 21, when the field at Bryan, Ohio, was so flooded that the planes could not rise from the ground.

Out of a possible mileage of 11,050, a total of 10,725 was run, making a performance of 97.1 per cent. A grand total of 408,560 letters were carried in the first half month of this service. In the operation of the Cleveland-Chicago Air Mail the greatest forward step in cross country work has been taken in that since May 21 the daily trips in each direction are about 325 miles non-stop. Twenty such non-stop trips were made without motor trouble of any kind, and with a single mishap in the nature of a fire in the pilot's cockpit of a plane operated by Pilot Frank McCusker, resulting in the death of that pilot. This has been the only fatality to any pilot carrying the mail since the service was established, May 15, 1918.

The remarkable long distance, non-stop flights on the Chicago-Cleveland route are being performed by the De Haviland planes strengthened for cross-country mail carrying and equipped with low compression Liberty motors. The best time made on any trip between Chicago and Cleveland was 2 hours and 42 minutes for 325 miles, and the longest trip was 4 hours, due to a bad headwind. The average speed for the half month was 98½ miles per hour, and the average gas consumption was 23⅕ gallons per hour. The mail leaves Cleveland and Chicago at 9:30 o'clock each morning, including Sundays, and arrives at its destination usually between 12 and 1 o'clock in the afternoon.

Aerial Mail Service for the Philippine Islands

Among the plans for aerial mail services with which forward-looking people are busy in various parts of the world, one which has promise of realization within a reasonable time because of the comparative simplicity of the practical problems to be solved is that of an aeroplane mail connecting important points in the Philippine Islands—as Manila to Cebu and Manila to Iloilo. The distance in each case is well within the limits of a non-stop aeroplane flight, and is yet sufficiently great to make the saving of time over that of the steamship mail routes a controlling factor in the choice. While nothing very definite seems to have been done as yet toward putting such mail routes into existence, the Director of Posts for the islands, José Topacio, is considering various recommendations from aeroplane and flying experts, and recommendations on the subject to the Philippine Legislature may follow.

Concrete proposals for a mail service to various points within flying radius of Manila have also, according to the Manila press, been presented to the authorities by H. J. Folsom, lately an officer in the United States Army Air Service, and an instructor at various flying fields during the war. A Manila paper quotes Folsom as follows:

"It is in the lightly populated regions and in island commerce that we all look forward to the most rapid development in commercial flying. There are in China and in other parts of the Orient many important commercial centers which cannot be linked with neighboring centers by rail owing to the mountains, jungle or water. In such inland regions rail lines depend largely on the business continuously along the line for their support, and a long barren stretch can often render a rail line inadvisable, even though the terminals might offer large inducements. Railroading under such physical conditions is very expensive, but an air service does not depend on interterminal business. Therefore airmen generally believe that air routes are the solution of many problems similar to that of island communication in the Philippines."

Salvage Motors and Aeroplanes to be Sold to Public

Those contemplating the purchase of a Government aeroplane or motor, can write the Salvage and Sales Branch, Air Service, 6th and "B" Streets, Washington, D. C., and have their name entered on the list to be advised when the opportunity arrives for them to make a purchase. Detailed information furnished on request.

One of the Curtiss J.N.4-H Mail Aeroplanes with a 150 H.P. Hispano-Suiza engine. The mail compartment is situated at the center of gravity. The markings on the side of the fuselage indicate that it has a maximum carrying weight of 3,500 pounds

NAVAL and MILITARY AERONAUTICS

Commander Towers Ordered to Duty With Commission for Air Terms

Washington, June 6.—Commander John H. Towers, Flight Commander of the Navy Transatlantic Seaplane Squadron, was relieved of all duty with that squadron on June 6 and assigned to service with the Commission for Air Terms now sitting at Paris.

One Hundred Nieuports to Be Shipped to United States

Washington, D. C.—According to an official statement, it is estimated that 100 Nieuport-28 aeroplanes will be available for shipment to the United States as the result of settlements with the French.

New Naval Dirigible C-8 Flies 450 Miles in 8 Hours

Cape May, N. J., June 3.—The U. S. Navy Dirigible C-8 arrived here after a 450-mile flight from Akron, Ohio, which was accomplished in a flying time of eight hours. She passed over Washington at 12:50 p.m., having left Akron at 6 a.m., and arrived at Cape May at 6:15 p.m. Over the mountain region she made 47 miles an hour.

The C-8 has just been completed. It is the largest non-rigid dirigible yet built by the navy. It was in command of Lieutenant Commander Paunack. With him were Lieutenant Laurence and Lieutenant Larned, U. S. N. R. F., and Gunner Anthony and Machinist Mates Keller and Crampton.

Major Cushman Hartwell Returns to Washington to Become Executive Officer of Information Group

After six months spent in Siberia, Major Cushman Hartwell has returned to Washington and taken up the duties of executive officer in the office of the Information Group. Before going overseas Major Hartwell was executive officer of the Training Section.

Capt. Craven Recommends Retention of All Naval Air Stations to House Naval Committee

Washington, D. C.—Retention of all naval air stations now in operation was recommended to the House naval committee on June 5 by Capt. Craven, director of naval aviation. He declared the stations were necessary to maintain the present efficiency of the service.

Capt. Craven also recommended an appropriation of $6,500,000 for three dirigibles, one of which would be purchased from Great Britain at a cost of $2,500,000. Other appropriations requested included $3,933,000 for the marine corps air service, stations for which would be maintained at Quantico, Va., and Paris Island, S. C.

New Reserve Military Aviators

The following named officers, having completed the required tests, are rated as Reserve Military Aviators: Second Lieutenants John Blaney, Floyd P. Roberts, Charles S. Wages, First Lieutenant Harry A. Dinger, Captain Elmer E. Adler, A. S.

Col. Fuller Presents $30,000,000 Estimate for Plane Construction to House Committee

Washington, D. C.—In speaking before the House Committee on Military Affairs on June 4th Colonel Fuller submitted estimates of $29,722,500 for the construction of aeroplanes and equipment. Of this amount he said there was an item of 650 planes at a total of $17,625,000, one of Hispano-Suiza motors at $7,325,000, and one for the purchase of pursuit planes for Hawaii, the Philippines and the Canal Zone at $4,312,500. The purchase and construction program also called for an appropriation of $3,074,000 for airships, including one semi-rigid, nine non-rigid and one rigid dirigible. The rigid ship, he said, would be purchased from the British government, it being an exact duplication of the latest British dirigible, 692 feet in length and with a capacity of 2,000,000 cubic feet. This data was furnished by General Mitchell, who strongly advocated the inclusion of this item in the budget, explaining that the British had found themselves seriously handicapped during the war through a need for this type of ship. An item of interest to the committee was one for $100,000 for the training of Reserve officers in summer camps, this being the first appropriation asked for the purpose of paying and transporting Reserve officers.

Navy Has 1,000 Flying Boats and 700 Training Planes

Washington, D. C.—According to statements made by Captain Craven of the House Military Affairs Committee, the flying equipment of the Navy Department consists of 1,051 large flying boats and 763 school 'planes.

War Department Renews Lease on Wilbur Wright Field

Washington, D. C.—The War Department has renewed the lease on Wilbur Wright Field for use as a permanent storage and training depot. The tract comprises 1,100 acres.

No Civilian Training Camps This Year

Washington, D. C.—An official statement issued by the War Department announces that owing to lack of funds and uncertain conditions training camps for civilians are not contemplated this year.

Air Service Officers Discharged

Washington, D. C.—The following officers of the Air Service have recently received their discharge: Captain Herbert E. Ives, Second Lieut. Herman G. Oliver, Maj. Edward P. Curtiss, Second Lieut. Gilbert D. Deere, First Lieut. William H. Harris, Jr., Capt. Robert C. Disque, First Lieut. Edward Schoeppe, Second Lieut. DeWitt F. Ottman, First Lieut. Robert Steinberger, Second Lieut. Charles H. Dauphin.

Reserve Officers to Receive Credit for Active Service

Washington, D. C.—The War Department authorizes publication of the following information:

The Secretary of War is submitting to the chairmen of the Committees on Military Affairs, of the Senate and House of Representatives a draft of a proposed joint resolution to make it possible that members of Reserve Officers Training Corps shall receive credit for active service in the army or for special training received during the period of the emergency. It is proposed that the amount of such credits be determined by regulation to be prescribed by the Secretary of War.

Demobilization of Air Service

According to reports received from the Air Service, the net decrease in the total commissioned and enlisted strength from the date of the armistice to May 22 was 78 per cent.

The following table shows the present distribution of personnel, as compared with the figures for November 11, and per cent of net decrease. The May 22 figures do not include 332 officers and 3,047 enlisted men on detached service or at camps awaiting discharge.

	Nov. 11	May 22	Per cent net decrease
Cadets	6,483	259	96
Enlisted men	170,436	37,329	78
Officers	20,852	5,076	76
Total	197,771	42,664	78

During the week ended May 22, 1919, the decrease in the Air Service personnel overseas was 1,186, as against a weekly average of 3,570 for the three preceding weeks.

The strength of the Air Service in the U. S. and overseas on November 11 and May 22 was:

	United States	Overseas
Nov. 11	119,882	77,889
May 22	15,580	27,084

Reserve Military Aviators Appointed

Washington, D. C.—The following named officers, having completed the required tests, are rated as Reserve Military Aviators: Capt. Horace Green, First Lieut. Armin F. Herold, Second Lieut. Bruce Cleveland, Second Lieut. Harold S. Purdy, Second Lieut. Ernest Goodrich, Second Lieut. Wayne V. Pittman.

Recent Naval Orders

Lieut. Com. Robert A. Lavender, to post graduate instruction in radio engineering.

Lieut. (junior grade) William Vanderbilt, Jr., to duty Naval Air Station, Rockaway Beach, L. I., N. Y.

Lieut. (junior grade) Braxton Rhodes, to duty Naval Aviation Detachment, Langley Field, Va.

Lieut. Willis B. Haviland, to duty Naval Aviation Detachment, Langley Field, Va.

Lieut. (junior grade) Braxton Rhodes, to duty Naval Air Station, Rockaway Beach, L. I.

Lieut. Com. Newton H. White, Jr., to command Naval Air Station N. O. Base, Hampton Roads, Va.

Lieut. Leman L. Babbitt, to command Naval Air Station, Montauk, L. I., N. Y.

Capt. Stanley V. Parker, to Naval Air Station, Pensacola.

Lieut. Edwin S. Parsons, to duty Naval Air Station, Rockaway Beach, N. Y.

New Insignia for American Aircraft

Washington, May 24.—The distinguishing insignia on American aircraft has been changed by order of the War and Navy Departments and will hereafter be a red circle inside of a white five-pointed star inside of a blue circumscribed circle. The circumference of the inner circle will be tangent to the lines forming a pentagon made by connecting the inner points of the star. The inner circle will be red, that part of the star not covered by the inner circle, white, and that part of the circumscribed circle not covered by either the inner circle or star will be blue.

The insignia is to be placed on the upper and lower surface of the upper and lower planes of each wing so the circumference of the circumscribed circle will be tangent to the outer tips of the planes. One point of each star must be pointed directly forward and the diameter of the insignia which can be either painted on or applied by decalcomania transfer, must be 60 inches.

The rudder insignia will be three equally wide bands, red, white and blue. Both sides of the rudder, in the rear of the rudder post, will be striped parallel to the vertical axis of the plane, with the blue stripe nearest the rudder post, the white in the center and the red at the tail of the rudder.

Special Orders Nos. 123-129 Inclusive

So much of par. 213, S. O., No. 46-O, Feb. 25, 1919, War Department, as rates the following-named officers as military aviators, from the dates indicated in that order, is amended so as to rate such officers as military aviators to date from Feb. 24, 1919: Lieut. Col. William Thaw, Maj. David M. K. Peterson, Capt. Douglas Campbell, Capt. James A. Keating, Capt. Reed G. Landis, Capt. Edward V. Rickenbacker, First Lieut. William P. Irwin, First Lieut. E. W. Springer, Second Lieut. John O. Donaldson.

So much of par. 37, S. O., No. 48-O, Feb. 27, 1919, W. D., as rates the following-named officers as junior military aviators from the dates indicated after their names is amended so as to rate such officers as junior military aviators to date from Feb. 24, 1919: Capt. James A. Keating, Capt. Edward V. Rickenbacker, Capt. Edgar G. Tobin, First Lieut. Frank Baer, First Lieut. Louis G. Bernheimer, First Lieut. Charles W. Drew, First Lieut. William P. Erwin, First Lieut. Robert F. Raymond, First Lieut. E. W. Springs, First Lieut. George A. Vaughn, First Lieut. Donald D. Warner, Second Lieut. Earl W. Porter.

The following-named second lieutenants will proceed to Camp Pike, Ark.: John D. Goodrich, John H. Madden, Earl D. Sylvia.

Second Lieut. David F. Davis will proceed to San Antonio, Tex., reporting to the Aviation general supply depot.

Capt. Hugh M. Pierce will proceed to Washington, D. C., and report to the Director of Air Service.

Second Lieut. Max V. Doten will proceed to Aberdeen Proving Grounds, Aberdeen, Md., and report to the commanding officer of the 271st Aero Squadron.

Capt. Clarence B. Hammond, Air Service, will proceed to New York City on official business in connection with the employment of discharged soldiers, and upon completion of the duty enjoined will return to his proper station at Washington, D. C.

The following-named officers are relieved from duty in the office of the Director of Air Service, and are assigned to duty at Bolling Field, Anacostia, D. C.: Second Lieuts. Nathan P. Oakes, Mark A. Hamilton, Clayton C. Shangraw, Patrick M. Logan, Estell H. Rorick, Philip D. Lucas, Otis L. Gilmore, Charles R. Dauphin, Ernest E. Harmon, Lyman Patterson, James E. Adams, Edward J. Sullivan, Jr., Grisson E. Haynes, Herbert E. Metcalf, Roland L. Spencer, Raymond P. Birdsall, Edward H. Hill.

The following-named officers are relieved from duty in the office of the Director of Air Service, and are assigned to duty at Bolling Field, Anacostia, D. C.: Lieut. Col. Rutherford S. Hartz, Maj. William M. Conant, Capt. Eugene C. Braig, Capt. Roy R. Showalter, Capt. Felix Steinle, Capt. George B. Hoagland, Capt. Henry E. Reece, Capt. Benni Goldblatt, Capt. Carl Crosse,

First Lieut. Shoptaw, pilot and "Jimmy" Shade, assistant pilot of the Army dirigible A-4, which landed on the roof of Hotel Statler recently

First Lieut. Ray A. Dunn, First Lieut. Edward B. Preis, First Lieut. Lotha A. Smith, First Lieut. Marshall S. Boggs, First Lieut. Robert H. Ellis, First Lieut. Leo F. Post, First Lieut. Charles W. Lamborn.

Second Lieut. Landreth M. Harrison, now on sick leave, will proceed to Fort Snelling, Minn., and report to General Hospital No. 29.

Second Lieut. Herbert S. Sawyer, now a patient at General Hospital No. 2, Fort McHenry, Md., will proceed to Hazelhurst Field, Long Island, N. Y.

Second Lieut. Herbert R. Kendall, now at General Hospital No. 2 Fort McHenry, Md., is transferred to Letterman General Hospital, San Francisco, Cal.

First Lieut. Edmund A. Clune will proceed by rail, on or about June 3, 1919, from Washington, D. C., to New York, N. Y., thence by aeroplane to San Francisco, Cal., on temporary duty in connection with the Air Service of the Army, for the purpose of taking part in transcontinental flight, and will return by aeroplane, upon completion of this duty, to his proper station, Washington, D. C.

First Lieut. Richard D. Collins will proceed from Rockwell Field, San Diego, Cal., to Washington, D. C., and report to the Director of Air Service.

The appointment on May 28, 1919, of First Lieut. Albert Joshua Clayton, for the period of the existing emergency, to the grade of captain, Air Service, is announced.

First Lieut. William F. Carroll is relieved from further duty in the office of the Director of Air Service, and will report in person to the Chief of Staff for duty with the geographic branch of the Military Intelligence Division.

Lieut. Col. Millard F. Harmon, Jr., now in Washington, D. C., at the expiration of the duty assigned him under par. 2, S. O., No. 65, Panama Canal Dept., May 10, 1919, will report to the Director of Air Service for temporary duty not exceeding 15 days.

Capt. Paul P. Magoffin will report to the Chief of Staff for duty with the Historical Branch, War Plans Division.

First Lieut. Charley Miller will proceed to Camp Dodge, Iowa, and report not later than June 3, 1919, to the commanding general for duty in connection with the rifle matches, 1919, and upon the completion of this duty will return to his proper station.

Second Lieut. John L. Leonard, Aviation Service, now a patient at General Hospital No. 32, Chicago, Ill., is transferred to General Hospital No. 40, St. Louis, Mo.

Second Lieut. William G. Davidson will proceed to Camp Travis, Tex.

Second Lieut. Samuel F. Hurt will proceed to Hazelhurst Field, Mineola, Long Island, N. Y., thence to Fort Hancock, N. J., thence to Little Silver, N. J., on temporary duty; thence to Hazelhurst Field, Mineola, Long Island, N. Y.

Par. 70, S. O., No. 105-O, W. D., May 5, 1919, directing First Lieut. William J. Doyle to proceed from Buffalo, N. Y., to Washington, D. C., is amended so as to direct him to proceed from Buffalo, N. Y., to Taylor Field, Montgomery, Ala.

By direction of the President, the following-named officers of the Signal Corps are relieved from detail in that corps, to take effect June 2, 1919, and are detailed for service and to fill vacancies in the Aviation Section, to take effect June 3, 1919: Maj. Joseph B. Douglas, Capt. James G. Boswell, Capt. Oscar Westover, Capt. John W. Simons, Jr., Capt. Roy M. Jones, Capt. Ora M. Baldinger, First Lieut. Edwin J. House.

Second Lieut. Peter W. Welch will proceed to Cleveland, Ohio; thence to Dayton, Ohio; thence to Cleveland, Ohio; thence to Hazelhurst Field, Mineola, Long Island, N. Y., for the purpose of testing navigation instruments to be used on transcontinental flight, and upon completion of this duty will return to his proper station, Washington, D. C.

The following promotions for the period of the existing emergency are announced: To be captain, First Lieut. John D. Hartigan. To be first lieutenants, Second Lieuts. Harold Kenneth Atkinson, George W. Rowden, Clarence Herkel Johnson, Frederick Hamilton Lovenberg, Franklin J. Rosemeir, Malcolm E. Schroyer.

First Lieut. Elmo N. Pickerill will proceed to Fort Sill, Okla.

Second Lieut. Robert K. Hall, upon the expiration of his present sick leave, will proceed to Walter Reed General Hospital, Takoma Park, D. C. for treatment.

Second Lieut. Charles R. Colt will proceed to Bolling Field, Anacostia, D. C.

Capt. John A. Macready will proceed to Dayton, Ohio, and report to the Chief Engineering Division, Air Service, for duty.

Maj. Maurice Connolly is relieved from further duty in the office of the Director of Air Service, and will report to Hazelhurst Field, Mineola, Long Island, N. Y.

Second Lieut. George H. Burgess will proceed to Fort Hancock, N. J., on temporary duty, thence to Hazelhurst Field, Mineola, Long Island, N. Y.

Second Lieut. Winfield S. Hamlin will proceed to Hampton, Va., for assignment to the School of Aerial Photography.

So much of par. 213, S. O., No. 46-O, Feb. 25, 1919, W. D., as rates First Lieuts. Merton L. Campbell and Lloyd A. Hamilton as military aviators is revoked.

Capt. Chilion F. Wheeler will proceed to Washington, D. C., on temporary duty not to exceed 10 days, thence to Hazelhurst Field, Mineola, Long Island, N. Y.; thence to San Diego, Cal., on temporary duty; thence to San Francisco, Cal., reporting upon arrival to the general superintendent Army Transport Service, Fort Mason, San Francisco, Cal., for transportation to the Philippine Islands, and upon arrival there report to the commanding general Philippine Department for duty.

Maj. James M. White will proceed to San Francisco, Cal., and report to the General Superintendent Army Transport Service for transportation to the Philippine Islands, and upon arrival at Manila will report to the commanding general Philippine Department.

Second Lieut. Ben B. Ehrlichman will proceed to Sacramento, Cal., and report to the commanding officer Mather Field.

Second Lieut. Rudolph L. Ehrlichman will proceed to Sacramento, Cal., and report to the commanding officer Mather Field.

Second Lieut. Wallace Brown is relieved from further treatment at Hospital No. 2, Fort McHenry, Md., and will proceed to Hazelhurst Field, Long Island, N. Y.

First Lieut. Eugene R. Scroggie is relieved from further treatment at General Hospital No. 2, Fort McHenry, Md., and will proceed to Hazelhurst Field, Long Island, N. Y.

(*Continued on page 702*)

FOREIGN NEWS

Santiago-Valparaiso Aerial Mail Service in Regular Operation

The first regular aeroplane mail service to be maintained in South America is that which operates between Santiago and Valparaiso— the two main centres of population in the Republic of Chile. The Chilian railway system is unsatisfactory, the journey between the two cities occupying some three hours, excluding the wait for half an hour or so which is the invariable rule at the half-way junction of Llay-Llay. For the new mail-carrying service, which has been in successful operation for some weeks, a number of the Bristol monoplanes which were recently presented by the British to the Chilian Government, are employed. The Chilian pilots employed have proved particularly skilled in their work.

No Sales of German Aircraft Permitted

Paris.—General Nudant, on behalf of the Allied Governments, has informed the German Armistice Commission that all sales of German aeroplanes to foreigners are forbidden, and has demanded the immediate steps be taken to put a stop to such sales.

Peace Treaty Delivered by Aeroplane

In order that the Peace Treaty could be in the hands of the German Government at the same time as the terms were formally presented to the German delegates, a Versailles on May 7, a copy was dispatched by aeroplane on the previous day to a Rhine aerodrome, when another machine conveyed it to Weimar.

On a French military machine, the Danish Lieutenant Pauli Krause, accompanied by Lieutenant Sabouret, on May 10 flew from Villacoublay to Copenhagen in 8 hours, carrying a copy of the Peace Treaty to the Scandinavian Governments.

Aerial Transportation in Vancouver

A message from Vancouver, B.C., states that the first aerial transportation company began business there a few weeks ago. A landing ground of 26 acres has been secured, and hangars are being erected. Flights can be made for pleasure or commercial purposes. Three two-seater machines are available, with former members of the R.A.F. as pilots and mechanics.

Conditions of Australian $50,000 Prize

It is stated that the preliminary conditions of the Australian Government's offer of a $50,000 prize for the first Australian airman to fly from Great Britain to the Commonwealth have been arranged at a conference attended by representatives of Mr. Andrew Fisher (High Commissioner for Australia in London), the Royal Aero Club, and the Air Ministry.

The prize, which must be won before December 31, 1920, is open only to Australians in seaplanes, flying boats, or aeroplanes of all-British make. The distance, varying from 15,000 to 17,000 miles, according to the route, must be completed in 720 hours.

Canadian Air Force to Be Disbanded

Ottawa, June 2.—The Canadian Air Force—organized a year ago and made up of two fighting squadrons—soon will be only a war memory. Official announcement of its disbandment is expected to be made by the Government in the near future.

A strong fight has been made to retain some portion of the organization intact, famous Canadian aces like Captain Bishop, V. C., and Captain Barker, V. C., interesting themselves in the proposal; but as the scheme involved an intial expenditre of $10,000,000 the Government, for financial reasons, has decided against it.

The Canadian Air Force was organized upon the insistent demand of the Canadian people that the Dominion should be represented at the front by a distinctively Canadian flying corps. Up to that time, although at least 40 per cent. of the British flying corps was made up of Canadians, Canada had no force of her own.

Madrid to London Flight Made in 12 Hours by DH-4

London.—A British aeroplane flew from Madrid to London recently within 12 hours. The train journey takes about 45 hours.

There were two stops for food and petrol. The route followed represents a distance of 987 miles, or more than half the distance across the Atlantic between Newfoundland and Ireland. The speed works out at about 78 miles an hour.

This magnificent feat was accomplished by Lieutenant-Colonel W. D. Beatty, R.A.F., with Lieutenant G. M. Jeffery, R.A.F., as observer, in a DH-4 military machine with a single 350-h.p. Rolls-Royce Eagle Mark VIII engine.

Colonel Beatty left Madrid at 6.15 a.m. He landed at Kenley aerodrome, near Croydon, at 6 p.m.

The first stop was at Pau, after a high flight across the Pyranees, and the second at Tours, and thence the machine flew direct to Kenley.

Colonel Beatty, who piloted the machine for the whole journey, was formerly at the Air Ministry in charge of the administrative work in connection with the School of Aerial Navigation, and he joined the No. 1 Communication Squadron especially to take part in the flight of the four British machines to Madrid. These flights have been arranged by the Air Ministry for demonstration purposes.

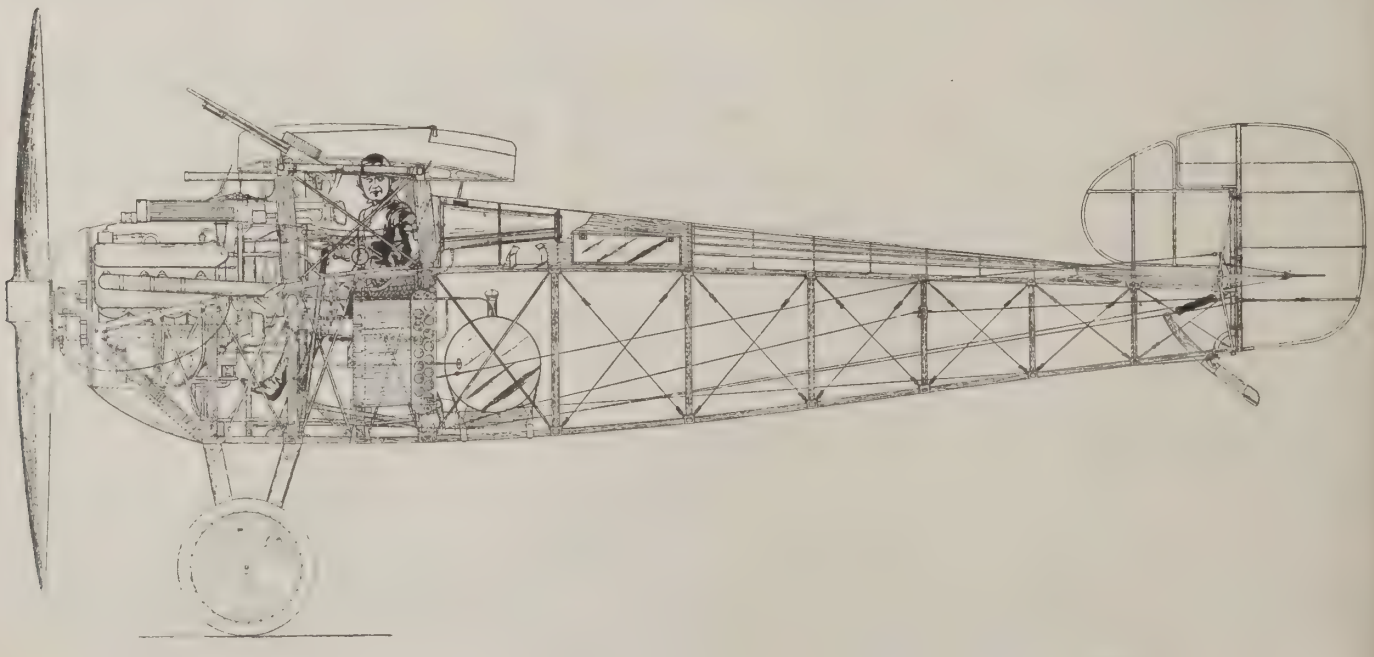
French Firm Builds Large Seaplane

It is probable that the first French machine to attempt a North Atlantic crossing will be a giant hydravion constructed near Bordeaux. Successful trials have already been carried out. It has a span of 23 metres, a length of 13 meters, and a central hull. It can carry 2,000 litres of petrol, and its motive power is a 500 h.p. Sunbeam, turning a four-bladed airscrew. Burrie, a pre-war aviator carried out the trials. It was constructed by Messrs. Bonneville, Musset, Dufau, Caussegne.

London Evening News Uses Regular Aeroplane Delivery

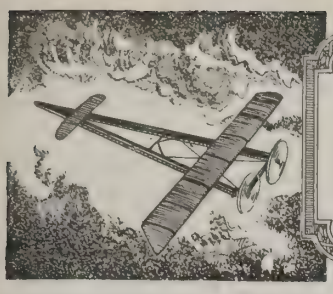
London.—The London *Evening News* is the first newspaper to establish its own aerial delivery. Mr. Sidney Pickles is the first pilot. A Rolls-Royce motored Fairey biplane is used which carries its cargo between Lambeth and Westminster bridges to the east coast.

Air Passenger Service



Madrid, May 30.—A company has been formed with Spanish capital to inaugurate a passenger, mail and merchandise aerial service between Madrid and several of the provincial capitals.

R-34 in 21-Hour Flight



London, June 1.—The airship R-34, after an adventurous trip in the sky extending over twenty-one hours, was able to descend safely at her destination at East Fortune, Haddingtonshire. It was expected that she would arrive at East Fortune within an hour or so, and food for the crew sufficient for only a short trip had been taken aboard. Two hours after the start the airship was over East Fortune, but owing to the haze it was deemed expedient that it should remain aloft.

From the North Sea a thick fog developed, and during the night the officers realized that they were completely lost. At last they found themselves twenty miles over the North Sea. Subsequently they reached the aerodrome and cruised overhead all night in the hope of landing in the morning. But the fog prevented this, so eventually they steered south.

In the afternoon, when the fog lifted, the R-34 was able to descend at her destination. The crew, after twenty-one hours in the air, were in a state of exhaustion from the want of food. The most troublesome passengers were three dogs and a cat who were manifestly uncomfortable the whole time.

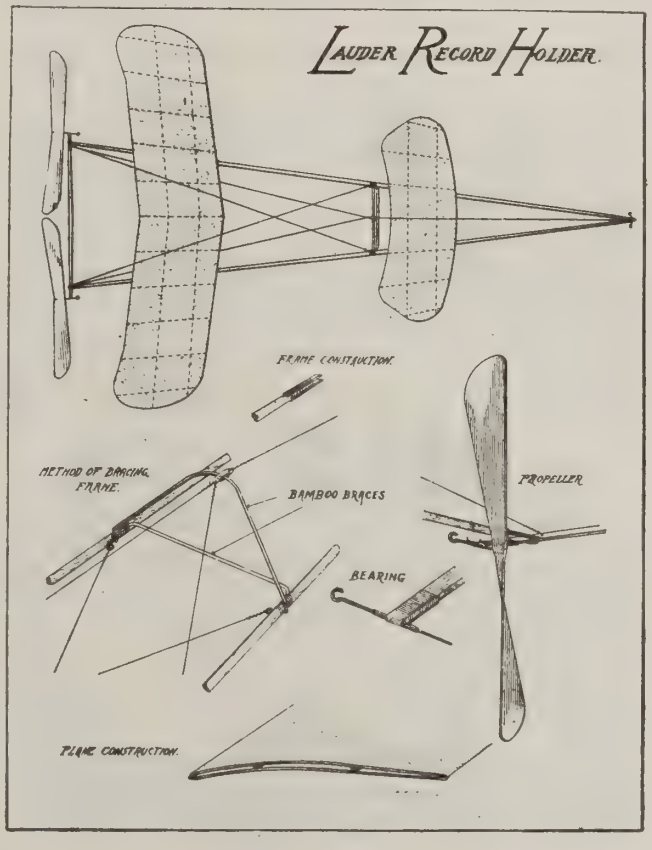
FOR the benefit of the less experienced model builders and for those who have written to me asking for dimensions of the Lauder Racing Model (which was a former record holder for distance, hand-launched) I am reprinting an article taken from an early issue of AERIAL AGE. Although this model was designed nearly four years ago, it is still in line with the models of to-day and with little practice and careful construction the model flyer can get wonderful results from it.

In order that those interested may obtain an idea of the constructional details that tend to make the model the wonderful flyer it is, we will attempt to give a very complete description of the model. Some time before the National Competitions were held the model made a flight of 195 seconds, this constituting a world's record for duration for this type of model. In the contests the model flew 3,537 feet, which is also a world's record for distance. It will therefore be noted that this model is both a distance and duration flyer, both qualities being seldom found in one model.



Reference to the accompanying drawings will give a clear idea of the constructional details.

The frame or fuselage consists of two side members 40 inches in length, of straight grained spruce. At the center each member is of approximately circular cross section, and is ¼ of an inch in diameter. The members taper to about 3/16 of an inch at the ends, the circular cross section being maintained throughout. The frame is braced by a strip of bamboo of streamline form, extending from one side member to the other, 18 inches from the apex of the frame. The ends of this brace are bent to run parallel to the side member of the frame, where they are secured by binding with silk thread and gluing. Piano wire hooks are also secured to the side members of the frame adjacent to the ends of the cross brace, and from these hooks extend wires of steel (No. 2 music wire), which run diagonally to the rear brace or propeller bar where they are secured. The frame is braced further by an upwardly arched strip of bamboo, as shown in the dawings, this strip being 2½ inches in height. At the top of this brace are two bronze strips of No. 32 gauge, one above the other, one on top of the brace and the other below. Adjacent to the ends of these strips of metal are perforations, through which pass bracing wires, one of which wires run to the apex of the frame, where a hook is mounted for its reception, and the other two wires extend to the rear of the frame where they are secured to the propeller brace. The propeller brace consists of a strip of streamlined spruce, 11¾ inches in length. The propellers being at an angle, clearance is allowed of ¼ of an inch wide at the center, tapering to 3/16 of an inch at the ends. The ends of the propeller brace extend out 1 inch from the side members of the frame to allow room for the rubber motors. In order to avoid slotting the ends of the side members of the frame so that the propeller brace can be secured therein, thin strips of bamboo are secured above and below the end of each side member—by binding with silk thread and gluing the space between these bamboo strips being utilized for the brace which is securely bound and glued therein. The propeller bearings consist of strips of very thin bronze (No. 32 gauge), about 3/16 of an inch in width, bent over ⅝-inch strips of German silver tubing, the tubing being soldered to the bronze strips and the propeller brace, which fits between the upper and lower portions of the bronze strips is securely bound and glued thereto.

The propellers are cut from solid blocks of pine, and are 12 inches in diameter. The blade, at its widest portion, measures 1⅜ inches. The blades are cut very thin, and in order to save weight, they are not shellaced or painted.

The propeller shafts of piano wire (No. 20 size) to fit the tubing used in the bearings, pass through the propellers and are bent over on the outer side to prevent turning. A few small bronze washers are interposed between the propellers and the outer ends of the tubing to minimize friction when the propellers are revolving. Twelve strands of rubber are used for each propeller, the rubber being ⅛ inch flat.

The planes are both double surfaced, and are of the swept back type. The span of the main plane is 28½ inches, with a chord of 6½ inches. The elevator has a span of 15 inches with a chord of 4¾ inches. The main plane has eleven double ribs, these ribs being built up on main beams of spruce, 1/16 x 3/16 inch, the front beam being placed 1¼ inches from the entering edge, and the second beam being 2 inches back from the front beam. The entering and trailing edges are formed from a single strip of thin split bamboo, all the joints being made by binding with thin silk and gluing. The elevator is constructed in like manner, except that it only has seven ribs, and the measurements are as above set forth. Both planes are covered with goldbeater's air "zephyr" skin, which is first glued in place and then steamed, and given a coat of a preparation used for this purpose.

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

They Took a Chance with Death

They took a death defying chance
Did Hawker and his mate
And with true sportsmen's spirits they
Gave no thought to the fate
That might o'er take them 'ere they reached
The goal they had in view
But trusted to the elements
And God to see them through.

They've set a record even if
The stake for which they played
Is lost for their brave death and the
Great task that they essayed
Has won the admiration of
The whole world and their fame
Will live fore'er, for they were not
Afraid to "play the game."

'Tis by such supermen as these
That daring deeds are done
They blaze a new trail here and there
And new records are won
And in the sporting world to-day
Many will emulate
The daring spirits of such men
As Hawker and his mate.

Owing to certain necessary preparations for the trans-Atlantic flight, Dad is going to have some water bill to pay next time
—By Fontaine Fox, in the N. Y. "Globe"

Everybody Can See It

"I don't like flying a bit," said pretty little Mrs. Newlyrich. "I know this aeroplane cost more than a limousine, but we've got to fly so high nobody can see it."

When is a Landing "T" Not a "T"

A humorous incident was brought to light by one of Souther Field Georgia's flyers in relating a trip taken in one of Uncle Sam's airships to a small town in support of the Victory Loan.

The most essential attribute to Aviation is a desirable landing field and an additional asset to a flyer is to know which way the wind is blowing, near the ground, for it is necessary in landing and taking off a ship to do so into the face of the wind.

On an active field strips of white canvas 12 feet long and 1 foot wide are laid out on the ground in the form of the capital letter "T" the top of the "T" facing the wind. The flyer upon seeing this from the air will be assured the direction of the wind.

Before starting on his trip the flyer has informed the Chairman of the Victory Loan Committee over the phone the necessity of a good landing field and also if possible he would appreciate their having a landing "T" on the Field. He was assured this would all be attended to. Upon arriving at the town, there, just on the outskirts, was a well-laid-out landing field; upon getting closer the pilot observed what appeared to be an immense cross standing upright in the center of the field. Someone had taken advantage of a large tree in the center of the field, had stripped it of its branches and then nailed a large board across the top of the tree; the whole thing painted white and this was a landing "T."

The pilot wrote a little note and dropped into the field saying, "I am very sorry but your field is too small to land in."

This enthusiasm and desire of all the southern towns to meet with every requirement of aviation is bound to have its effect, and we can readily predict that such towns as this, even though they make an innocent error the first time, will be eventually rewarded by being one of the regular stops on an aerial mail or passenger route.

—*Wilson.*

Double Crossed

"Ever study symbols?" asked the philosopher at the 'dome. "Funny thing the Huns put a cross on their planes, and that's what most of 'em got. The Allies put rings on theirs, and our flying men made rings round the Huns.

Wear Bathing Togs

Reporter: "You seem uneasy about the Atlantic trip, sir. May I ask the cause?"

Aviator: "It's this difference between the Newfoundland and the London time."

"How does that worry you?"

"I can't work out whether I ought to start in my evening togs or not."

Auroara

Alarmed passengers: "What was that terrible noise, Captain. Has one of the balloons burst?"

As a matter of fact, it was too true. But did that gallant old skipper lose his head? "Ladies and gentlemen," he said, "will you please return to your cabins. Everything is all serene on this airship. What you heard was the day breaking.—*Aircraft.*

Night Landing Apparatus to Indicate Distanch of Aeroplane from Ground

THREE searchlights, which are run by a fan generator attached to the aeroplane, make up the apparatus to indicate the distance of an aeroplane from the ground in night landing. Two searchlights, located under the extreme ends of the lower planes, project their rays perpendicularly to the line of flight, and in such a manner that they cross at a certain distance. A third searchlight located at the end of the fuselage projects its ray so that it crosses the others. Each light is mounted on a joint in such a fashion that it may be moved from side to side.

The regulating consists in giving to the searchlight such an angle that the three rays meet exactly on *O*, a point located slightly in front on the line of flight, so that when descending as the horizontal appearance is lost, the rays meet geometrically in front of the pilot, permitting him to see accurately the beacons which he should always keep in sight.

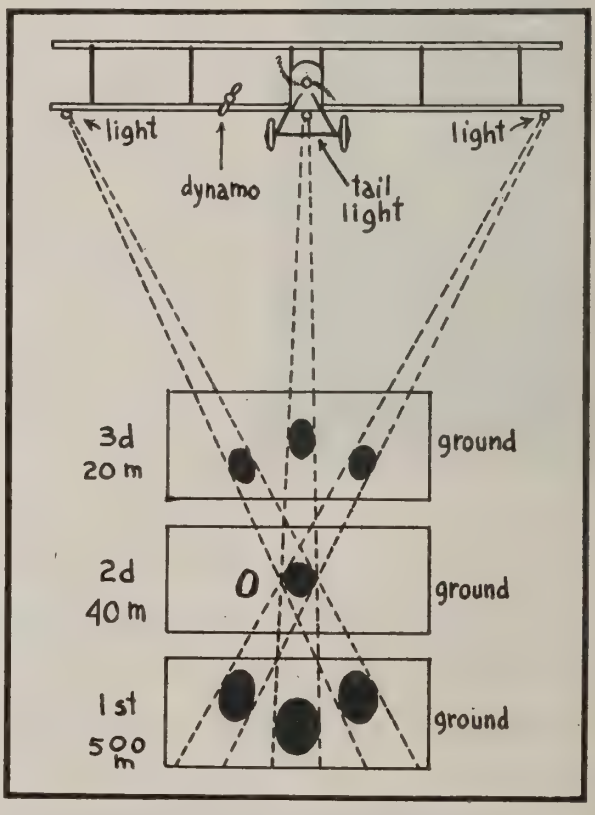

Diagram of the use of night landing lights

Its use is as follows: If, for example, the pilot is at an altitude of 500 meters, he prepares to land, he notes on his altimeter the precise altitude. He knows that from there it will take *T* seconds to get to the ground; and he has only to go through these few operations:

1.—He switches on the dynamo and commences to descend.

2.—He takes care that the ray of the rear searchlight (which at this altitude is ahead) reaches progressively point *O*, which has been calculated in such a manner that it is reached at 40 meters, for example.

Then the pilot knows that it takes *T* seconds to land, a time so short that he should straighten out his machine immediately.

The advantages are: 1—The machine does not require special construction to accommodate this apparatus. 2—It is neither bulky nor expensive. 3—It brings the pilot over point *O* from which he may land in a given number of seconds. 4—It is no bother (only the dynamo need be locked, the movement of the joints and connections trued up). 5—The same apparatus might be employed on seaplanes, as it is exceptionally hard to land them at night.—*Taken from "Eureka" —translated from "Tohtli."*

THE THOMAS-MORSE S-4 C SCOUT

FOR advanced training at nearly all of the Government fields the S-4 C Scout has become popularly familiar. For this stage of training the S-4 C has been used almost exclusively because of its ease of control and manoeuverability made possible by its small size, light weight per horse power and generously proportioned control surfaces.

The usual armament consists of a fixed Marlin or Browning machine gun, firing through the sweep of the propeller; an Adis telescopic sight mounted at the level of the pilot's eyes.

The stick type control is used; ailerons are operated by steel tubes run concealed in the upper plane, aft of the rear wing beam, similar to the French Nieuport Scout.

The S-4 C is suitable for use as a sport machine and for exhibition purposes. A front view of the S-4 C appeared in the March 24 issue of AERIAL AGE.

General Dimensions

Span	26′ 6″
Length	19′ 10″
Height	8′ 1″

Weights

Total weight, loaded	1,330 lbs.
Area, lifting surface (including ailerons)	234 sq. ft.
Loading per sq. ft. lifting surface	5.7 lbs.
Required horse power	90
Weight of machine loaded per horse power	14.8

Power Plant

Engine	Le Rhone (air cooled rotary) 80 H.P.
Engine R.P.M.	1,250
Fuel capacity	30 gal.
Fuel duration at full power	3¾ hours
Oil capacity	6 gal.
Oil duration at full power	4½ hours
Propeller, type	2 bladed
Propeller, diameter	8′ 0″
Propeller, R.P.M.	1,250

Landing Chassis

Type	"Vee"
Wheels	2 (tread 5 ft.)
Tires	26′ × 3″

Aeras of Control Surfaces (*Square Feet*)

Ailerons	25
Elevators	16.8
Rudder	8.5
Horizontal stabilizer	16.8
Vertical stabilizer	3.5

Performances

High speed	97 M.P.H.
Low speed	45 M.P.H.
Cilmb in first 10 minutes	7,500 feet

The Curtiss Model 18-B Biplane

(*Continued from page* 676)

ring surrounding the cockpit, and one which fires through an opening in the under side of the fuselage.

Landing Gear

The track of the landing gear is 59⅛″. Wheels, 26″ in diameter. The axle is located 44¾″ from the nose of the fuselage, and 49½″ below the center line of engine. With the machine in flying position, the center of gravity of machine occurs at a point 16.6″ behind the axle of landing gear.

When at rest on the ground, a straight line from the landing wheels to the tall skid makes an angle of 11° 15 minutes with the center line of thrust.

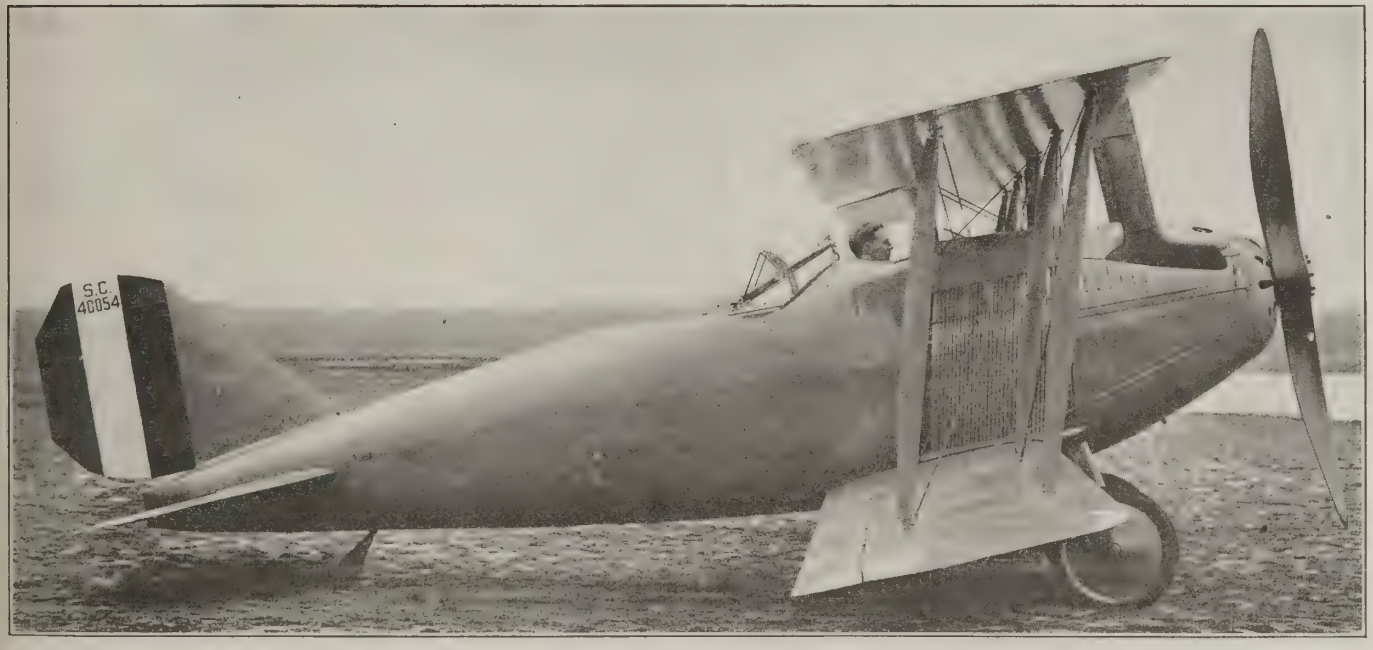
Tail Group

The triangular fin is 3′ in length and 3′ 6″ in overall height. Rudder, 46″ in overall height and 31 11/16″ in width. The stabilizer is divided at either side of fuselage. Maximum depth at the body, 2′ 5″. Maximum span overall, 10′ 10½″. Elevators are 18⅞″ in width.

Engine Group

The engine is a Curtiss Model K-12. A complete description of it appeared in the February 3, 1919 issue of AERIAL AGE. This engine is a 12-cylinder Vee Type with cylinders cast en bloc. Aluminum is used extensively in its construction.

Rated horsepower at 2500 R.P.M. of the crankshaft, 400. Bore and stroke, 4½″ by 6″.



Ignition is supplied by two high tension double spark six cylinder magnetos, located at the front end of engine and driven by beveled gears from vertical shaft through flexible couplings.

Two Duplex type carburetors are used. They are located between groups of cylinders. Carburetors are supplied with an auxiliary altitude hand-controlled air valve and also with non-back-firing screen.

Without oil or water, the Model K-12 weighs 680 pounds. Dead weight per rated horsepower, 1.70 pounds.

Gasolene is consumed at rate of .55 pounds per B.H.P. per hour; oil, .03 pounds per B.H.P. per hour.

The propeller is 9′ 0″ in diameter. In flying position, the tips of the propeller clear the ground by 8½″. When the machine is at rest there is a clearance of 17½″ between the propeller tips and the ground.

The Curtiss Model 18-B biplane with a 400 h.p. Curtiss Model K engine

(*Continued from page* 683)

from which departure was taken and course set for St. John's, N. F. Continued on this course until daylight, when land was sighted on the port bow. This proved to be Great Miquelon Island. Then skirted St. Pierre Island and proceeded up Placentia Bay.

"Radio communication was established with the U. S. S. Chicago and with various other ships and stations. Difficulty was experienced in receiving, due to much interference from the many stations all working on 600-meter wave length. The readings of the radio direction finder were followed for about two hours, when it became evident that certain errors existed. Comparisons of charts and visible land established the position of the C-5 to be in the extreme northern end of Placentia Bay.

Compass Readings Inaccurate

"Course for St. John's was set. This carried the C-5 over a railroad which was identified and followed. Air conditions were so rough that it was next to impossible to follow a compass course. At one point where the railroad forked the C-5 was brought low enough to inquire the proper direction to follow to St. John's.

"Continued along the line of the railroad to Topsail, Newfoundland; when departed from it and made for the sea outside the harbor of St. John's. Then came in over the harbor and landed at Pleasantville at 9:50 a.m., having been in the air for 25 hours and 50 minutes.

The Landing

"The overland trip over Newfoundland was under extremely rough air conditions and with a wind of about 40 miles an hour and stronger in the gusts. The general wind direction was west, though gusts seemed to come from all points of the compass. The landing at Pleasantville was perfect.

"Great credit is due Lieutenant Lawrence and Ensign Campbell, who made it. The ground crew, under command of Lieutenant C. G. Little, U. S. N. R. F., had been thoroughly instructed in their duties and carried out their part of the landing in a most satisfactory manner. Had such not been the case a wreck would probably have resulted at this time.

"After landing the C-5 was turned over to the ground crew, in charge of Lieutenant Little. The C-5 was secured and the work of refueling and gasing started. This was carried on only with great difficulty on account of the rolling and pitching of the C-5. The wind made it impossible to hold her steady.

C-5 Breaks From Moorings

"Every possible effort was made to hold the C-5, but this finally proved to be impossible and she broke adrift from her moorings. No possible precaution had been overlooked. The loss of the C-5 was wholly unavoidable.

"The total duration of the flight was 25 hours and 50 minutes. The distance covered was 1,022 sea miles, This distance takes no account of wide variations from courses caused by very bad air conditions. These variations undoubtedly greatly increased the actual distance covered, but no definite estimate is possible.

"During the flight to St. John's cold was the greatest discomfort, and even that was not really serious. Had the crew not been outfitted with flying suits completely lined with fur the cold would have been severe. As it was the greatest trial was that smoking is not carried on in a dirigible and nearly immediately upon landing every man was puffing away contentedly.

"Before starting from Montauk a supply of milk, chocolate, canned fruit, canned beans and thermos bottles filled with coffee and water had been put on board. Hardly a thing except the chocolate was touched during the flight, and only a part of that, though upon getting on board the Chicago all hands made up for missing meals.

"No hunger and thirst was particularly in evidence at any time while in the air. One member of the crew suffered a short attack of 'seasickness,' but no ill effects resulted. While in the air it was possible to crawl about the car, but as the air grew rougher little of this was done.

"For the most of the time the crew remained in their seats except as reliefs at the wheels changed or it became necessary to carry messages back and forth from the radio cockpit. Space was available in the radio cockpit for a man to curl up on the floor and sleep, but it was too cold and drafty for comfort. Dozing in the seats was far better.

"All told the discomforts were very slight and of no moment as compared with the general interest and experience of the flight."

Special Orders 123-124

(*Continued from page* 695)

The appointments of the following-named officers for the period of the existing emergency are announced:

To be colonels—Lieut. Col. Oscar Westover. Lieut. Col. James A. Mars, Lieut. Col. William F. Pearson.

To be lieutenant colonel—Maj. Horace M. Hickam.

To be first lieutenant—Second Lieut. John J. Redfield.

The following-named officers are relieved from further duty with the Spruce Production Division, Vancouver, Wash.:

Second Lieutenants Charles M. Commins, John A. Dolan, Alfred Gagnon, Isaac Lashua, Frank J. Hellman, William H. Taylor.

The following-named officers will proceed to Camp Pike, Ark.: Capt. Thomas J. Zimmerman, Second Lieut. Will G. White.

Second Lieut. Forrest D. Bradshaw will proceed to Godman Field, Camp Knox, Stithton, Ky.

The following-named officers are detailed for duty with the direction of the Director of Purchase, Storage and Traffic, Hoboken, N. J.: Capt. Clarence E. Osborne, First Lieuts. Daniel Crawford and John McGuire, Second Lieuts. Lloyd J. Peterson, Theodore B. Stutzman, Max W. Henney, John B. Shaver, Carl F. Kennedy.

Second Lieut. Rufus J. Pilcher will proceed to March Field, Riverside, Cal.

Second Lieut. William J. Davidson is detailed for duty with the Medical Department, and will proceed to Camp Lewis, American Lake, Wash., for duty in the base hospital.

Second Lieut. Leo A. Benoit will proceed to United States Naval Air Station, San Diego, Cal.

Par. 88, S. O. No. 119-O, May 21, 1919, relating to Second Lieut. Leland M. Baum, is revoked.

Par. 54, S. O. No. 103-O, W. D., May 2, 1919, relating to Capt. James A. Christie, is revoked.

The leave of absence granted First Lieut. Matthew H. O'Brien by Par. 130, S. O. No. 120-O, W. D., May 22, 1919, is extended five days.

Capt. William Winter will proceed to Hazelhurst Field, Long Island, N. Y.

The AIRCRAFT ADVERTISING AGENCY, INC. aims to cover the advertising field for aeronautics, including:

DISPLAY ADVERTISING for General Advertisers on Dirigible, Kite, and Spherical Balloons, Aeroplanes, Streamers from Aircraft, and by the dropping of Souvenirs and Handbills from the Air;

PREPARATION OF COPY and SKETCHES and the PLACING of ADVERTISING for manufacturers of Aircraft, Accessories, and Aviators' equipment, in aircraft and other periodicals.

AERIAL PHOTOGRAPHS of Cities, Summer Resorts, Country Places, Real Estate Developments, Etc.

(This Agency will be glad to hear from aviators and companies who have aeroplanes, or balloonists who have balloons, available for advertising purposes in any part of the country, and who are in a position to undertake and carry out business of this kind.)

THE ATLANTIC BRIDGED IN MAGNIFICENT NON-STOP FLIGHT

IN one straight flight the Atlantic has been crossed. The feat is the greatest sporting event the world has ever known, and from it the names Alcock and Brown will go down in history.

In commenting on the flight Henry Woodhouse, vice-president of the Aerial League of America, declared that the achievement of Captain Alcock and Lieutenant Brown was "the most stupendous feat of the age," and would advance the science of aviation to a degree not to be computed. One of the results that would be sure to follow within two years, he said, was that regular aerial express and passenger planes would be flying between the continents.

"It is the most stupendous achievement of the age," said Mr. Woodhouse. "Few persons, even those in the aeronautical movement, as we call it, believed that a frail thing of sticks and wood, canvass and wire could be capable of such a revolutionary achievement. Most persons, even some who had seen at close hand the remarkable progress of aerial science during the war, believed that the accomplishment of a non-stop flight across the ocean was at least five years off, and this opinion, which was held almost unanimous, adds even more credit to the gallant pilot and navigator of the Vickers-Vimy bombing plane. It is my confident belief that the names of Alcock and Brown, with that of Read and his gallant crew, will go down in history with that of Columbus as leaders of a new race of supermen and the leaders in a new era of communication between the continents.

"It is a stupendous thing to think of men launching themselves into almost limitless space in an aeroplane, which, after all, depends upon the success in flight more upon the confidence and belief of its pilots than upon any other factor. The aeroplane remains aloft and continues its terrific speed only so long as the nerve and endurance of the pilots remain unswerving .

"This flight advances the science of aviation at least five years and, I believe, opens the way to permanent aerial mail, passenger and express service between this country and England and all the other countries in Europe. We may look for swift journeys over the ocean to be almost as numerous as flights over the English Channel are to-day. Alcock and Brown flew across the ocean in a shorter time than it takes the fastest train to run from New York to Chicago, and the actual time of transmission of material objects from this country to Europe is cut more than one-fifth."

Discussing the outstanding features of the flight Mr. Woodhouse pointed out, first, the world will soon find a compensation for the extensive outlay of money and effort made during the war in the development of better and larger and safer aircraft.

Second, there are huge plans to be announced for the employment of aircraft for transportation and other utilitarian purposes, which are expected to go into effect this summer, and the performances which will result will astonish the world. Some of these plans have been under consideration in the United States, others in England, France and Italy, and aim to establish aerial lines throughout the world. The successful flight of Captain Alcock and Lieut. Brown will hasten their realization.

Third, Captain Alcock, Lieut. Brown and Commander Read and the gallant crews of the NC's have opened the trans-Atlantic airways, doing in fifteen hours more than the world's engineers did in years in opening a way from the Atlantic to the Pacific through the Isthmus or by the building of the world's greatest canals, tunnels, or bridges.

Fourth, one of the main factors which made for the success of this flight and which makes this flight conclusive evidence that aerial transportation is possible between the two continents commercially as well as scientifically is the fact that, owing to the great speed of the aeroplane, the flight was completed within the time representing the limit of human endurance. In subsequent flights pilots can probably cut down the time required to fly over the same route to twelve hours, thereby making it possible to use aircraft of the single-crew class for trans-Atlantic air lines.

Fifth, the flight of Captain Alcock and Lieut. Brown and the flight of Commander Read and his gallant crew have opened the way for flights direct from the United States to Europe, but to make these flights without stop it will be necessary to have aeroplanes at least twice as large as the largest aeroplane at present under construction.

Sixth, Ireland is destined to become one of the world's greatest airports, where trans-Atlantic air lines will land to refuel before continuing their journey.

Seventh, too much cannot be said of the reliability of the motors used in this flight, which, combined with the skill and daring of the aviators and the reliable instruments for navigation, opened an entirely new epoch in aeronautics and permit planning the use of aeroplanes for transportation over long distances, where the tremendous speed of aeroplanes can solve difficult problems of transportation.

Comments on the Flight

Alan R. Hawley, president of the Aero Club of America, called it a "magnificent flight!" He said: "We are glad to see that the land planes are able to fly nearly 2,000 miles where it would be impossible to make a landing. This means they can fly to any part of the world almost under any circumstances. No doubt Alcock and Brown will receive the *Daily Mail's* $50,000 prize—and they well deserve it."

Augustus Post, secretary of the Aero Club, said:

"We are delighted at the success of Captain Alcock's flight. We have already seen what the seaplane can do, and this flight of Alcock's shows how tremendous are the possibilities when we can use land planes to cross the ocean. I have no doubt that when the American army land plane starts its flight from the Atlantic to the Pacific it will go through without a hitch."

"It was a wonderful feat," said Secretary Daniels. "I congratulate Mr. Alcock and rejoice with him. His flight is indicative of the great things that are ahead in aviation."

Rear-Admiral David W. Taylor, chief naval constructor, who is conceded to have been the "father" of the American plan to cross the sea in an airship, also expressed his admiration of the pluck of the two British aviators.

"I am heartily glad they made it," he declared. "It means that long-distance flying will become immediately more popu-

lar and we can expect other record-making trips."

"I am pleased to hear of the successful negotiation of the second stage of the progress in trans-Atlantic flight," said Glenn H. Curtiss, pioneer aviator and builder of the NC-4, the first heavier-than-air craft to cross the Atlantic. "The crossing with our seaplane with one stop in midocean was the first stage. This flight without stop is the second. The third will be the crossing with a useful load abroad. With the culmination of that event commercial aviation as applied to overseas flight shall have been accomplished.

"Naturally, I prefer the seaplane for the trans-Atlantic flight to the plane designed primarily for land flights. In the first place, there is always the difficulty of taking off from the land, as has been very clearly demonstrated by all of the flights which have been attempted in Newfoundland. According to reports from St. John's the Vickers had a hard time leaving the ground with the heavy load it carried. The Martinsyde crashed when it struck a small bump in the earth.

"The flight of our three NC planes showed, much to the surprise of many persons, that machines of that type are able to stand a great deal of punishment from rough seas. With some improvements suggested to us by experience they will be capable of riding out reasonably rough weather.

Third Stage Within a Year

"Aviation is developing faster than could with reason be hoped. Within another year we shall have accomplished the trans-Atlantic flight with a useful load, thus reaching the third stage of overseas aeroplane development.

"I shall cable my congratulations to Captain Alcock and Lieut. Brown."

"One great stunt," was the comment of Lieut. Commander Albert C. Read of the American seaplane NC-4, the first to cross the Atlantic, on the successful flight of Captain Alcock and Lieut. Brown.

"While there is nothing which will add much information to the art of aviation as a result of the flight," he continued, "it was a wonderfully nervy thing to attempt and a magnificent achievement. I have much admiration and respect for the men who attempted the great feat in face of such odds. It required a machine built of the best material, but, above all, staunch determination and unflinching courage. They also made the attempt at the right time."

Commander John H. Towers of the NC-3 said:

"It was a splendid feat."

GREATER NAVAL AVIATION APPROPRIATION URGED

URGING that Congress appropriate $45,000,000 for naval aviation during the next fiscal year and declaring that $36,000,000 is the very lowest figure that should be appropriated, if the American Navy is not to fall behind, Secretary Daniels sent to Senator Carroll S. Page, Chairman of the Naval Committee, a letter urging an increase in the $15,000,000 appropriation granted by the House.

Secretary Daniels informed Senator Page that if the appropriation should remain at $15,000,000 this country could only "mark time" in aviation, when it should be leading.

Great Britain and France are going ahead with plans for aviation development on a large scale. Great Britain has made available for the current year an appropriation of $320,000,000 for army and navy aircraft development, and France $200,000,000. The American Government is behind in lighter-than-air development. It has no rigid dirigibles. The British Government is going in strongly for the development of large rigids. The rigid dirigible R-34, which is soon to leave England for a round trip trans-Atlantic flight, is part of the British development.

Secretary Daniels' letter follows:

"My Dear Senator:

"The Naval Bill as reported to the House has cut the appropriation for Navy Aviation to $15,000,000. I deem it my duty to bring to your attention the fact that with this amount Navy Aviation will practically 'mark time' during the next year, which should be a year of rapid development, and will be a year of rapid development of this arm of the Navy in countries other than the United States. This is sufficiently indicated by the fact that in Great Britain the appropriation for aviation made for the current year amounts in round figures to $320,000,000. This includes all aviation for military purposes, and should, of course, be compared with the total contemplated appropriations for both Army and Navy in the United States, amounting to something like $30,000,000.

"The General Board of the Navy, after extended hearings covering the whole field of aviation, recommended a program for the next fiscal year which our experts estimated would require the $45,000,000 originally asked for by me in Congress. I feel very strongly that the figure of $36,000,000 reported by the Senate Naval Committee during the last session should at least be provided if we are to make any approach to the aviation activities and development considered necessary by the General Board.

"It will be recalled that in 1909 the feat of Bleriot in flying across the English Channel in a plane propelled by a motor of about 25 H.P. was regarded as miraculous. In ten years the development of heavier-than-air craft has been so remarkable and progressive that recently we have seen our multiple-engined NC-4 successfully completing a voyage from New York to Plymouth by way of Newfoundland, the Azores and Portugal. We are now expecting a visit from the British Rigid R-34, which is to make the attempt to fly directly from England to the United States. The performances of this British Rigid to date indicate the practicability of a voyage, and even should the present attempt fail by some mischance, there is every prospect that the voyage will soon be successfully accomplished.

"These long voyages have demonstrated beyond doubt the practicability of the large lighter-than-air ship. There can be no doubt in the mind of any one that aviation is destined to assume a role of tremendous importance in the affairs of the world. At present the largest field for aircraft is the military one, and by the rapid development of such aircraft only is it practicable to reach a condition of commercial application.

"I feel sure you will agree with me that the United States, where was built and operated the first successful flying machine, which under the stress of war has made supreme effort during the past two years and is now, broadly speaking, abreast the rest of the world in aeronautical development, and ahead in some respects as instanced by the successful voyage of the NC-4 should not now falter and fall by the wayside in aviation.

"I regret to inform you that an appropriation of $15,000,000 will not suffice to permit the construction of large rigids in this country, and possibly it will not even allow the beginning of a 'rigid' program. There is not on this continent at this time a dirigible hangar large enough to house the English R-34, and the visit of that vessel to our shores must be curtailed because of the possibility of the ship being wrecked in the event of occurrence of bad weather.

"The rigid dirigible has been of splendid service during the war. Both Germany and Great Britain used them successfully. Admiral Jellicoe stated that a rigid dirigible was worth two light cruisers, and it is of interest to note the statement of the British Admiralty to the effect that at the battle of Jutland the German fleet, though inferior in numbers, was able to escape complete destruction because of the good use of its scouting airships. It may be of interest to you to know that inquiries are now being made on the part of the British Government as to the possibility of a hangar for rigids being allowed in this country for use by a foreign-owned Zeppelin employed commercially.

"I will not dwell on the part played during the war by aircraft in patrolling our own coast and the coasts of our Allies, but I wish to invite your attention particularly to the importance of aircraft operations with the fleet.

"Spotting from aircraft increases the gunnery efficiency at long ranges tremendously, and gunnery efficiency perhaps is, more than anything else, the real measure of efficiency of the fleet. Several times in our recent fleet exercises low visibility or smoke screens absolutely prohibited spotting from ships, and all spots had to be taken from the spotters in the aircraft overhead. The improvement in the ability to spot is one of the compelling reasons for shooting at longer ranges. A naval action undoubtedly will be begun in clear weather at ranges of over 20,000 yards and spotting from high in the air will be of paramount importance.

"In the British fleet planes are now carried on all battleships as well as in special vessels intended to convey them. Aviation is recognized as a definite and permanent part of the fleet.

"As regards the large flying-boat type, we are in a reasonably satisfactory position, but the type must be further developed and will be during the year if money is available. As regards aeroplanes for regular use of the fleet, a recent development, and one which, as indicated, is essential for fleet efficiency, we should take the matter up vigorously at once, install the best type of such craft now available, and keep the installation up to date as the art develops. As regards lighter-than-air craft, we are ready to build on a reasonable scale on practically equal terms with the rest of the world. The type is sufficiently developed to warrant building in reasonable numbers, and in the judgment of the military experts of the Department, the prompt development of the lighter-than-air craft is of the utmost importance.

"Sincerely yours

"Josephus Daniels."

The News of the Week

Aerial Commuters From Down-town New York Taken to Country Homes in Flying Boats

New York, N. Y.—Inaugurating a commuters' aerial service, Mr. Edmund Randolph, broker, and Mr. R. W. Allen were taken to their homes by Curtiss hydro-aeroplanes at Locust Valley and at Great Neck Bay, L. I., respectively, from off the Battery. Mr. Allen was piloted to his home by his son, Captain A. Livingston Allen, in less than thirty minutes. The time of travel was thus cut to less than half and the comfort and convenience of travel greatly increased. It is predicted that this means of travel will be utilized by several business men whose offices are in downtown New York within a few weeks.

Boston to New York in One Hour

Lieutenant Colonel Leonard H. Drennan, Air Service officer of the Northeastern Department, made a record flight between Boston and New York in a De Haviland Four, flying from Boston to Hazelhurst Field, L. I., a distance of 175 miles in 83 minutes, thus averaging over two miles a minute. Lieutenant Willis R. Taylor accompanied him as a passenger.

Utica Newspaper Delivered by Aeroplane

Utica, N. Y.—The Utica *Daily Press* is arranging with the Mohawk Valley Aeroplane Corporation for the delivery of its special aeroplane edition to Old Forge and the surrounding districts.

Navy Plans Include Around-the-World Flight

Washington, D. C.—In discussing plans for the reception of the British dirigible R-34, which is expected to reach this country within ten days, an official high in naval aviation circles declared that the Navy's plans for developing lighter- than-air travel had not stopped short of the possibility of a round-the-world flight in a dirigible.

In discussing the Naval aeronautic program, Secretary Daniels intimated that a trans-Pacific flying boat trip has been contemplated.

Aerial Express Service Between Allentown and New York in Operation

Arrangements have been completed between Philip W. Blake, executive secretary of the Allentown (Pa.) Chamber of Commerce and Lieutenant Morse D. Levitt of the American and Canadian Allied Flying Circus, Inc., of 1482 Broadway, N. Y., for the operation of a regular aerial express to make aeroplane deliveries of merchandise from the New York market for the merchants of Allentown. This will probably be the first aerial express service in operation on a co-operative basis.

The consignments of goods are shipped from the Central Park, L. I., field of the flying circus and consist of assorted merchandise. The aeroplane lands at the Allentown Country Club, on the outskirts of the town. Lieutenant Franklin F. Snyder, who has spent two years in the air service, was the pilot on the first trip.

Alliance Single Motored Plane Entered in Trans-Atlantic Contest

The latest entry for the trans-Atlantic flight is the "Sea Bird" of the Alliance Aeroplane Co., a company controlled by Waring and Gillow. It has been built from the design of Mr. J. A. Peters, who will pilot the machine across the Atlantic and is a single-seater biplane with a 450 h.p. "Lion" Napier engine. The machine is illustrated on this page, which shows the comfortable accommodation provided for both pilot and navigator. The machine is fitted with wireless, having a transmitting range of 250 miles, and a receiving range of 2,500 miles, and a directional installation by means of which the navigator will be able to be in direct communication with the compass stations both in Newfoundland and Ireland at any time during its flight, and can accordingly set his course independently of other means. The main particulars of the "Sea Bird" are as follows: Span, 53 ft.; length, 33 ft. 6 ins.; area, 700 sq. ft.; total weight, 7,400 lbs.; petrol, 500 gals.; oil, 50 gals.; range, 3,000 miles; max. speed, 140 m.p.h.; landing speed, 45 m.p.h.; engine, 450 h.p. Napier.

Aerial Landing Field Established at Oklahoma City

Oklahoma City.—A forty-acre landing field, known as Westwood Field, has been in operation for several months. It is located in a suburban section of the city, convenient to rail and street car transportation.

Hangar erected by Alfred Decker & Cohn, for two Curtiss JN-4D-2 aeroplanes, used in a regularly-scheduled delivery service

Chicago Clothing Distribution by Aeroplane Follows Regular Routes

Chicago, Ill.—The aerial delivery service for Alfred Decker & Cohn, Chicago clothing merchants, was inaugurated on June 3. A 40-acre field at Maywood is the headquarters of the express system and two Curtiss JN-4D-2 aeroplanes piloted by Lieut. David L. Behncke form the original equipment.

The first week's schedule included trips to the leading colleges and universities in the Middle West. Routes have been laid out between Chicago and Madison, Wis.; Chicago and Galesburg; Chicago and Champaign, Ill.; Chicago and South Bend, Ind., and Chicago and Lafayette, Ind.

The Chicago-Madison route includes stops at Beloit College and the University of Wisconsin; the Chicago to Galesburg route takes in Knox College; the Chicago to Champaign route takes in the University of Illinois; the Chicago to Lafayette route takes in Purdue University, and the Chicago and South Bend route takes in Valparaiso University and the University of Notre Dame.

Leaving Chicago at 12 o'clock, the aeroplanes reach Kankakee, Ill., forty-five minutes later. They leave Kankakee at 2:30 and an hour later deliveries are made in Champaign.

Lincoln Aero Club, of Nebraska, Affiliates With Aero Club America

The Lincoln Aero Club of Nebraska, with its headquarters at Lincoln, was accepted into affiliation by the Aero Club of America at a meeting held June 4.

It held its first banquet on April 2, at which over two hundred people were present, and the prospects are for the working up of a very enthusiastic aeronautic contingent in Lincoln.

The appointed officers of the Lincoln Aero Club of Nebraska are as follows: President, Raymond R. Farquhar; First Vice-President, Phil L. Hall, Jr.; Second Vice-President, Leo Fahlman; Secretary, Abe D. Zook; Treasurer, S. J. Dunn; Chief Engineer, H. B. Wild.

The insignia of the Lincoln Aero Club of Nebraska is most appropriate, being that of a winged head of Abraham Lincoln.

It has followed by-laws of the Aero Club of America as its constitution and has six classes of membership, i. e., honorary, collegiate, life, army and navy, resident and non-resident.

Articles of incorporation of the Lincoln Aero Club of Nebraska were filed in the office of the Secretary of State, State of Nebraska, on the first day of April, A. D. 1919.

American Medical Association Convention Discusses Medical Aspects of Aviation

Atlantic City, N. J.—Physicians outlined plans to aid fliers at a meeting held on June 13. The first society in the United States to lay down what are said to be scientific and accurate tests to determine the abilities of an airman organized and elected officers. The organization is the outgrowth of the American Medical Association convention.

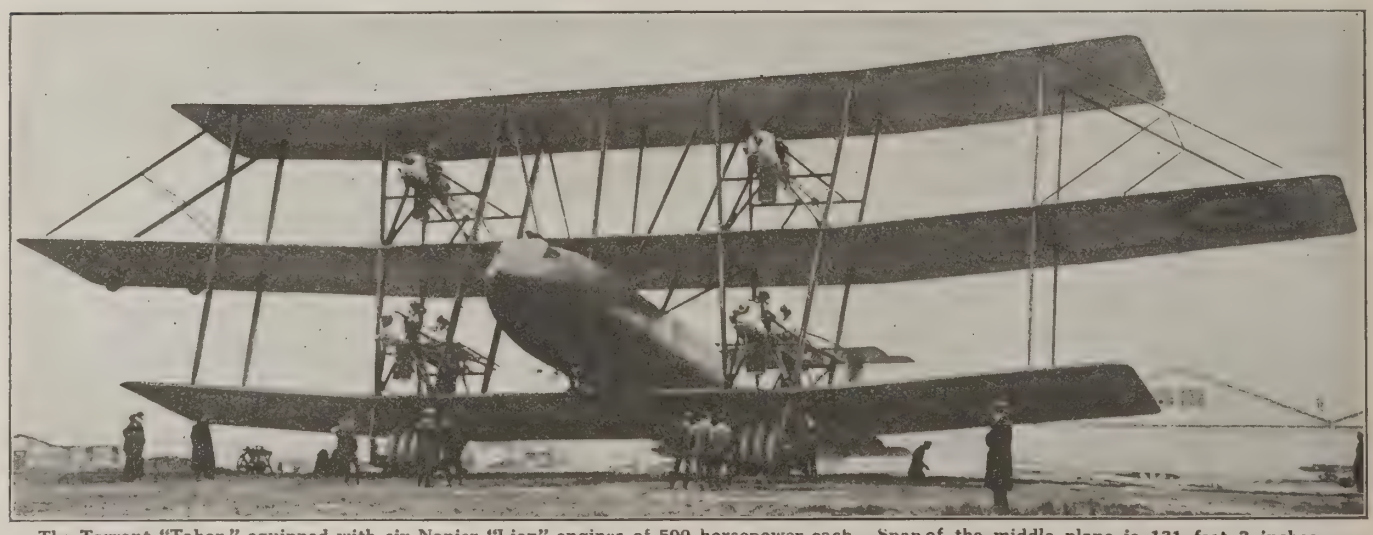
This body will help the Government in taking and maintaining the air supremacy of the world, according to Colonel John O. McReynolds, Dallas Tex., who was elected president of the newly formed Air Service Medical Association.

It is planned to popularize flying, and it is expected thousands will become aviators, he said. Tests will be made to determine the special work for which each is fitted, the height to which he may safely ascend, and details of a similar nature.

The first aeroplane ambulance seen in Atlantic City arrived here on June 13 from Mineola, L. I., after a flight of 118 miles in 80 minutes. It bore a medical man coming here to attend the convention of the American Medical Association, the first to arrive by this route.

The plane is used in army hospital work, and the trip was made to demonstrate the value of the army medical equipment under special permission of the government. Lieutenant W. F. Sharon was the pilot and Flight Surgeon L. R. Burnett traveled as a passenger.

A sick or wounded soldier can be carried in a compartment in the rear of the plane in absolute comfort with room for the surgeon to attend him. The patient lies on a Stokes litter, a single wire held in by specially arranged webbing belts. He is placed on the bed through an aperture in the lower part of the fuselage of the plane.



De Hart and Budwig Carrying Passengers from New York City Field

New York, N. Y.—Dana C. De Hart and Gilbert C. Budwig have started a passenger-carrying service from their flying field at Hillside Drive and North Westland, Queens, N. Y. Both the aviators were employed as civilian instructors throughout the war, and since that time have been in the aerial mail service. Curtiss biplanes are used, which are inspected before each flight. All passengers are insured to the extent of $1,000.

Aerial Map of Fort Sill-Oklahoma City Route Being Made

Oklahoma City.—An Army photographic squadron is making a huge photographic mosaic of the route between Fort Sill and Oklahoma City, covering a strip eighty miles long and twenty miles wide. Thirty thousand plates will be exposed and when completed the map will be 76 feet long and 16 feet wide.

The squadron has established its headquarters at Westwood Field, and is in charge of Lieut. L. M. La Plant, and consists of four pilots, three observers and six enlisted men.

The Tarrant "Tabor," equipped with six Napier "Lion" engines of 500 horsepower each. Span of the middle plane is 131 feet 3 inches. Overall height is 37 feet 3 inches. Overall length, 73 feet 2 inches. Total weight, 45,000 pounds

VICKERS-VIMY BIPLANE MAKES FIRST NON-STOP TRANS-ATLANTIC FLIGHT

BY successfully flying across the Atlantic from St. John's, Newfoundland, to Clifden, Ireland, Capt. John Alcock and Lieut. Arthur W. Brown, pilot and navigator of the Rolls-Royce motored Vickers-Vimy biplane, are the winners of the *Daily Mail* $50,000 prize. The flight of approximately 1,960 miles was completed in 16 hours and 12 minutes, averaging nearly 120 miles an hour.

The report of Alcock and Brown to the Aero Club was as follows:

"Landed at Clifden at 8.40 A.M., Greenwich mean time, 15th of June, Vickers-Vimy Atlantic machine leaving Newfoundland coast at 4.28 P. M., Greenwich mean time 14th of June. Total time, 16 hours 12 minutes.

ALCOCK & BROWN."

But the brief and modest description which comes from the airmen at Clifden tells of an adventurous and amazingly hazardous enterprise. Fog and mists hung over the North Atlantic and the Vickers-Vimy biplane climbed and dived, struggling to extricate herself from the folds of the aeroplane's worst enemies. On one occasion she rose to 11,000 feet and swooped down almost to the surface of the sea, and at times the two voyagers found themselves flying upside down.

Before coming to earth near the Clifden wireless station Alcock circled the wireless aerials, seeking the best spot to reach the earth, but no suitable ground was found, so he chanced it in a bog.

The wireless staff rushed to the aid of the aviators. They found Brown dazed and Alcock temporarily deafened by the force of the impact.

Captain Alcock's first interview on the flight as published in the *Daily Mail,* is as follows:

"We have had a terrible journey. The wonder is that we are here at all. We scarcely saw the sun or the moon or the stars. For hours we saw none of them.

"The fog was very dense and at times we had to descend to within 300 feet of the sea. For four hours the machine was covered in a sheet of ice, caused by frozen sleet. At another time the fog was so dense that my speed indicator did not work, and for a few seconds it was very alarming.

"We looped the loop, I do believe, and did a very steep spiral. We did some very comic stunts, for I had no sense of the horizon.

"Winds were favorable all the way, northwest, and at times southwest. We said in Newfoundland we would do the trip in sixteen hours, but we never thought we should. An hour and a half before we saw land we had no certain idea where we were, but we believed we were at Galway or thereabouts.

"Our delight in seeing Eastal Island and Turbot Island, five miles west of Clifden, was great. People did not know who we were when we landed and thought we were scouts on the lookout for the Vimy.

"We encountered no unforeseen conditions. We did not suffer from cold or exhaustion, except when looking over the side. Then the sleet chewed bits out of our faces. We drank coffee and ale and ate sandwiches and chocolate.

"The flight has shown that the Atlantic flight is practicable. It should be done not with an aeroplane or a seaplane but with a flying boat.

"We had plenty of reserve fuel, using only two-thirds of our supply. The only thing that upset me was to see the machine at the end get damaged. From above, the bog looked like a lovely field, but the machine sank into it up to the axle and fell over on to her nose."

Mists robbed the night of the advantage of the full moon and the propeller of the generator for wireless apparatus was torn away by the wind soon after the start. So the two aviators were thrown upon their own resources. The skilful navigation which brought the machine near to the center of the Irish coastline was one of the finest features of the flight. Before starting on the flight Lieut. Brown had stated that an effort would be made to land at Clifden, and his success in attaining his objective despite the handicap due to impossibility of making observations from the stars or to use the radio equipment, is a remarkable feat of navigation.

The unbroken silence of the Vickers radio had caused apprehension, not only among the ships far flung across the Atlantic which had been listening for word from the pioneer, but also among thousands on both sides of the ocean who had waited expectantly for some flash of news from the speeding 'plane.

THE GENERAL PROPERTIES AND USES OF PLYWOOD

By B. C. BOULTON, B. S., A. E.

FOR a material combining lightness and strength, wood would be unexcelled if it were of homogeneous structure. In tensile strength parallel to the grain, certain heavy woods like pignut hickory are more than half as strong as mild steel, and their weight is less than one-eighth that of steel. Spruce, a typical light wood, has a fifth the strength of steel, yet only an eighteenth its weight. The same is true, though to a less degree, of the modulus of rupture, and the compressive strength of wood parallel to the grain. However, the tensile and crushing strength perpendicular to the grain, and the modulus of elasticity in this direction, are but a tenth to a twentieth of these values. On the other hand, the resistance of wood to shear parallel to the grain is many times less than its resistance to shear across the grain. Because of these facts, the utilization of the full tensile strength of wood, or of its high modulus of rupture, is made difficult. This is due to the trouble in holding a member by bolts or similar means, to the large bearing surface necessary to prevent crushing of the wood perpendicular to the grain, or to weakness in horizontol shear.

The chief function of plywood is to equalize the strengths of wood in directions at right angles to each other. This is accomplished by cutting the wood into thin sheets, called veneer, which are then glued together to form a laminated structure, composed of a central core, or cross-band, on both sides of which are glued sheets of veneer with their grain at right angles to that of the core. These are the outside or face plies in three-ply panels. In multi-ply construction the procedure is the same, except that extra plies are added, an equal number on each side of the core, and every ply is placed with its grain at right angles to that of the layer immediately beneath it.

Another very important result obtained by plywood construction is the practical elimination of warping. In ordinary wood, changes in its moisture content produce shrinkage, which is much greater, proportionally, in a direction transverse to the grain than parallel to it. When this shrinkage is unequal on the two faces of a board, owing to more rapid alteration in moisture content on one side, warping occurs. By making the shrinkage in one direction oppose that in the other, properly constructed plywood prevents the difficulties caused by shrinkage. In the more extended discussion that follows is explained the manner in which plywood modifies the properties of natural wood.

Woods Used in Plywood Construction: On account of the many new uses to which plywood has been put during the war the varieties of woods employed in its manufacture have changed considerably. Extensive testing has brought about the elimination of some species, because of their lack of suitability for structural purposes, and has caused the selection of several of the little used woods for special work.

The species from which most plywood was made before the war are given below, in the approximate order of their importance: Gum, maple, oak, poplar, ash, basswood, birch, elm, walnut, beech, yellow pine, cottonwood, sycamore, and mahogany. Several woods, notably spruce, Spanish cedar, and redwood, which formerly were seldom used, have been found to be among the best for meeting the requirements of aeroplane construction. The more important properties for structural plywood are lightness combined with high bending and compressive strength, stiffness, and toughness or resistance to splitting. Other qualities which are desirable, but which do not vary greatly in different species, are resistance to distortion, due to variation in moisture content, and ability to take glue well.

Some aeroplane parts call for a very strong, tough wood, and one of the heavier species, like birch or maple, must be employed; while other parts require the qualities of lightness and stiffness together with moderate strength, such as is found in varying degrees in spruce, poplar, basswood, and Spanish cedar.

Factors in the Design of Plywood

Symmetrical Construction: The first principle governing the construction of plywood is that of symmetry. On either side of the center layer or core there must be an equal number of plies. The number of laminations in plywood must therefore be always odd. For each ply on one side of the core there must be a corresponding ply in the same relative position on the opposite side of the core. Both such plies must be of the same thickness and same species of wood, preferably, cut in the same manner, that is, by a rotary cutter, slicer, or veneer saw. Furthermore, the grain of two layers, which are both the same distance from the core, must run in the same direction. The reasons for this manner of construction are in the main connected with the phenomena of shrinkage.

On account of the great difference, with any wood, between the shrinkage parallel to the grain and that perpendicular to it, stresses will always be set up or released in plywood when its moisture content is altered. Considering a three-ply panel, for example, if the humidity increases the core will tend to expand transversely, but since it is rigidly glued to the face plies, in which the grain is at right angles to that of the core, this transverse swelling is checked, on account of the fact that the face plies do not deform appreciably in a direction parallel to their grain. They are therefore put in tension. In a similar way the face plies would expand in a direction perpendicular to their grain were they not restrained by the core, thereby being put under compression. Each one of the three plies is thus subjected to tensile stresses parallel to its grain, and to compressive stresses transverse to its grain.

The application of the principle of symmetry will prevent warping, for it is evident that if the face plies, or with multiply wood all pairs of corresponding, intermediate plies as well, are of the same thickness density and species, and have their grain running in the same direction, the stresses on either side of the core will be balanced. However, should similarly situated plies be of unequal thickness or character, or not have their grain parallel, either cupping or twisting of the panel will occur. Because of these facts, it is clear that in sanding plywood care must be exercised to sand both faces equally.

An extreme example of distortion results when one of the faces of a thin, three-ply panel has its grain perpendicular to that of the other face ply. If such a panel is dried, it will curl up almost into a cylinder with the ply, whose grain is parallel to the grain of the core, on the inside. This phenomenon is produced by the unsymmetrical distribution of the shrinking stresses. Placing the grain of each face ply at an angle of 45° to that of the core and of 90° to that of the other face ply, will cause another extreme case. A change in moisture would bring about a twisting or curling up of such a panel in the direction of one of its diagonals.

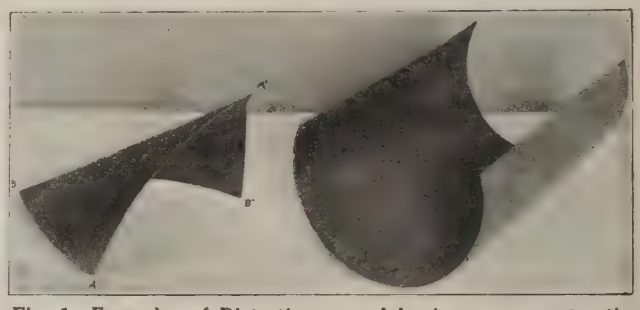

Fig. 1—Examples of Distortion caused by improper construction

Fig. 1 shows both types of deformation, and Fig. 2 the manner in which the amount of distortion is measured.

This discussion makes evident the necessity for having the grain of adjacent plies as exactly at right angles as is practical. Furthermore, to reduce shrinkage stresses to a minimum, it is desirable that the moisture content of the plywood, when the latter is removed from the clamps after gluing, be as closely as possible the same as it will be in actual service.

Owing to the fact that the shrinkage of different varieties of wood, with the same alteration in moisture content, is never identical, the amount of shrinkage in a panel will vary with the species or combination of species used. It is also dependent on the relative thickness of the different plies and the number of plies. A series of 54 shrinkage tests were made recently by the Forest Products Laboratory on combinations of ten of the more common species of wood. The average shrinkage in bringing the panel from the soaked to the oven-dry condition was .45 per cent parallel to the grain and .67 per cent perpendicular to it. Individual results ranged from .2 to 1.0 per cent, and from .3 to 1.2 per cent, respectively. These values should be contrasted with shrinkage, under the same conditions, of 8.5 per cent for flat-sawn boards and 4.5 per cent for quarter-sawn lumber, which are average values for 150 species.

Number of Plies: Several factors must be considered in determining the number of plies it is best to use. The most important effect of increasing the number of plies is to make the plywood more homogeneous. Its strength in both bending and tension in the direction of the grain of the face plies is decreased, while its strength in a perpendicular direction is raised, until the strengths in each direction are nearly equal. Hence, the three-ply type is best if much greater strength is desired in one direction than in another. Approximate equalization of the strengths of a three-ply panel in each direction can also be accomplished by properly proportioning the core thickness. However, in resistance to splitting action, such as is needed when plywood is fastened by screws near its edges, the three-ply can never be made to equal the multi-ply construction.

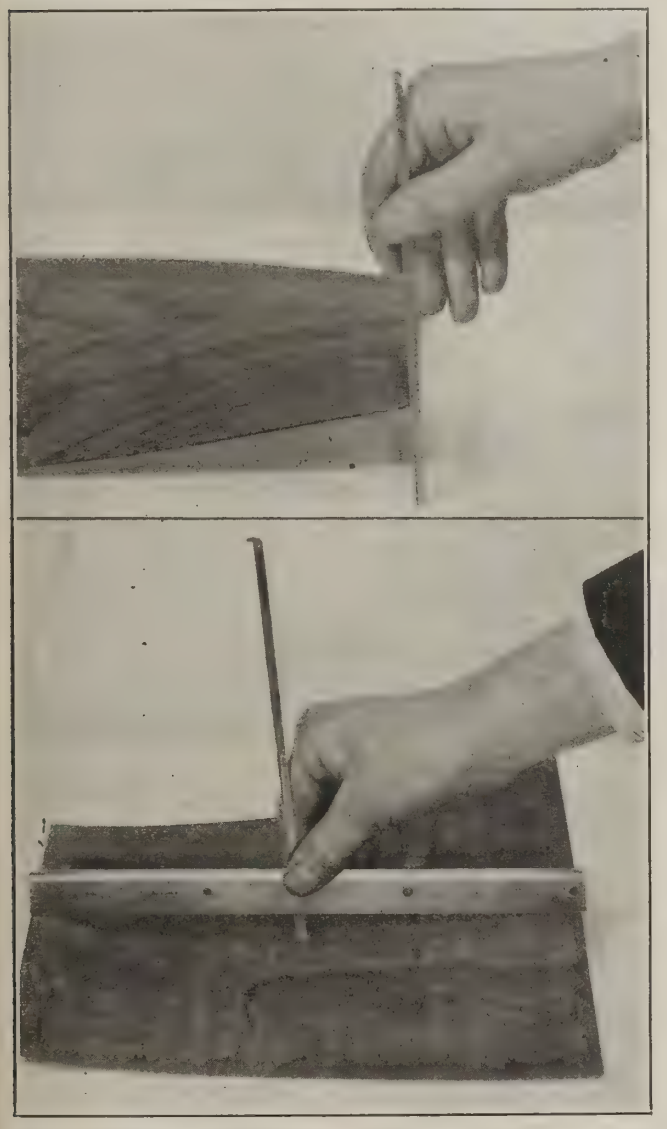

Fig. 2—Methods of measuring the cupping and twisting of plywood

In general, whenever a joint is made between two thick laminations which have their grain at right angles, there exists a tendency to weakness along the joint. This is also the case with plywood made up of heavy veneer, and is due at least in part to the greater shrinkage stresses that occur with thick plies. The use of fairly thin plies renders less likely the development of weakness along a joint.

Another consideration that is sometimes the controlling factor in deciding on the number of laminations, is that the extra glue required where many thin plies are used adds very appreciably to the weight. This point should always be considered. In case it is especially desirable that the plywood remain very flat, multi-ply construction is advisable. The reason that distortion is practically eliminated is that the shrinkage stresses are more nearly equalized.

Lastly, certain commercial reasons may affect the number of plies. Of these factors, the principal one is the extra labor entailed in the multi-ply type of panel. In certain instances, particularly where the total thickness of the plywood is small, the maximum number of plies is limited by the minimum thickness to which it is practicable to cut veneer. This varies with the hardness of the wood, the closeness and nature of its grain, and the method employed in cutting the veneer. For rotary cutting 1/48 in. is a usual minimum, and for slicing 1/64 in. Because of the difficulties in handling very thin veneer, the widths of such sheets are usually limited. Species of low density and open structure cannot as a rule be cut less than about 1/32 in. thick.

Ratio of Core to Total Thickness: As suggested before, the strengths of plywood in directions parallel and transverse to the grain of the face plies may to a large extent be modified by the ratio of the core to total thickness. The term core is here meant to include all the layers whose grain runs perpendicular to that of the faces. The purpose for which the plywood is intended largely determines this ratio of core to total thickness. For example, to obtain the same tensile strength in each direction, the core should be .5 the plywood thickness, while for equal strengths in bending this proportion should be .7. However, the presence of shrinkage stresses may introduce an uncertainty that upsets any calculations. A large proportion of core laminations is effective in reducing any tendency to distortion.

Low Density Species for Cores: The strength of a panel subjected to tensile stresses parallel to the grain of the faces is independent of the nature of the core. On the other hand, the modulus of rupture and the column strength may be very largely affected, owing to the fact that these properties are proportional to the moment of inertia of the cross-section of the panel. Of two cores, equal in weight but differing in density, the low density core will be the thicker, and hence will space the outer plies further apart. Experiments have shown that plywood in carrying an axial load acts like a long column whose capacity is a function of its slenderness ratio. From this it is apparent that any increase in the spacing of the face plies, secured by using a thick, low density core of basswood or poplar, will add appreciably to the column strength parallel to the grain of these plies. It should be carefully noted, however, that this increase in strength is due solely to the greater distance between the effective plies, and not to the character of the wood in the core.

In general, for large column strength the face plies should be thin, and of a strong wood like birch or maple, and be separated as far as possible. This same disposition of material will add to the resistance of the plywood to cupping and twisting.

In this connection the Forest Product Laboratory found from its tests that panels constructed of low density woods were less inclined to distort than those built up of species of high density. This slightly greater tendency to warp must be balanced against the better structural characteristics of a panel with strong face plies. It might also be added that tests have indicated no difference in the tendency to warp of wood cut by a slicer or rotary cutter, but sawn veneer will usually warp the least.

Total Thickness of Panel: Several thousands of tests on plywood of eight thicknesses, varying from 3/30 in. to ½ in. total, and including all the common species, give data on the effect of panel thickness upon the various physical properties of plywood. All the specimens in the tests were of rotary cut veneer, and each panel was three-ply, with all the plies of the same thickness. It was shown that the panel thickness has no effect on the unit, tensile strength. That portion of the material in which the grain was perpendicular to the direction of stress for the most part influenced the strength very slightly. The unit tensile strength parallel to the grain was 1½ to 2 times as great as that transverse to the grain.

Tests on the column bending modulus ($P/A + My/I$), a property analogous to the ordinary modulus of rupture for bending, brought out somewhat different results. When the load was applied perpendicular to the grain of the face plies this property was constant for all thicknesses. But with the load applied parallel to the grain of the face plies, a considerable uniform increase in the modulus occurred as the panel thickness was increased from 1/10 in. to ½ in. For all the common varieties of wood the total increment amounted to from 29 to 31 per cent of the value of the modulus when the thickness was 1/10 in. The ratio of the column bending modulus with the load applied parallel to the grain, to that when the load was perpendicular to the grain, varied from 4 to 5. The difference between the unit column loading (i. e., the direct compressive stress, P/A) in these two directions was even more marked. For this case the ratio between the column loads, parallel and perpendicular to the grain of the face plies, supported by two panels of the same length and sectional area, varied between 10 and 14, according to the species of wood. The variation, with the panel thickness, in the total load car-

ried was found to follow the law for slender columns and was proportional to the cube of the panel thickness, and the square of the column length.

Those tests made on panels constructed of two species of wood in combination demonstrated that the properties of plywood panels in the direction in which the load is applied are dependent entirely upon the character of the plies whose grain is parallel to this direction. For instance, irrespective of whether the core is of high or low density, provided its thickness is the same, the column bending modulus, the unit column loading, and the tensile strength of a panel are high if the face plies are of a strong, tough wood. And if the panel has a low density core and is subjected to a load transverse to the grain of the face plies the properties will all be as low as if the face plies were of no stronger wood than the core.

Resistance to splitting, as determined by the total work per inch thickness necessary to cause failure, increases to a certain extent as the panel thickness becomes greater. This property is of importance if screws or nails near the edge of plywood must be relied upon to hold it securely.

The cupping and twisting of a panel, of a thickness greater than ¼ in., is small and nearly constant. But with decreasing thickness the distortion grows large and variable.

Glued Joints and Splices

The Forest Products Laboratory has also conducted a number of tests on three-ply panels made up of 1/16 in. basswood and sugar maple veneer, to determine the most efficient types of splices and joints. Two series of tests were made. In the first series two kinds of joints were employed, the diagonal butt and the simple scarf. Some of the panels had a diagonal butt joint in both faces, and some in the core only. For this first series the scarf joints were all in the core. In the second series of experiments splices were made in one face ply only. They were of three types: the simple scarf, the diagonal scarf, and the saw-tooth butt joints. All tests were made in column bending, as shown in Fig. 3, the results being expressed in terms of the column-bending modulus. All the panels in the first series were 5 x 12 in.; those in the second set, 5 x 20 in. The panels were all tested with their long dimension parallel to the direction of the load.

Effect of Slope: The experiments on all-maple panels with a diagonal butt joint in each face indicated that the strength of such a joint increases progressively with its slope. For example, when the slope was 4 to 5 the efficiency of the joint was 20 per cent. This was brought up to 57 per cent. when the slope was 12 to 5. In the case of the all-basswood panels, the corresponding efficiencies for slopes of 4 to 5 and 12 to 5 were 41 per cent. and 100 per cent., respectively. In these two sets of tests the load was applied parallel to the grain of the face plies.

With the maple panels in which a diagonal butt joint was used in the core the efficiency, with a slope of 4 to 5, was 86 per cent., and it increased to 100 per cent. with a slope of 8 to 5. In the case of basswood panels, however, 100 per cent. efficiency was obtained with the minimum slope of 4 to 5.

A simple scarf joint in the core having a length of .7 in., which gives a slope of 1 to 11, had an efficiency of 85 per cent. for both maple and basswood panels. Had the length of the scarf been 1¼ or 1½ in. the joint would very probably have been 100 per cent. efficient. In all of these tests made on core splices the load was applied parallel to the grain of the core ply.

For the second series of tests the simple scarf joints were ¾, 1¼ and 2 in. long, corresponding to slopes of 1 to 12, 1 to 20, and 1 to 30. All the panels in this series had basswood cores. The ¾ in. simple scarf joint with maple faces was 59 per cent. efficient, the 1¼ in. point 93 per cent., and the 2 in. joint 100 per cent. The corresponding joints with basswood faces were 40, 100 and 100 per cent. efficient. When a diagonal scarf joint 1 in. long was used, the efficiency increased somewhat as the slope of the joint became greater, but in neither the maple nor the basswood panels did the diagonal scarf show any improvement over the simple scarf. Not until the slope was 12 to 5 did this joint give 100 per cent. efficiency.

The general results of tests on saw-tooth butt joints were the same for both maple and basswood panels. A joint in which the ratio of width of tooth at the base to length of tooth was 5 to 5 proved to be about 40 per cent. efficient, and as the ratio was decreased to 5 to 13 the efficiency rose to 80 per cent. In every test made on this type of joint failure

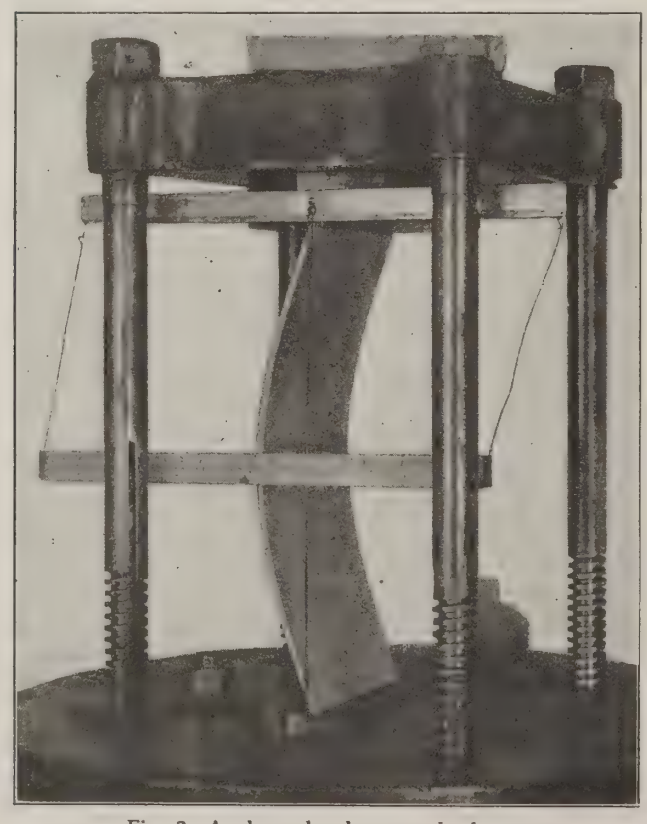

Fig. 3—A plywood column ready for test

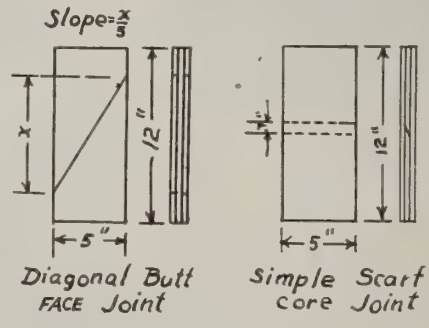

FIGURE 4

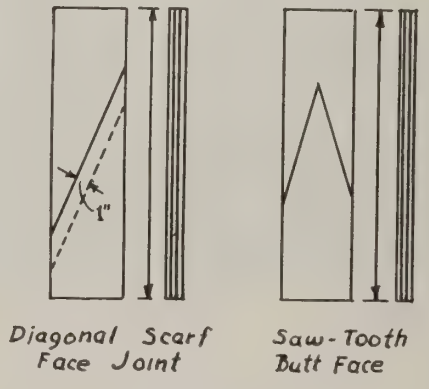

FIGURE 5

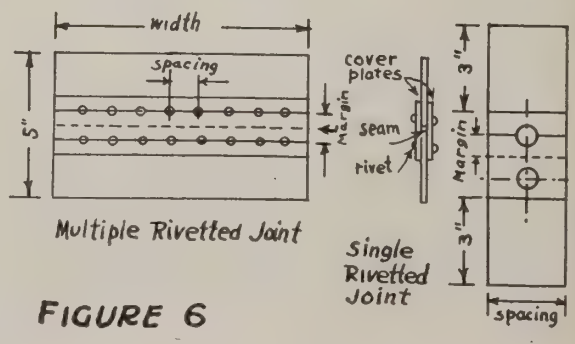

FIGURE 6

occurred in the glue. With both the saw-tooth and diagonal butt joints there was always a strong tendency for the point to separate from the core that was particularly noticeable in panels having maple faces.

In summarizing this discussion, it may be said that the saw-tooth joint is the least satisfactory of any of the types investigated, while the diagonal butt joint is not as good for most purposes as the simple scarf joint. The latter is superior to the diagonal scarf and can be made 100 per cent. efficient. The most effective length for a simple scarf joint in a 3/16 in. panel is 1½ in., which corresponds to a slope of 1 to 25. Figs. 4 and 5 illustrate the various kinds of joints tested.

Riveted Joints

Before it had been demonstrated that glued joints were much more satisfactory, except in special cases, than riveted, plywood joints extensive tests had been conducted on this type. But a brief discussion will be given of the results of this work. When the spacing of the rivets and the width of the margin are most efficient, the particular size of rivet used has no appreciable effect on the strength of the joint. Since, however, small rivets give their best values for a close spacing, a larger number of them is necessary. This causes much extra work when the smaller sizes are used. On the other hand, the largest rivets require only a third the number of holes and yet make as strong a joint. They are therefore generally to be recommended.

As a material for rivets, aluminum has the advantage over copper or steel due to its lightness, malleability, and the fact that it gives a tight fit when slightly upset. The tubular form of rivet is superior to the solid unless the size is very small.

The spacing of ⅝ in. rivets should be about 1¼ in. center to center, and the margin, or distance between the joint and the center line of the row of rivets, should be not less than 1½ in. A margin of 1¾ or 2 in. is recommended if the grain of the faces is perpendicular to the seam. For .15 in. copper rivets the best results were secured with ½ in. spacing and 1 in. margin. Fig. 6 illustrates the single and multiple-rivet types of joints tested.

All of these tests were made on joints with either a single rivet or a single row of rivets. For this reason no conclusions can be drawn or recommendations made relative to joints in which two or three rows of rivets are used. The kind of joint investigated was the butt type with two veneer cover plates. Veneer cover plates are probably best, though where the joint is exposed, the air resistance can be reduced by the use of sheet aluminum and by countersinking the holes so that the rivets will not protrude. The finished joint may be covered with cloth, glued on and varnished. When the grain of the outer plies is perpendicular to the seam the efficiency of the best riveted joints is about 30 per cent.; when the grain is parallel to the seam this value rises to about 50 per cent.

(To be continud.)

Functions and Organization of National Advisory Committee for Aeronautics

Washington, D. C.—At a meeting of the Executive Committee of the National Advisory Committee for Aeronautics, held on May 20, the following plan of organization was approved:

The Executive Committee shall have six sub-committees, to be known as standing committees on

(a) Aerodynamics,
(b) Power Plants for Aircraft,
(c) Materials for Aircraft,
(d) Personnel, Buildings, and Equipment,
(e) Publication and Intelligence,
(f) Governmental Relations.

These standing committees may, from time to time, appoint special sub-committees with the approval of the Executive Committee.

The functions and membership of the standing committees shall be as follows:

AERODYNAMICS:

Functions.—The functions and duties of this committee shall be:

1. To aid in determining the problems relating to the theoretical and experimental study of aerodynamics to be experimentally attacked by governmental and private agencies;

2. To endeavor to coordinate, by counsel and suggestion, the research and experimental work involved in the investigation of such problems;

3. To act as a medium for the interchange or information regarding aerodynamic investigations in progress or proposed;

4. The committee may direct and conduct research and experiment in aerodynamics in such laboratory or laboratories, either in whole or in part, as may be placed under its direction;

5. The committee shall meet from time to time on call of the Chairman, and report its actions and recommendations to the Executive Committee.

Organization.—Chairman, Dr. John F. Hayford; Vice-Chairman, Dr. Joseph S. Ames; Professor Charles F. Marvin; Colonel T. H. Bane, U. S. A.; Lieut. Col. V. E. Clark, U. S. A.; Dr. A. F. Bahm; Lieut. Commander J. C. Hunsaker, U. S. N.; Dr. L. J. Briggs; Mr. M. D. Hersey; Mr. E. P. Warner, Secretary.

POWER PLANTS FOR AIRCRAFT:

Functions.—The functions and duties of this committee shall be:

1. To aid in determining the problems relating to power plants for aircraft to be experimentally attacked by governmental and private agencies;

2. To endeavor to coordinate, by counsel and suggestion, the research and experimental work involved in the investigation of such problems;

3. To act as a medium for the interchange of information regarding aeronautic power plant investigations, in progress or proposed;

4. The committee may direct and conduct research and experiment on aeronautic power plant problems in such laboratory or laboratories, either in whole or in part, as may be placed under its direction;

5. The committee shall meet from time to time on call of the Chairman, and report its actions and recommendations to the Executive Committee.

Organization.—Dr. S. W. Stratton, Chairman; Mr. L. M. Griffith; Professor George W. Lewis; Major George E. A. Hallett, U. S. A.; Mr. J. G. Vincent; Mr. Harvey N. Davis; Dr. H. C. Dickinson, Acting Secretary; one member to be nominated by the Navy Department.

MATERIALS FOR AIRCRAFT:

Functions.—The functions and duties of this committee shall be:

1. To aid in determining the problems relating to materials for aircraft to be experimentally attacked by governmental and private agencies;

2. To endeavor to coordinate, by counsel and suggestion, the research and experimental work involved in the investigation of such problems;

3. To act as a medium for the interchange of information regarding investigations of materials for aircraft, in progress or proposed;

4. The committee may direct and conduct research and experiment on materials for aircraft in such laboratory or laboratories, either in whole or in part, as may be placed under its direction;

5. The committee shall meet from time to time on call of the Chairman, and report its actions and recommendations to the Executive Committee.

Organization.—Dr. S. W. Stratton, Chairman; Dr. G. K. Burgess, Vice-Chairman; Lieut. Col. H. C. K. Muhlenberg, U. S. A.; Lieut. Commander J. C. Hunsaker, U. S. N.; Mr. H. L. Whittemore, Acting Secretary.

PERSONNEL, BUILDINGS, AND EQUIPMENT:

Functions.—The functions and duties of this committee shall be:

1. To handle all matters relating to personnel, including the employment, promotion, discharge, and duties of all employees and others assigned to the committee for duty;

2. To consider questions referred to it and initiate projects concerning the erection or alteration of buildings and the equipment of buildings, offices, etc.;

3. To meet from time to time on call of the Chairman, and report its action and recommendations to the Executive Committee;

4. To supervise such construction and equipment work as may be authorized by the Executive Committee.

Organization.—Dr. Joseph S. Ames, Chairman; Dr. S. W. Stratton, Vice Chairman; Professor Charles F. Marvin; Mr. J. F. Victory, Secretary.

PUBLICATIONS AND INTELLIGENCE:

Functions.—The functions and duties of this committee shall be:

1. The collection, classification, and diffusion of useful knowledge on the subject of aeronautics, including the results of research and experimental work done in all parts of the world;

2. The encouragement of the study of the subject of aeronautics in institutions of learning;

3. Supervision of the Office of Aeronautical Intelligence;

4. Supervision of the foreign office in Paris;

5. The collection and preparation for publication of the annual report and its appendices.

Organization.—Dr. Joseph S. Ames, Chairman; Professor Charles F. Marvin, Vice-Chairman; Miss M. M. Muller, Secretary.

GOVERNMENTAL RELATIONS:

Functions.—The functions and duties of this committee shall be:

1. Relations of the committee with Executive Departments and other branches of the Government;

2. Governmental relations with civil agencies.

Organization.—Dr. Charles D. Walcott, Chairman; Dr. S. W. Stratton; Mr. J. F. Victory, Secretary.

Due to the reduced activities of the Air Service it has been necessary to report all class 3 officers who have been approved for the examinations. These are being surplused to the Air Service and available for assignment to other activities, but it is hoped that further Air Service legislation may permit the return of these men to duty with the Air Service.

THE GRAHAME-WHITE SPORTING AEROPLANE

THE feature which impresses one most on first seeing this Grahame-White model, to which the name of the "Bantam" has been given, is its extremely small size. The span of the G.W. "Bantam" is only 20 ft. and its overall length 16 ft. 6 ins., so that it may be housed in a very small shed. The smallness of the machine will, perhaps, be more evident from an examination of one of the accompanying illustrations than it would be possible to convey by any quotation of figures.

The G.W. "Bantam" is not a racing machine, the wing section having been designed with a view to fairly high lift rather than for high speed. In spite of this fact, however, the maximum speed is quite good—about 102 m.p.h. at low altitudes and 93 m.p.h. at 10,000 ft. As the engine fitted is of 80 h.p. (le Rhone), this is not a bad performance, especially as the climb appears to be very good. The landing speed is about 40 m.p.h.

As regards her handling in the air, she appears capable of practically all the evolutions performed by the higher-powered machines, although her lower power naturally does not allow of such steep climbs or prolonged "Zooms" as may be tackled with immunity in single-seaters designed for military purposes and fitted with engines of three or four times her power. The machine is very sensitive on the controls, both laterally and longitudinally. This is, presumably, due to her small moments of inertia around all three axes, and to the general compactness of the machine.

The 80 h.p. Grahame-White "Bantam"

The general specifications of the Grahame-White "Bantam" are as follows:

General Dimensions

Span, upper plane	20′
Span, lower plane	18′ 4″
Chord, upper plane	4′ 6″
Chord, lower plane	3′
Overall length	16′ 6″

Areas

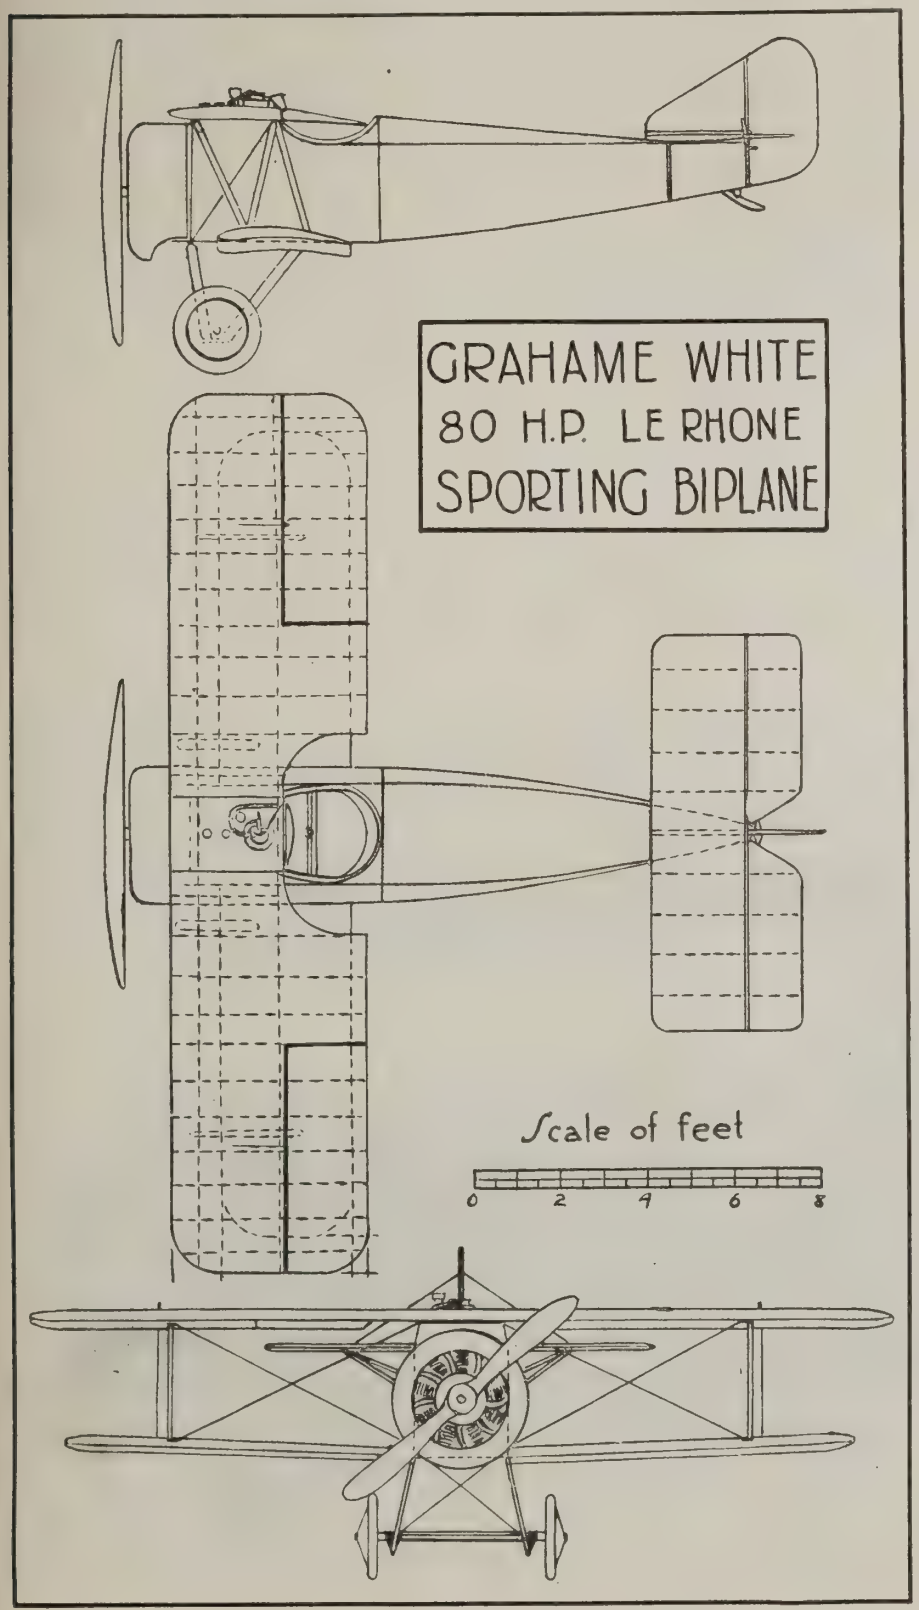
	Sq. ft.
Upper main plane	83
Lower main plane	47
Ailerons, each	8
Stabilizer	19
Elevators	10
Fin	3.75
Rudder	5.5

Weights

	Pounds.
Empty	640
Fully loaded	995
Weight per horsepower	12.45
Load per square foot	7.51
Disposable load (apart from fuel)	200

Performances

Speed at low altitude	102 M.P.H.
Speed at 10,000 feet	93 M.P.H.
Landing Speed	40 M.P.H.
Tank capacity, hours	2.3



Some constructional details of the Grahame-White sporting model.—1. The spar box and lug for attachment of interplane strut. 2. The wiring plate and socket for tubular compression strut of internal bracing. 2 is secured to 1 by two horizontal bolts. Fig. 3 is an external view of the attachment to the bottom front spar of the interplane struts. The controls are shown in Fig. 4, details of which are indicated in Fig. 5. Fig. 6 shows the fuselage clip. Details of the undercarriage are shown in Figs. 7 and 8.

Constructionally the G.W. sporting model shows many detail features that are of interest, some of which we have illustrated in the accompanying sketches. The object which the designer, M. E. Boudot, has kept in mind in getting out the details is simplicity and ease of manufacture. The construction of the wings follows more or less standard practice as regards the details. The spars, which are of I-section spruce, rest in mild steel boxes to which are attached the lugs for the interplane struts, and also the wiring plates and sockets for the compression tubes of the internal bracing system. In the accompanying set of sketches Fig. 1 shows one of the top plane front strut attachments. The spar box has riveted and brazed to it the lug for the interplane strut, and is extended inwards to form the wiring plate for the front lift cable. Two vertical bolts secure the box to the spar, while the wiring plate for the internal drift bracing is attached to the spar

and to the box by two horizontal bolts. (Fig. 2.) A somewhat unusual feature of the top plane is the position of the rear spar, which is a good deal farther forward than is the custom. This is done in order to make it clear the pilot where it crosses the fuselage.

The top plane runs straight across from tip to tip without any dihedral, and is attached to the top of the fuselage by a very strong box-like structure, covered in with the rear of the body and containing the main fuel tank. The rear face of this box serves as a support for the instrument board. The fuel service tank is enclosed in the center of the top plane.

The bottom plane is built in two halves, each attached to the ends of two short lengths of spars permanently fitted under the bottom of the fuselage. The front spar attachment is situated between the front and rear chassis struts, while the rear spar attachment coincides with and is part of the rear chassis strut fitting. The bottom plane spar fittings are of the same type as those of the top plane. Fig. 3 shows the bottom front spar fitting in external view. In principle it is the same as that shown in Fig 1, but the lug has accommodation for two interplane struts, the struts being arranged in this machine in the form of a letter N. The struts are elliptical section steel tubes. This same N formation is also found in the lift bracing, which consists of plain stranded cable. In addition to the usual two lift cables there is a third one running from the top of the rear interplane strut to the attachment of the bottom front spar to the fuselage. The obliquity of this third cable assists in relieving the internal drift bracing of some of its load. The landing cables run from the bases of the interplane struts to a single point at the top rear spar where this meets the top of the fuselage.

The fuselage is of the usual girder type, with longerons of rectangular section solid ash. The struts are vertical in the rear portion of the body, and the bracing here is of solid wire. In the front part, that is from the pilot's seat forward, the body struts are arranged as a series of triangles without any wire bracing. The bottom of the fuselage is flat, but the top is surmounted by a turtle back, and the sides are slightly rounded off aft and more markedly so in front, where they finally merge into the circular shape of the cowl. The sides are rounded off with longitudinal stringers, which are attached direct to the vertical body struts in the rear portion, while in front, where the curvature is more pronounced, they are secured to light three-ply formers. The covering of the body is fabric in the rear half and three-ply wood in front.

The controls are of a very neat type, and are illustrated in some of the accompanying sketches. The details of the universal joint of the control stick are somewhat unusual and form the subject of a sketch. On the dash in front of the pilot are mounted a very complete set of instruments, conveniently arranged. The engine plate is one of the lightest we have yet seen, weighing as it does only 12 lbs. It consists of the usual capping plate over the nose of the fuselage, made of 14 gauge steel and further lightened by circular holes, flanged to give greater rigidity. The rear engine-bearer is formed by a pyramid of channel section members bolted to the main engine plate and carrying at their other end—at the apex of the pyramid—the rear engine support. The engine—an 80 h.p. le Rhone—is overhung and is surrounded by an aluminum cowl. At present no "spinner" is fitted, but later it is intended to fit one over the hub of the airscrew. The latter has, we understand, been designed acording to data furnished by M. L. de Bazillac, who has devised a method which affords, by the simple use of a series of charts, the simultaneous solution of both aerodynamical and static propeller problems at a glance without any involved calculations, all such data as diameter, pitch angle, blade sections, intake velocity, etc., being read off directly on the charts. As the machine is so small, it has been desirable to fit a propeller of very small diameter so as to keep down the height of the undercarriage, and this fact formed a severe test of M. de Bazillac's method. However, the efficiency appears to be good in spite of the small diameter allowed, and the method appears to have been proved very satisfactory. Certainly for quickness it has much to recommend it.

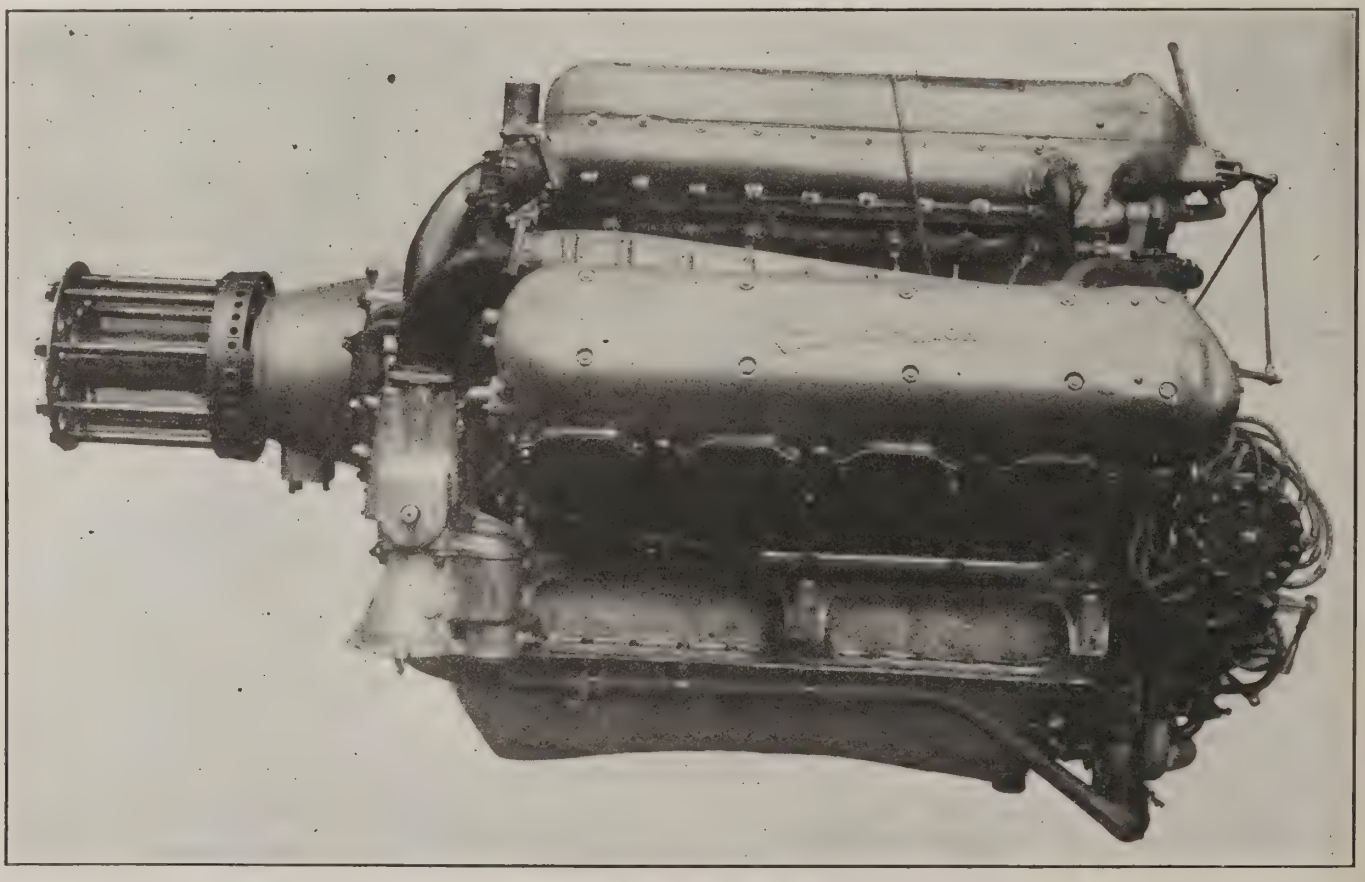
The undercarriage is a simple Vee type, with struts of stream-line section steel tubes. The manner of attaching these struts to the body is shown in one of the accompanying sketches. A very stout eyebolt passes through the bottom longerons

(*Continued on page 733*)

THE NAPIER "LION" 450 H. P. AERO ENGINE

AS will be seen from the illustrations the Lion aeromotor consists in the mass of three groups or "banks" of four cylinders each, mounted "broad-arrow" fashion at that angle to one another which, in the four-stroke cycle, has been found the most appropriate for ignition with but two magnetos, in the requisite range of advance and retard. In type it is just on the short-stroke side, the bore being 5½ ins., and the stroke 5⅛ ins.; the normal speed in r.p.m. being such as to sustain best the approved normal propeller speed, as effected by the reduction gearing, with a visible acceleration, so it is understood, above that normal, for the higher altitudes.

In the original serial issue, each group of four cylinders was water-jacketed, monoflux fashion, although each cylinder was formed then as now, as a unit machined from the solid steel forging. But now each cylinder is separately water-jacketed as well, the thin steel water-jackets being formed of sheet metal pressings, united in vertical welded seams back and front, and welded to cylinder flanges at the top and bottom of the water-spaces in a slightly downward tapering formation, the reason for which will be presently apparent. This construction not only eliminates gaskets and leak-rings, but also the adaptors and tapered wedge nuts for the sparking plug bosses of the former monoflux pattern; these bosses being now not only screwed into the cylinders, but welded in place. It will be noticed that on the induction side, and on either side of the boss-insertions—in each group—horizontal water-connections or spouts are welded into the top of the jackets, in flats pressed therein; and united with rubber hose-tubings and clips, so as to maintain a direct line water-inlet runway. On the exhaust side, at the bottom of the jackets, similar water-unions are likewise formed and united for a direct water outlet runway. But their lessened diameter being additional to the jacket taper, the object of keeping the cylinders warm and thus retaining greater thermal efficiency at all altitudes, is finally attained; this being one of the details of design obviously helpful towards the low consumption of the Lion motor.



To bring the cylinder units as close as possible, flats or straights are machined on the foot-flanges, which are held down to the crank-chamber by an adequate number of studs, as well as by three pairs of dog yokes on either side, lapping on the adjacent flanges.

The most original feature of the Lion mass-construction, however, is firstly that the cylinders are not, as in most other models, formed as open barrels, but with crowns, through which four holes are machined for the insertion of paired valve-seatings. Secondly, these crowns are machined flat so as to fit the underside of the monobloc aluminum casting of the so-called "cylinder head," which is actually (*a*) a stiffening block for the whole construction, (*b*) a water-receptacle for the cooling, by direct convection, of the thin cylinder-crowns, (*c*) a vehicle for the gas passage, in common manifold on either side, and as a mount for the induction; also (*d*) in its upper part, as a cradle for the mounting of the entire valve gear of each cylinder group, and as an oil-tight container when its cover is fitted.

The head-block has, of course, a separate water inlet and outlet, the connection in the former case varying according to whether the motor is to be used as a tractor or a pusher. For a tractor both cylinder jackets and head-block are water fed from a small two-way union casting aft, direct from the pump inlet connection, the outlets for both being in front; but for a pusher, the feed is first through the inlet-runway of the cylinders, then through a union-casting into the front of the head-block, and then out to the radiator through a pipe bolted to the flange at the rear-end of the head. In other words, the circulation is in parallel for the tractor and in series for the pusher.

For attachment of head-block to cylinders, as the third point of this construction, instead of struts or colonnettes, the valve seatings, which are shouldered heavily, are screwed from within the cylinders—as open nuts, so to say—into the base of the head-block; thus to form the inner ends of the gas passages, as unions, and at the same time the strongest of attachments, 16 in all. The method of screwing in is not material; but the simple ingenuity of the system will be as patent to all connoisseurs of motor-mechanics, as its effectiveness is—as and when fitted.

Those who have reviewed, much more those who have wrestled with the complications and encumbrances of induction manifolding will be the first to appreciate Mr. A. J. Rowledge's reduction of the whole proposition to a simple trough-shaped tapered aluminum casting, bolted up to the common induction passage for all four cylinders, the other longitudinal half of which is formed in the head-block. This practice, though previously

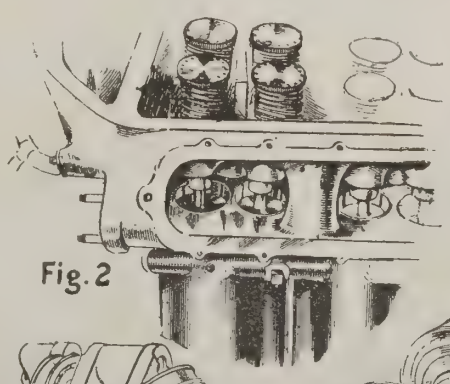
Sectional elevation of middle group of cylinders, showing lubrication system. The return or scavenger leads are in black

employed for the exhaust of smaller motors, is new for induction; and both theoretically and practically is better than a tabular formation integral with the head casting, as promoting the cleaner coring and accurate water-wall thickness essential in so powerful an aeromotor. Its taper is further purposeful, to increase the gas velocity and consequent full charging to the rear cylinders; not so well achieved even by the American endless hoop or shorehaul induction with its encumbrance of end-unions.

In this case the connection forward—for the right hand and vertical group, looking forward—is by two induction trunks, hot water jacketed from the head-blocks, with serial water connections to the jacketing of an N.S.2 duplex Claudel-Hobson carburetor; a similar induction-lead construction to a single N.S.1 carburetor of the same make, serving for the left-hand group. In all three, the water leads are returned to one or other of the water pump inlets.

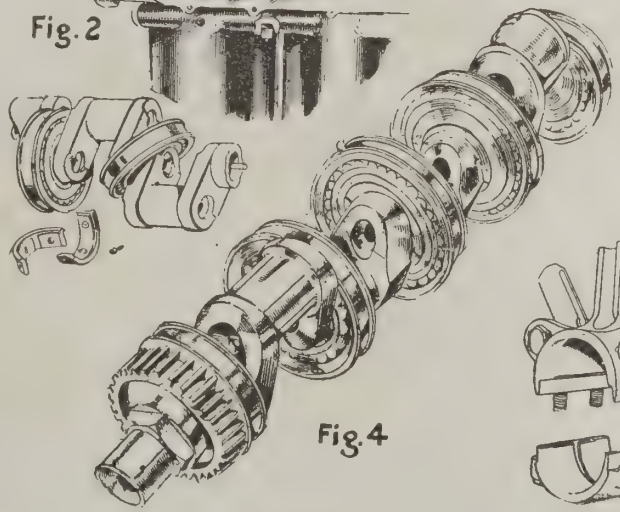
As to the carburetor control, suffice it to say that since forced induction for high altitudes is inappropriate, if not impossible in such a motor-design generally, the simpler—and only—alternative of petrol diminution is employed, and is effected by a certain method which more nearly equalizes the pressure in the mixing and float-chambers.

A further feature of the induction is the gas starter. Reference to the illustrations will show a connection set into the rear end of each induction passage cover. Each of these runs to the wall of a four-way distribution and equalizing cock. The inner drum of this device is so slotted, firstly, that it opens to each of the three induction connections in turn, while constantly open from the fourth connection; and secondly, so that, in the fourth or equalizing position of the control lever, it gives free communication between the three induction connections, while closing off the fourth connection from the charging apparatus.



This last is a pipe running to a two-way cock set in the inter-connections of a special vaporizer and air pump device, which is mounted independently of the motor, in any convenient position in the cockpit. In one position this cock closes off the vaporizer and gives direct communication between the air-pump and distributor, so that each group of cylinders can be scavenged out in turn, while in the other position it cuts off that communication, and turning the whole of the air from the pump through the vaporizer, likewise passes the resulting explosive mixture from the latter to the distributor; so that each group of cylinders in turn can be charged with mixture impelled by the pump, when the motor may be fired by the hand-starting magneto.

The air-pump is of the ordinary hand-operated double-acting type, with leather faced, spring-controlled inlet and outlet valves at each end; while the atomizer consists essentially of a carburetor-construction of the concentric float type, having a horizontal spray jet beneath its choke tube, to which the petrol supply is controlled by a quadrant-set needle-valve. Above the choke-tube is an inverted cone-shaped mixing chamber containing four umbrella-like gauze-screens of varying mesh, mounted one above another. In this way all the heavier constituents of the petrol are caught and drained back to the tank or a waste-pipe; and the whole atomizer, except the needle-valve control quadrant, is contained in a pot-like jacket, which may be heated with exhaust gases or hot water.



As for the exhaust, the single outlets from each cylinder are given any kind of manifold that suits the installation.

Coming now to the valve gear, this consists for each group, of two hollow camshafts, the cams of which act direct upon the adjustable tappet-heads of the valves; one shaft actuating the two inlets and the other the two exhausts of each cylinder. They are mounted in bronze bearings, in five cross webs in the cradle part of the head-block. One shaft is spur-gear driven off the other, in all three sets. Looking forward, for the right and left groups it is the inlet camshaft that is so driven, inwardly of the V, while in the vertical group is the exhaust camshaft.

The drive to the right and left groups is effected through bevel gearing from vertical drive-shafts—which for constructional assembly and dismounting purposes are in two parts, sleeve-united—mounted in long bronze sleeve-bearings at the top, around the union-sleeves, and at the bot-

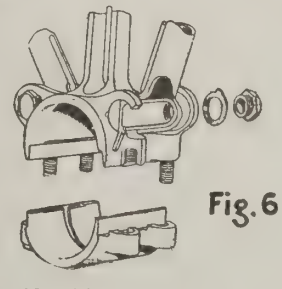


Fig. 2—Induction side of head-block. Fig. 3—Under side of head-block. Fig. 4—Crankshaft assembled with bearings. Fig. 5—Big end lubrication detail. Fig. 6—Big end construction detail

tom, above their driving bevels; each being enclosed within a tubular sleeve and lower encasement which constitutes a return for the excess valve-gear lubrication. Naturally, with the camshafts laid equidistant from the longitudinal axis of the head-block, the drive-shafts are off-set from the cylinder axes of each group to an appropriate angle. Also, the center one drives a tachometer, and the right-hand one a Remy distributor at half motor-speed; in both cases through skew-gearing located beneath the union-sleeves.

The valves, which are not interchangeable, the thickness of their stems differing, have wide hollow stems into which the tappet heads are screwed.

The distribution gearing, which is carried inside two castings bolted together, and to the back of the crank-chamber to form a detachable unit, is actually in two divisions. The first, that of the valve gear, consists of bevel gearing; the main driving bevel on the crankshaft engaging the drive-shaft bevels of the right and left hand groups, while a second bevel on the latter drive-shaft engages the drive-shaft bevel for the vertical group. This arrangement is manifestly necessary, as there would be no space for a third direct driven bevel among these smaller intermediate transmissions, in a progressive reduction to half speed, as between the first main drive bevel and the final driven bevels on the camshaft.

The second part of the distribution is from a one-piece double reversed bevel keyed upon a hollow extension-shaft; which is dog clutched into slots milled on the hollow crankshaft end and attached thereto by an open threaded ring enclosing both dogs and crankshaft end. The forward one of the two bevels engages another on the head of a spindle, which, immediately below this drive, carries a skew gear driving the two corresponding gears of the oil pumps, and is dog-clutched at the lower end to engage the water-pump spindle. The rearward driving bevel engages bevel pinions, right and left, to drive the two A.V.12 B.T.H. 12-cylinder magnetos—at one and a half-times the crankshaft speed—through vernier-adjusted, leaf-spring couplings from the intermediate pinion shafts to the magneto spindles.

So much for the essential mechanism and general arrangement of externals. The next interesting original feature of the Lion design—actually the most important component of the starting system—is the interconnected valve-relief control which enables the air-scouring and mixture-charging to be effected. This consists essentially of a set of T-shaped depressor-levers, four for each set of cylinders, which are anchored through lugs behind their shank-parts, to lugs beneath the camshaft bearings so that their T heads bear upon the tappet heads of the two forward valves of each cylinder; while the free feet of the shanks engage slots in a five-jointed spring-loaded pull-rod lying along the middle line of the valve-gear cradle at the bottom, with its rearward end brought through a bush in the cradle-end.

Now in the vertical group, this end of the rod carries a two-faced sheave-like collar, the inner face of which is engaged by the fork of a control-lever—anchored beneath to a bracket-arm on the head-block end—which, pulling out the rod, causes the T-pieces to depress the valves against their spring-pressure. At the same time the outer face of the collar engages the free arms of bell-cranks—also anchored to the head-block—the other arms of which are adjustably jointed to rods

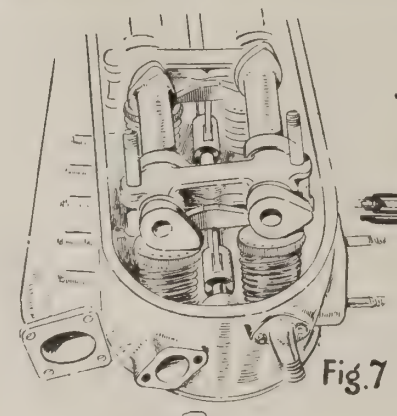

Fig. 7

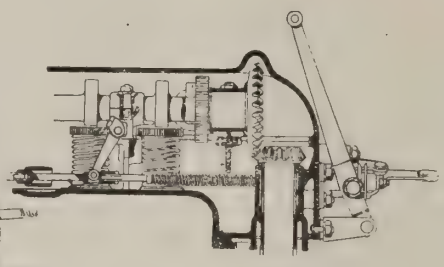

Fig. 8

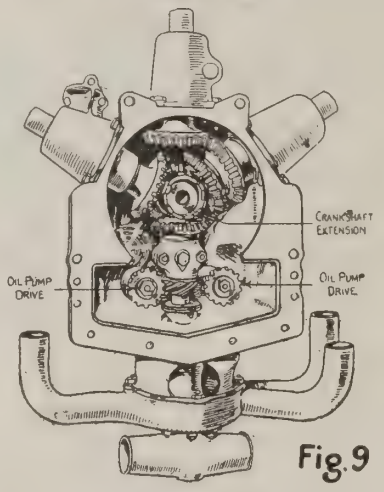

Fig. 9

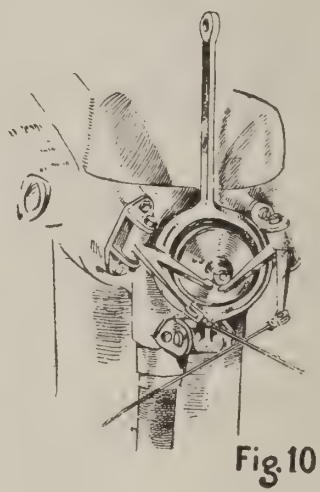

Fig. 10

connected to other bell-cranks, likewise anchored to the right and left head-block ends, and engaging the ends of similar pull-rods actuating the depressors in those valve-gear cradles.

Recollections of the original Panhard auto-starting system—on the same charge-pumping principle generally—of later adaptations of similar systems for high-powered motors; air-bottle practice and so forth, might convey the impression that the charging in this instance was up to some degree approaching normal pre-combusion pressure. For while it is obvious that the exhaust valves must be held open for the air-flushing, it is equally clear that while they remain open, no charging with mixture above atmospheric pressure can be effected, as any such charge would escape. Again, there is the equalizer, suggesting its own function, as apparently to establish an equal charge-*pressure* in all cylinders alike.

Both the impression and suggestion are all the more plausible that in a vertical or even a V-type, however mechanically balanced or roller-borne as to its crankshaft, some such arrangement, with charging at three atmospheres or so, would probably be essential.

Nevertheless—none of them happens to apply! The facts, on the contrary, in this case are, first, that apart from the complication of having—as the only practicable method in the circumstances—to *lift* the equalizer cut-off sleeve to some position in which it cut out all *four* connections, its equalizing function does not apply at all for the operation of charging, but solely—and essentially, in default of such a total cut-out—for subsequent running. In brief, it acts as a junction-point for a kind of perpetual triplicate connection constituted by the three pipings, precisely like the far end of a three-way "shorehaul" induction. Secondly, the grouping of the cylinders being, not even at a V, but at the greater fanwise angle, the connecting-rod thrust angle upon the shaft is so much greater, and bears as from so many more radii at a time, that what with the reciprocatory-weight mechanical balance and the roller-borne crankshaft suspension in further aid, the series of slight explosion efforts of charges ignited at merely atmospheric pressure have been found sufficient for starting. Consequently to effect a start, it is merely necessary to hold back the control lever as far as it will go. Then the cylinder groups, one after another, are flushed with air: next—by the operation of the two-way cock—they are charged with mixture impelled from the pump, and merely filled with it; the lever is let go and the valves closed; and finally, the equalizer level is set in the equalizing position for all subsequent running-induction, and the motor is ready to be started on the hand-operated magneto.

Internally, the chief features of the Lion motor are the crankshaft, with the special method of fitting roller bearings on the three intermediate journals; the connecting rod fitting; and the internal sump-scavenged lubrication for which all these parts and the valve-gear generally act as conduits; the only external piping being the two rearward scavenging connections from the sump to the pump, an upward connection to the valve-gear, and a third one forward to the propeller reduction gear.

The crankshaft has its pins and journals hollowed, and closed again by bolt-connected, valve-like plugs to form oil-cells, and its webs drilled diagonally to form a continuous or serial-feed oil con-

duit from cell to cell. The problem of getting roller bearings on the intermediate journals has been solved—albeit at the compromise of paring the web-faces somewhat heavily, above and below—in what is understood to be the R.A.F. fashion of slipping the races of outsized bearings over the webs, and packing up to them with halved steel bushes, shouldered on one side and stopped on the other with a little butt-screw in the foot of the adjacent web; one half of the bush being keyed to the journal to enable it to turn solid, and in a driving fit under the roller race. Theoretically the power-saving gain from the use of line-contact, all-but-frictionless bearings, is obviously enormous. Practically, owing to the diameter of the peripheral circle of the rollers, in this construction, the peripheral speed seems high.

The end-journals, of course, present no such difficulties, and owing to the reduction spur-gearing at the end, no thrust-races are needed; the roller-bearings being simply housed in the crank-chamber ends; their inner races threaded on the shaft; the inner faces butted by the webs; and their outer ones, held rearwardly by a keeper plate, and forward by the oil-thrower ring which is stud attached to the driving spur gear. The extremity of the crankshaft is mounted in a plain bearing housed in the metal of the reduction gear drum. Being hollow, it serves as the entry from beneath of the forward oil-pressure lead, as brought through the base-chamber from the other end; and is merely closed with a removable plate to facilitate the flushing of the whole circulatory system with kerosene after every 50 hours flying.

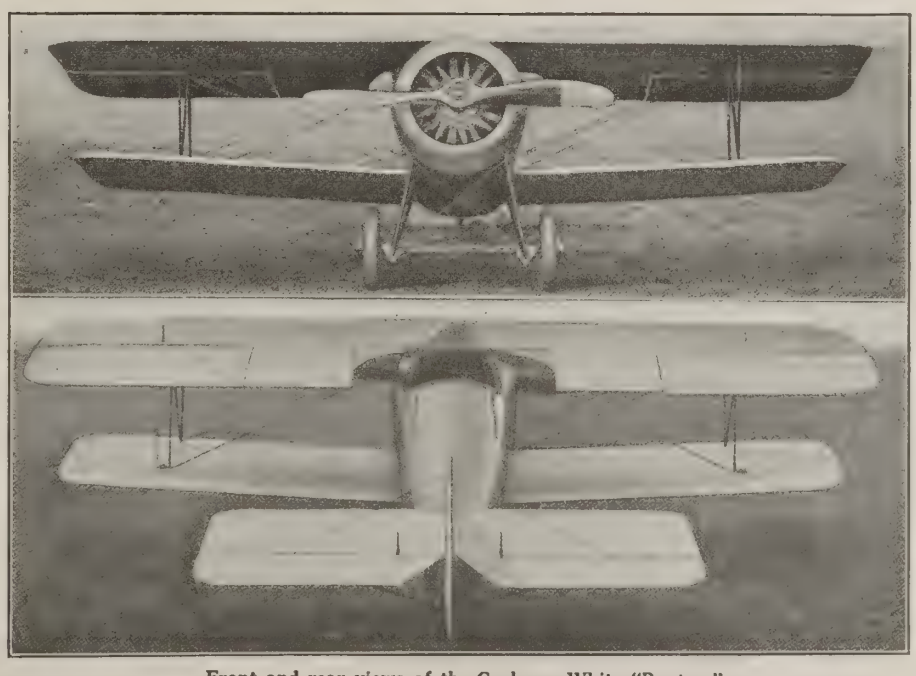
The pistons cast from a certain aluminum alloy, carry four rings on their very short trunks. These are chamfered and bored through beneath the two lower rings—which are scrapers—so as to return all lubricant in the slightest excess into the base-chamber. The gudgeon pins are hollow, and thus form the final oil-con- split-pinned set-screw in each case, they do not oscillate in their steel bushes. Thus the oil-feed is necessarily intermittent, but only slightly so, owing to the slight angularity of the rod-head oscillation. On the other hand, it is frequently argued that the oil consumption is rather greater with a gudgeon pin thus fixed than in one that oscillates with the rod-head.

The connecting rod group in each case consists of a central I-sectioned—all-but sectioned—master-rod, the big end of which houses a bronze bearing, white-metal-lined, and has its shoe—likewise lined—united in a scarf joint and attached by four-studs; while the side-rods are tubular, and anchored to lugs on the big-end by hollow pins, so locked by end nuts that they cannot move endwise, and so held by snugs that they cannot rotate. Thus these pins constitute oil-cells, intermediate to the crank-pin oil-cells on the one hand, and the gudgeon pins on the other. Their oil supply, although direct enough through the bearings, by way of bored leads, is, of course, rendered intermittent by the crank-pin rotation. But their upward feed, like that of the master rod, is effected by external oil-pipes, returned against and into the rod-heads, and thence goes intermittently, into the gudgeon-pins.

Mechanically, the great distinction between this and similar connecting-rod unions for V, Y or "broad-arrow" type motors, is that the pin-anchorage is neither upon nor near the shank of the master-rod—which is thus not subjected to "necking" stresses—but is solely upon the mass of the big-end itself, into which the lugs are stoutly rooted.

As to the lubrication generally of the Lion motor, thanks to the appropriation of the extraordinary working conditions by Mr. A. J. Rowledge, it is indeed a true circulatory system. It would be no duits to the cylinder walls. As they are pinned in the lugs with a taper ended exaggeration to say that the motor to this extent is designed round its lubrication. It is possible that it might be further simplified mechanically in a detail or two; albeit that proposition is not readily visible. And a further point to note is that the so-called oil-sump is not actually a sump at all, but, what is much better for "dry" lubrication, an oil-pan sunk towards the ends. Consequently in any case, whatever angle the motor may take, such oil as may be in the pan must go to the scavenger-pipe at one end or the other.

The oil pump itself consists of a body cast in two halves cored for the requisite oil passages, and bored to take six intermeshing gears arranged in pairs, above and below, on three spindles. Two of these spindles, as previously stated, are driven by helical gears from the vertical oil pump driving spindle. The two lower gears in the front part of the body draw respectively from the forward and rear end of the sump, and deliver to the upper gears, which they drive. These deliver to the rear end of the crankshaft, thence to the adjustable relief valve, and by external tubing, to the pressure gauge, and camshafts; while the pair in the rearward body—in tandem with the right-hand gears in the front one—draw from the tank and deliver to the front end of the crankshaft and the reduction-gear. The return-leads are, as already stated, down the valve-gear drive-shaft sleeves lubricating upon the distribution gear, and, by the outside tubing, into the reduction gear.



For the rest, the reduction gearing is mounted in roller bearings, housed in the drum-like upward extension of the crank-chamber; the propeller shaft, in addition, having double ball thrust bearings, housed inwardly of the outer roller bearing, so as to take all the thrust and allow the full benefit of the rolling-line contact of the latter to be obtained.

The final results of this design are that the entire motor, empty of lubricant, weighs only 1.79 lbs. per b.h.p. and only a fraction over 2½ lbs. per b.h.p. in running order with the water in the jackets; that the petrol consumption barely exceeds the b.h.p. hour half-pint, and the oil-consumption one gallon and a pint per hour for the whole.

THE GRAHAME-WHITE "BANTAM"

(*Continued from page* 729)

and through a heavy gauge wiring plate, the outer end of which serves as an anchorage for the lift cables, and the inner end of which is attached to a steel tube running horizontally across the bottom of the fuselage. Thus, when the machine is in the air this transverse tube is in tension owing to the pull of the lift cables, while during landing shocks it is put into compression owing to the angularity of the undercarriage front struts. The details will be clear from the sketch. At the bottom the two chassis struts meet on a short longitudinal tube to which the rubber cord is attached. At the point where the struts meet this tube internal reinforcement is provided to afford extra strength. There are two cross tubes in the undercarriage, one in front of the axle and one behind it. These are bolted to the chassis struts, the bolts passing through short lengths of tube welded into the struts, so that the compression caused by tightening up the bolts does not fall on the thin walls of the struts, but on the short lengths of tube welded into them transversely. The whole undercarriage is of the simplest type imaginable, and looks very sturdy for such a little light machine.

USE OF ULTRA VIOLET LIGHT FOR TESTING BALLOON FABRICS

By JUNIUS DAVID EDWARDS and IRWIN L. MOORE, Bureau of Standards

Introduction

IT is quite necessary to be able to determine in advance of construction of a balloon the probable resistance of the fabric to the deteriorating conditions of service. Extensive tests made at the Bureau of Standards and other places have shown that reliable indications as to the relative lasting qualities of different fabrics can be obtained by testing after exposure to the weather.

Deterioration from exposure to the weather is due, among other things, to the combined action of light, heat and moisture. These conditions are extremely variable, and as a result tests made during different periods of the year are not comparable. For that reason it is highly desirable to secure a reproducible, and, if possible, accelerated aging test. The effect of exposure to heat has been investigated by Edwards,* Tuttle and Walen, and it was shown that the relative deterioration of balloon fabrics produced by heating was not a reliable indication of their durability in service. Exposure to light from an ultra violet lamp has also been suggested and used for obtaining an accelerated aging test, on the assumption that the ultra violet radiation in sunlight was one of the chief factors in the deterioration of balloon fabrics.

Rosenhain, Barr and Booth† exposed balloon fabrics to ultra violet light from a mercury vapor arc in a quartz bulb. Two fabrics, both of which showed marked deterioration on exposure to the weather for 50 days, were exposed to the ultra violet light for 64 days. The action of the light produced no significant change in permeability in the case of one fabric, whereas there was marked deterioraton in the case of the other.

Victor Henri‡ has studied the effect of ultra violet light on rubber. Using a mercury vapor arc in a quartz tube placed 20 cm. from the exposing floor, he ran tests on samples of thin sheets of rubber 0.5 mm. thick. He found that unvulcanized rubber showed marked deterioration in 20 hours; the rubber became dark and shiny and cracked easily when stretched. The vulcanized sheets took 48 to 72 hours before showing any marked deterioration. He concluded that the addition of compounding agents generally increased the resistance of the rubber to oxidation. Litharge was especially marked in this effect. On the other hand, antimony sulphide greatly facilitated oxidation. Applying his conclusions to balloon fabrics, he recommends that (1) in their construction there should be no unvulcanized rubber, (2) that the cloth shall be dyed with lead chromate or aniline yellow so as to form a screen to ultra violet light, (3) that some yellow coloring matter be used in the rubber itself.

Bureau of Standards Tests

The tests made at the Bureau of Standards were primarily for the purpose of determining the value of exposure to ultra violet light for accelerated aging tests on balloon fabrics. The light source used was a mercury vapor arc, taking approximately 600 watts, in a quartz tube. This was mounted with a reflecting screen on a frame painted black and the whole placed in a galvanized iron container through which air was constantly drawn by a fan at the top. Two samples of fabric, 11 inches square, were tacked on a frame so shaped that the fabrics were on a 120° arc of a cylinder (radius = 11″) of which the lamp formed the axis. Radiation measurements were made from time to time to determine the total radiation from the lamp and the percentage of ultra violet radiation. The radiation measurements were made by W. W. Coblentz and M. B. Long, and a description of the performance and characteristics of the lamp will be given in another report.

Numerous tests of balloon fabrics exposed to the weather have shown that normal aging is usually accompanied by a slow increase in acetone extract and an initial decrease in permeability which is followed by a very large increase in permeability when the gas film becomes brittle and cracks. The deterioration of the fabric can thus be judged by a comparison of the permeability and acetone extract determined before and after exposure. The permeability was determined by the Bureau of Standards' method as described in Technologic Paper No. 113; the permeability is expressed in liters per square meter per 24 hours. The percentage acetone extract was determined by the method described in the third annual report of the Advisory Committee previously referred to. The results of a series of tests on balloon fabrics after exposure to ultra violet light are given in Table 1. The results of similar tests of the same fabrics before and after exposure to the weather for 30 and 60 days are given in Table 2.

A brief description of each fabric is given in the following tabulation:

No. 22151—Two-ply fabric, olive green rubber coating on outside.

No. 23987—Two-ply fabric, gray rubber coating on outside.

No. 10650—Two-ply fabric, gray rubber coating on outside.

No. 24580—Two-ply fabric, olive drab dyed fabric on outside.

No. 22151X—Same construction as 22151 but from different roll.

No. 27331—Single-ply fabric coated with fine para rubber and sulphur.

No. 27291—Single-ply fabric, same coating as 27331 except that lamp-black has been added to the compound.

TABLE 1

Effect of Exposure of Balloon Fabrics to Ultra-Violet Light

Fabric No.	Test		Permeability (25° C) and Per Cent Acetone Extract after Exposure							
		Time of Exposure in hrs.	Original	43	144	158	162		360	196
		Total Radiation in gm. cal. per sq. cm.		1015	2675	2410	1317		7410	1575
		Ultra-violet radiation in gm. cal. per sq. cm.		670	1712	1495	738		4650	898
		Moisture Condition		Wet	Dry	Wet	Wet	Dry	Wet	Dry
22151	Perm.....		15.4	13.4						
	% Ac. Ex..		2.2	3.4						
23987	Perm.....		11.4	14.6						
	% Ac. Ex..		1.7	2.6						
10650	Perm.....		17.5		12.5	11.1				
	% Ac. Ex..		1.6		3.6	4.8				
24580	Perm.....		9.4		8.0	4.9			320.	
	% Ac. Ex..		2.0		5.5	7.2			13.9	
22151	Perm.....		15.4				10.1	12.1	17,800.	
x	% Ac. Ex..		2.0				5.8	4.8	15.6	
27291	% Ac. Ex..		1.3							4.7
27331	% Ac. Ex..		1.9							16.6

NOTE—All samples were wrinkled before testing for permeability by being drawn ten times over a metal edge (angle 90°) under a constant tension of one pound per inch.

The values given in the column marked "total radiation" are for all wave lengths from 0 to 1.2μ. The values in the column marked "ultra-violet radiation" are for all wave lengths from 0 to 0.45μ.

For the proper interpretation of the data obtained in these tests it is necessary to consider the character of the radiation to which the fabrics were exposed. The figures given in the table for total radiation from the mercury arc are for all wave lengths from 0 to 1.2μ. The total radiation for all wave lengths (from 0 to infinity) is, however, about five times as great. This is due to the large amount of heat radiated from the hot quartz tube and electrode. The values for the range 0 to 1.2μ have been used for purposes of comparison because over 80 per cent. of the solar radiation is of wave lengths less than 1.2μ. The visible portion of the spectrum lies approximately between the wave lengths 0.38μ to 0.77μ.

Measurements on the mercury arc show that the radiation changes in character and intensity during the life of the lamp. At first as high as 70 per cent. of the total radiation was of wave lengths shorter than 0.45μ (ultra violet); this percentage decreased steadily with use until finally only about 50 per

27291	% Acetone Ex.	1.3	11.5	
27331	% Acetone Ex.	1.9	31.	

NOTE—"Solar Radiation" is expressed in gram calories per square centimeter of horizon al surface for wave lengths from 0 to 1.2W. These values were calculated from the daily observations of the Weather Bureau at Washington.

NOTE—All samples were wrinkled before testing for permeability by being drawn ten times over a metal edge (angle 90°) under a constant tension of one pound per inch.

cent. of the radiation was ultra violet. The intensity decreased at the same time until it was only about one-third of the original value.

For purposes of comparison there is given in Table 3 the approximate composition and intensity of the radiation from the mercury arc and the sun. The values for solar radiation are for average summer conditions in Washington and the values for the lamp are an average of the conditions under which the fabrics were exposed. The intensity and distribution of radiation from the two sources is shown by this table to be quite different. The rate of radiation of ultra violet light is about three times as great from the lamp as from the sun. Even this radiation is not of the same character as that from the mercury arc, as most of the ultra violet radiation from the sun is of wave lengths between 0.4μ and 0.3μ, while the ultra violet radiation from the mercury arc extends below 0.2μ.

A consideration of the data in tables 1 and 2 shows that exposure to the ultra violet light produces deterioration comparable qualitatively at least with that obtained by exposure to the weather. It was found, however, that the action of the ultra violet lamp was not nearly as rapid as had been hoped for. For example, fabric No. 22151 showed rapid deterioration in summer weather in less than two weeks, whereas under the ultra violet light there was no marked deterioration in 43 hours. For this reason it was necessary to extend the period of exposure in order to secure positive evidence of deterioration.

Further experiments showed that it required between 162 and 360 hours' exposure to secure complete deterioration of fabrics Nos. 22151 and 24580. Practically the same result was obtained after 30 days' weather exposure in the case of No. 22151, while the deterioration under the lamp in 360 hours was greater in the case of 24580 than in 60 days' exposure to the weather. Judging from service tests and weather exposure tests fabric No. 24580 is far superior to No. 22151 and yet the exposure to ultra violet light shows only a slight difference in their resisting qualities. Even when the amounts of ultra violet radiation were the same in both outdoor and mercury arc exposures the degrees of deterioration produced were very different. In the case of fabric No. 22151 the ultra violet radiation from the sun during 30 days' exposure to the weather was 700 calories; during 43 hours' exposure under the lamp the ultra violet radiation was 670 calories. Yet this fabric showed no significant deterioration in 43 hours under the lamp, but was practically destroyed by 30 days' outdoor exposure. Take another example: Fabric No. 10650 during 158 hours' exposure under the lamp did not show very great deterioration, but was ruined by 60 days' weather exposure. The ultra violet radiation in the first case was 1,495 calories and in the second case 1,300 colories.

Tests were made to determine, if possible, the influence of moisture on the rate of deterioration. In the tests marked "wet" the samples were sprayed with water twice daily. The "wet tests" show a somewhat more rapid action than those made with the fabric dry. That the diffierence between tests made under the two conditions is not greater is probably due to the fact that the normal humidity of the air in the room is sufficient to maintain an appreciable percentage of moisture in the "dry fabric."

The effect of temperature upon the deterioration is a factor the influence of which is hard to estimate. Fabrics exposed under the lamp were at a temperature of about 50° C. Fabric No. 22151 when exposed in bright sunshine in midsummer frequently reached this temperature. In general, however, the temperature of fabrics under outdoor exposure was lower than those under the lamp.

Conclusions

It seems evident from these few tests that the relative deterioration of different fabrics under ultra violet light is not strictly comparable with the deterioration experienced in service or in outdoor exposure. The radiation from the mercury arc lamp varies greatly in intensity and character and exposures made at different times are not strictly comparable; moreover, it is not practicable in most laboratories to measure the radiation from the lamps. The tests are thus far from being reproducible and are not particularly accelerated compared with summer exposure in Washington.

TABLE 3

Comparison of Solar Radiation with Radiation from Quartz Mercury Lamps

A. Comparison for all Wave Lengths 0 to ∞

Wave Lengths of Radiation in W	Solar Radiation at Washington		Mercury Arc Radiation	
	Gram Cal. per Sq. cm. per sec.	Percent of Total	Gram. Cal. per Sq. cm. per sec.	Percent of Total
0 to 0.45	0.0008	5	0.0026	12
0.45 to 1.2	0.0121	78	0.0017	8
1.2 to ∞	0.0026	17	0.0176	80
0 to ∞	0.0155	100	0.0219	100

B. Comparison for Wave Lengths less than 1.2 μ

0 to 0.45	0.0008	6	0.0026	60
0.45 to 1.2	0.0121	94	0.0017	40
0 to 1.2	0.0129	100	0.0043	100

The values for solar radiation were calculated from data given in the Smithsonian Physical Tables.

The values for the radiation from the mercury lamp are for a distance of 28 cm. from the quartz tube and are an average along its length.

EFFECT OF WRAPPING ON THE STRENGTH OF AEROPLANE STRUTS

THE practice of wrapping aeroplane struts or wing beams with canvas developed under the supposition that such wrapping increased the strength of the members at critical points, prevented sudden failures, and kept out moisture. Wrapping has been advocated especially for cross-grained material in order to make available for aeroplane construction stock which would otherwise be rejected.

Extensive tests have been made at the Forest Products Laboratory for the United States Air Service to determine the reinforcing value of such wrapping. These tests were made upon cross-grained struts of Sitka spruce and Douglas fir partly or entirely covered with Bakelized canvas or the standard cotton tape, and upon some of the same struts with the wrapping removed.

The conclusions reached from the tests were as follows:

The addition of Bakelized canvas to cross-grained struts increases the load somewhat but decreased the load per unit weight; it also increases the deflection and work to final failure and hence the shock-resisting capacity of the struts.

Wrapping cross-grained struts with cotton tape according to standard methods has no appreciable effect on their strength. It is doubtful if any other methods of wrapping, such as cording, would increase the strength properties very greatly. There is also the probability that any wrapping or covering will be loosened by weather changes.

It is believed that canvas, tape, or cord covering is of less value than the same volume of wood, and since such a covering is likely to be heavier than wood it is of still less value when compared with the same weight of wood.

The AIRCRAFT TRADE REVIEW

National Aeroplane Co. Doing Large Passenger-Carrying Business in Southwest

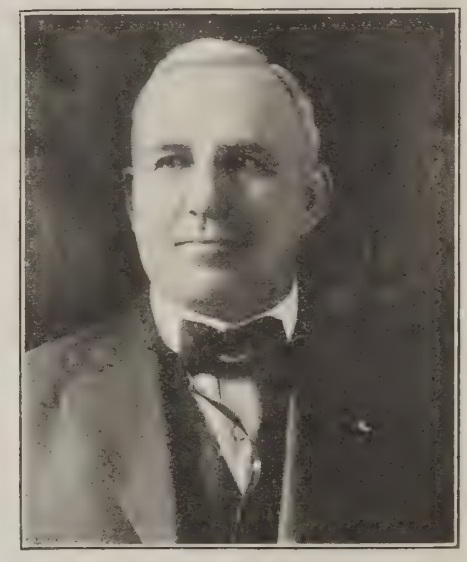
Fort Worth, Texas.—The National Aeroplane Co., a $5,000,000 corporation, successors to the Fort Worth Aerial Transportation Co., is operating an aerial passenger service between the following cities: Wichita Falls, Gainesville, Waco, Austin and San Antonio, Texas, and Ardmore, Oklahoma, where they have established sub-stations and landing fields.

The plans of the corporation provide for early extension of routes to as far as Kansas City and Denver, and the success of the project so far makes the directors of the corporation predict that they will be operating a hundred landing fields within a few months.

Chinese Purchase American-Built De Havilands

Toy Gon, former director of the Chinese Air Service and a member of the special commission appointed by the Government, has purchased a number of De Haviland aeroplanes equipped with Liberty motors. He has also negotiated with certain firms to supply commercial machines. Arrangements have been made for their immediate shipment to China.

Aircraft Factory Equipment and Tools On Sale by Air Service



Washington, D. C.—According to an announcement from the War Department, there is available for sale machine tools used in aircraft production valued at $11,000,000. It is expected to dispose of some of these in Europe.

No Radiator Trouble for NC Boats

Engine radiators played a very important role in the equipment of the NC seaplanes. Not only were the engines of all these planes perfectly cooled, but undoubtedly the radiator of the NC-3 helped to preserve the lives of officers and crew for it will be recalled that Commander Towers and his men subsisted for fifty hours upon chocolate and *fresh* water drawn from the radiators when they came down in the fog this side of the Azores, after flying over 1,000 miles. NC-4, which so splendidly accomplished the record-breaking flight, like her sister ships, did not experience even the semblance of trouble with the engine-cooling units.

During the war the Navy Department used many G & O Radiators. Therefore, when the transatlantic flight was first conceived, naval officers together with the G & O engineers began work on radiator specifications for the projected voyage. When approval of the specifications was finally secured orders were placed and only three days' time in which to complete radiators, from blueprints to finished product, for the most important flight in the world's history was allowed. The twelve radiators for the three planes were completed in every detail and finished on time. They were quickly followed by spares, but as none of the original radiators were replaced since the time they were installed at Rockaway, they were not needed.

The terrific strain which these boats underwent and the fact that the radiators successfully withstood the gruelling test is a high tribute to the radiator equipment.

W. W. Mountain, vice-president and general manager of the Curtiss Aeroplane & Motor Co.

Service Motor Truck Co. delivers parts from Wabash, Ind., to the Firestone plant at Akron. From left to right: Harold Brooks, H. S. Firestone, W. E. Duersten

Personal Pars

Capt. Henry E. Reece and Lieut. Nathan P. Oakes, using a Curtiss H, flew from Providence, R. I., to Washington, D. C., a distance of 448 miles in 300 minutes.

Flying a Handley Page on a flight from Elizabeth, N. J., to Ellington Field, carrying four officers and two soldiers, covered the 285 miles between Montgomery, Ala., to New Orleans, La., in 270 minutes.

Joseph Leopold has resigned his position as sales manager of the Jones-Motrola Co. in order to associate himself in a similar capacity with the Trego Motors Corporation of New Haven.

James A. Wright, W. Ruben Fisher, W. E. Jominy, Albert Harwith, William J. Kurth and L. F. Merritt, all of whom were engaged until recently in the Bureau of Aircraft production, have formed the Wright-Fisher Engineering Company at Detroit. The company will engaged in the designing of tools, dies, jigs, fixtures, special machinery, automatic machinery, heat treating equipment, etc.

Harry S. Finkenstadt, who enlisted in the aviation corps shortly after the United States' entry into the war, has recently been honorably discharged and returned to Detroit as western sales agent of the Carbon Steel Co., Pittsburgh.

L. R. Scafe, who was comptroller of the Dayton-Wright Airplane Co., Dayton, is secretary and treasurer of the American Finance Investment Co. of that city.

C. B. Kirkham, formerly chief engineer of the Curtiss Aeroplane and Motor Corporation, of Buffalo, and the Curtiss Engineering Company, of Garden City, L. I., has opened an office at 15 East Fortieth Street, New York. Mr. Kirkham is acting as consulting engineer for aeronautical companies, and is designing a line of aeroplanes and engines, which he has in mind for some time. He is also working on a plane for the Post Office Department. Mr. Kirkham is also directing the New York Office of the Deposited Metal Products, of Newark, N. J.

Manila Aero Club Demonstrates Aerial Mail to Director of Posts

Manila, P. I.—Flying under the auspices of the Manila Aero Club, Miss Ruth Law completed a series of mail-carrying flights before the Director of Posts and government officials. Plans for the establishment of a training field have been completed and arrangements for the purchase of planes are being made.

Official conferences have been held and the advantages of aerial mail for linking up the island demonstrated. Miss Law stated to the postal authorities that landing fields at intervals of perhaps ten miles will be required.

Aero Mail Service Between New York and Chicago Starts Next Week

It was announced by James B. Corridon, superintendent of aerial mail service of the Post Office Department, that the New York-Chicago aerial mail route will be placed in operation next week. At the same time the New York-Washington service will be transferred to Newark which will be the eastern terminus of all aerial mail routes.

The inauguration of the Chicago route from this field and the change of terminus for the Washington route, Mr. Corridon says, will mean the transfer of the Belmont Park station to the Newark terminal. The eight or nine aeroplanes now used on Long Island will be increased to fifteen, and all will be stationed in Newark, which will be the distributing point for supplies.

Mr. Corridon announced that the War Department has arranged to use the Newary station as a landing field. All aviators, whether in a private or commercial capacity, will be permitted to land at the field as long as it does not interfere with aerial mail operations.

Charles E. Bradley, Formerly of 271st Bombing Squadron in Aerial Mail Service

Charles E. Bradley, one of the newly appointed aerial mail pilots, was born at Sedan, Kansas, September 26, 1894. He graduated from Northwestern University, Chicago, Illinois, in 1916. His aeronautical ground school work was commenced in June, 1917, at the University of Illinois. He received his first instruction in flying at Wilbur Wright Field, Dayton, Ohio, in September, 1917, and later transferred to

Charles E. Bradley, former army aviator, now an aerial mail pilot

Ellington Field, Houston, Texas, to receive advanced training in flying. After completing a course in a bombing school he was assigned to duty with the 271st Bombing Squadron at Aberdeen Proving Grounds, Maryland.

He remained at this field, testing and experimenting with aerial bombs and bombing devices, until discharged on November 29, 1918.

He entered the Aerial Mail Service on March 30, 1919, and was assigned to the New York-Washington route, where he has been performing excellent service.

Room for Mail Clerk on Lawson Postplane

Washington, June 3.—Recent requests for bids for aeroplanes by the Air Mail Service resulted in eight bids, of which the lowest are from the Lawson Air Line Co., Milwaukee, which has designed a plane embodying mail car equipment, and allows for the employment of a mail clerk en route. The engines will be installed by the Government and it is expected that the Liberty engine will be used.

The aeroplane is of the biplane type, with the chassis built between the two wings, with engine space provided at each side. There is sufficient space so that the men can walk around the body, which is enclosed in glass. A rack has been designed in which the mail may be distributed during the flight, and a drop chute allows for the discharge of mail bags at principal cities without stops. A model of the plane has been ordered and will be demonstrated here when completed.

French and British Air Mail Services Carry 100 Tons of Mail During April

The following details regarding the working of the French aerial services have been given out by the French Bureau of Military Aeronautics:

On the semi-official Paris-Brussels line 34 trips have been accomplished, but more could easily have been carried out if necessary. On the Paris-Lille route, in 61 days between February 7 and April 10, 378 mail-bags weighing 78 tons were carried without accident. From April 1 to April 10 in 20 flights there was only one motor breakdown.

On the Paris-Bordeaux line, which is still in an experimental stage, from March 23 to April 29 there were 23 flying days, and 60 mail-bags, totalling 11½ tons, were transported. There were three smashes. The average time was four hours. The Paris-Strasbourg line, serving as a *liaison* with General Headquarters and the Government, between April 7 and April 13 made 15 voyages, carrying 128 bags, dispatches and newspapers, totalling six tons.

An interesting experiment in night mail carrying has recently been carried out by the R.A.F. authorities. A D.H. 10 machine with two 412 H.P. Liberty engines from No. 120 squadron left Hawkins Aerodrome, near Folkestone, at 10.30 P. M. and flying straight through without a stop reached Cologne at 1.30 A.M. The course taken covered about 300 miles, and as there was a fairly strong adverse wind the performance at an average speed of 100 m.p.h. was particularly good. This squadron, in conjunction with No. 110 squadron at Maisconelle, the transference point in France, has been responsible for the regular Folkestone-Cologne mail service, which has been flown since March 1. During the period March 1 to April 26 the squadron has carried no less than 1,634 bags of mails. In spite of exceptionally bad weather during a large portion of this period, particularly in March, there were only ten days upon which mails were not carried. The total number of mail flights made in these 47 days was 289.

NAVAL and MILITARY AERONAUTICS

Six Thousand From Air Service in Officer's Reserve Corps

Washington, D. C.—Appointees in Officers' Reserve Corps from the Air Service up to and including close of day, June 2, 1919, are as follows: Majors (flying) 21, (non-flying) 85; captains (flying) 79, (non-flying) 255; first lieutenants (flying) 401, (non-flying) 557; second lieutenants (flying) 3,670, (non-flying) 1,703; (balloon) 15. Totals: flying officers, 4,171; non-flying officers, 2,600; balloon officers, 15.

Colonel Frank Lahm Awarded D. S. M.

Washington, D. C.—The War Department authorizes publication of the following cabled communication from the Commander-in-Chief of the American Expeditionary Force:

"Pursuant to authority contained in cablegram A 2830, I have awarded the Distinguished Service Medal to the following American officers:

"Colonel Frank P. Lahm, Air Service, U. S. A. For exceptionally meritorious and distinguished services. A balloon pilot of marked ability and scientific attainments, he rendered valuable services to the American Expeditionary Forces by his untiring devotion to the innumerable problems which faced the Air Service during its organization in France. His broad experience in aeronautics played an important part in the formulation of policies of the Air Service and was reflected in its successes during the St. Mihiel offensive and subsequently in the operations of the Second Army."

Mitchel Field, Near New York, Purchased By War Department

The United States Government has practically completed arrangements for the purchase of Mitchel Flying Field at Hempstead, it is announced. The purchase price is understood to be about $450,000. The land was already under lease. Several million dollars had been expended for housing and equipment to make it the first field in the East. It is to be the centre of Government aviation in the East.

Lieutenant Emmons Received Distinguished Service Medal

Washington, D. C.—Lieut. Harold H. Emmons, in charge of aeroplane engine production, received the Distinguished Service Medal "for especially meritorious and conspicuous service as Chief of the Engine Production Department of the Air Service."

American Aviators Destroyed 755 Enemy Planes

Washington, D. C.—American fliers inflicted on the Germans double the loss they suffered in aeroplanes and balloons. An official report announced that 755 German planes and 71 balloons had been destroyed, while the American losses were 357 planes and 43 balloons, only victories which have been absolutely confirmed being credited to American fliers.

Board to Pick Air Defense Site

Selection of a site for a combined land and water coast defense station in the vicinity of San Francisco is to be made by a board appointed by the Secretary of War, which began its meetings at the headquarters of the Western Department at San Francisco recently.

The board, which will submit recommendations to the adjutant general, through the air service director, is made up as follows: Col. Alfred M. Hunter, C. A. C.; Col. Charles M. Potter, Engineer Corps; Col. H. H. Arnold, A. S. A.; Lieut. Col. C. T. King, Medical Corps; Major Albert D. Smith, A. S. A.

Air Service Officers in Cross-Country Flights

The War Department authorizes publication of the following from the Office of the Director of Air Service:

Lieut. Colonel Leonard H. Drennan, air service officer of the Northeastern Department, pilot, has reported the completion of an air flight between Boston and Hazelhurst Field, Long Island, reporting the distance covered 175 miles and the time as 83 minutes. Lieut. Colonel Drennan was accompanied by Lieut. Willis R. Taylor, as passenger. The flight was made in a De Haviland 4 plane at an elevation of 8,000 feet.

Colonel Davenport Johnson, commanding officer of this field, with Lieut. H. S. Ormsbee, pilot, in a De Haviland 4 made the flight from Chicago to Selfridge Field, Mt. Clemens, Mich., 250 miles, in 140 minutes, at an altitude of 5,000 feet. Between Michigan City and Chicago the aviators were over Lake Michigan a part of the way.

Lieuts. Andrew J. Hutterly, pilot, and William N. Cunningham have just completed an interesting flight over the mountains in Virginia and Pennsylvania as far west as Beaver Falls. The complete circuit of flight covered 1,000 miles and was made in 620 minutes flying time. The altitude varied from 1,000 to 8,000 feet, the latter on the last leg of the flight from Washington to Langley Field, Va. A Curtiss J.N. 4-H was used.

Air Service Gives Problems for Inventors to Solve

The Equipment Section of the Engineering Division have certain devices, appliances, etc., which they desire to develop. The following list is printed in order that inventors and designers may be familiar with a small number of our problems.

The particular problems referred to are:

Gasoline Tanks. A tank is desired which will withstand a salvo of fifteen shots fired at a range of thirty yards, the ammunition consisting of calibre 30, equally mixed, service, tracer, incendiary and armor-piercing bullets, fired through the tank at the most vulnerable angle without fire occurring, in ten consecutive tests on as many tanks. Naturally, the weight should be kept as low as possible and the maximum limit is about 75% more than usual standard tank weight. We will, of course, furnish all information to any one who desires it, regarding previous experiments.

Air Bag Floats, Landing Skids, etc. The object of these devices is to prevent machine from capsizing when landing in water, then remaining afloat. The British have made a fair success using these floats, but it would be desirable to have people start thinking about it.

Portable Hangars for Field Service. The present hangars, usually made of canvas, are unsatisfactory, and the usual drawbacks are either that they blow down in winds or that they leak or hold water in pools, or are too small. Any such hangar should be capable of housing at least four De Haviland planes with room enough left for working on them. They should incorporate the necessary wiring for electric lights and plugs for extension lamps.

Gasoline Supply Gauges. Much is to be desired with regard to a suitable gasoline supply gauge. The gauge should be responsive, serviceable, and accurate to the last one-half gallon. At present, the mounting for the gauge can be left on the tank, as it is thought that the mounting on the dash board will offer too many complications, unless done electrically.

Central Electric Power Plant. By this is meant the designing of a single generator and battery which will furnish the power required for the radio installation, the heating and lighting installation, the electric starter, the ignition, the motor driven camera; together with the necessary, perhaps, transformers to supply these various apparati with the electrical energy needed in its proportion and kind. This is to be engine driven in some way, and this will do away with the head resistance of the various wind driven generators now used. Of course this must, as it most surely will, manifest a saving in weight. The motors for which this is most desired are the Liberty 12 and the Hispano-Suiza 300. Two ideas are desired, viz.: the application to those engines already produced and simpler design to be incorporated in engines to be produced in the future.

Mobile Independent Cranking Device. This to be mounted on an auto truck. This device is to be an electrically driven cranker for planes not equipped with self-starters and is to be mounted on a motor truck. It is to be used at an aerodrome. Our idea of this device is one mounted on a truck that can be backed up to the front end of any aeroplane, then a flexible arm attached to the propeller. The electric energy is then to be brought into play which will crank the engine and cause the engine to begin firing. When the engine picks up, the device should be automatically thrown out of connection with the propeller.

Official Figures Issued on Air Service

On May 24, 1919, Air Service property consisting of 4,608 Curtiss OX-5 motors; 1,616 JN4-D Curtiss type planes, without motors; 1,100 Standard J-1 planes, without motors; with accessories and equipment now with the planes and motors, were sold to the Curtiss Aeroplane & Motor Corporation for $2,720,000.

It is estimated that the planes and engines, without the accessories and other equipment, were originally valued at approximately $22,500,000. During the summer of 1918 the Air Service discontinued the use of the SJ-1 plane; the JN4-D was recently declared "obsolescent."

Planes and Engines Condemned to April 30.

From the beginning of the war to April 30, there were condemned 1,105 planes and 853 engines of all types. The distribution by types is shown in the following table. Figures do not include Navy models and machines discarded shortly after the beginning of the war.

Primary Training	
Planes	861
Engines	713
Advanced Training	
Planes	211
Engines	129
Service	
Planes	33
Engines	11

Active, Obsolescent, and Obsolete Planes and Engines on Hand May 5.

In the following table is shown the status of service and training planes and engines in the U. S.

Orders issued by the Air Service in February classify aeroplanes as "Active," "Obsolescent," and "Obsolete." "Obsolescent" planes and engines are to be used until the supply is exhausted, but no extensive repairs are to be made or additional spares manufactured.

	New	Used, but in flying condition	Out of comm.	Total	Per cent — New	Per cent — Used, in comm.	Per cent — Out of comm.
ACTIVE							
Service engines	10,081	288	225	10,594	95	3	2
Service planes	2,127	167	163	2,457	86	7	7
Training engines	2,007	608	122	2,737	73	22	5
Training planes	773	980	488	2,241	34	44	22
OBSOLESCENT							
Training engines	4,480	3,942	2,214	10,636	42	37	21
Training planes	539	1,804	612	2,955	18	61	21
OBSOLETE							
Engines	1,419	158	963	2,540	56	6	38
Planes	1,026	65	940	2,031	51	3	46

34 Per cent of Aviation Engines Received in A.E.F. Were American Built

According to reports received from the Chief of Air Service, A. E. F., the total number of engines received up to November 30, 1918, was 10,464. Of this number 4,153 were Liberty 12's.

The number and per cent received from American and European sources follow:

	Number	Per cent of total
European	6,944	66
American	3,520	34
Total	10,464	

Service Planes Dispatched to American Forces in Zone of Advance

The total number of aeroplanes dispatched to the American Forces in the Zone of Advance to November 11, 1918, was 2,698. Of this number the British and French supplied 75 per cent.

Following is the number sent to the Zone of Advance and the per cent of total supplied from French, American and British sources:

	Number	Per cent of total
French	1,825	67
American	667	25
British	206	8
Total	2,698	
Total British and French	2,031	75

Special Orders Nos. 130-134, Inclusive

Capt. Charles S. Shotwell is appointed an acting quartermaster for the purpose of issuing bills of lading for the Material Disposals Section of the Bureau of Aircraft Production; vice Capt. Robert G. Woodcock, is hereby relieved.

The following named officers will proceed to Park Field, Millington, Tenn.: Second Lieuts. James D. Stewart, Manuel A. DeBettencourt, John R. Newell.

Capt. Everett J. Lee will proceed to Fairfield, Ohio, and report to Wilbur Wright Air Service Depot.

The following-named officers will proceed from Naval Air Service station, Pensacola, Fla., to Washington, D. C., on temporary duty not to exceed five days; thence to Hampton, Va., and report in person to the commanding officer Langley Field for duty: First Lieut. LeWallace W. Taylor, Second Lieuts. Theodore E. Faulk, Robert H. Finley.

The appointment of Second Lieut. Emmanuel Franklin, for the period of the existing emergency, to the grade of first lieutenant, with rank from June 6, 1919, is announced.

Second Lieut. Robert B. Howard, will proceed to Hazelhurst Field, Mineola, Long Island, N. Y., thence to Fort Hancock, N. J., thence to Little Silver, N. J., on temporary duty; thence to Hazelhurst Field, Mineola, Long Island, N. Y.

Second Lieut. William A. Gardner, will proceed to Kelly Field, San Antonio, Texas, for duty.

Maj. Robert Coker, will proceed to Washington, D. C., and report in person to the Director of Air Service.

Second Lieut. Ernest S. Hansberger will proceed to Washington, D. C., and report to the Director of Air Service.

Second Lieut. John F. Cullinan is detailed for duty with the Medical Department, and will proceed to Fort McHenry, Md., and report to the commanding officer, U. S. A. General Hospital No. 2.

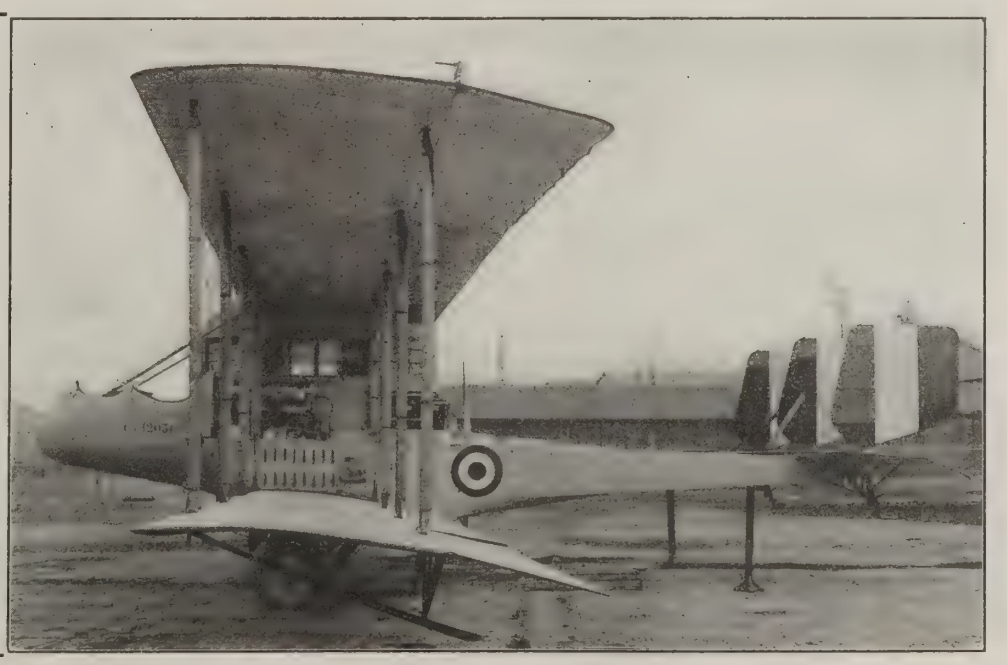
First Lieut. Ector O. Munn, is relieved from his present duty as assistant to the military attaché, Archangel, Russia, and will repair to Washington, and report to the Director of Military Intelligence for temporary duty, and upon the completion of this duty he will report to the Director of Air Service for duty.

First Lieut. Ralph E. Jones, will proceed to Aberdeen, Md., and report to the commanding officer Aberdeen Proving Grounds.

Second Lieut. Gladstone Rowe will proceed, accompanied by the necessary attendants, to Biltmore, N. C., and report to commanding officer, U. S. A. General Hospital No. 12 for further treatment.

The following-named officers will proceed to Langley Field, Hampton, Va.

Capt. Russell E. Collins, First Lieuts. Byron T. Burt, and Don R. Cameron.



Second Lieut. Daniel F. Duke will proceed to Rockwell Field, San Diego, Cal.

Second Lieut. John T. Belting is detailed for duty under the direction of the Director of Purchase, Storage and Traffic, and will proceed to Hoboken, N. J., and report to port of embarkation for assignment.

Second Lieut. Jack Greer will proceed to Chanute Field, Rantoul, Ill.

Capt. Horace Green will report to the Director

(*Continued on page 746*)

The Caproni "600" Biplane which carries 11 people; 3 pilots outside and 8 passengers inside. Wings have a span of 82 feet and a surface of 1,300 sq. ft. It is equipped with 3 Issotta-Fraschini engines, each developing 260 H.P. and connected to nine foot propellers. Speed 95 M.P.H. Weight about 5½ tons

FOREIGN NEWS

Allied Seaplanes Attack Bolsheviki

Klem, Northern Russia—Allied seaplanes attacked four Bolshevist craft on Lake Onega, south of here, on June 8. The bombs dropped did not hit the boat, but the machine guns carried by the aircraft raked their decks and silenced the anti-craft guns mounted there.

The Bolshevist flotilla fled and was pursued for a great distance. One allied plane returned to its base, reloaded bombs, and rejoined thet others in the pursuit. After the engagement all the allied machines returned.

Adjutant Casale Again Breaks World's Altitude Record

Paris.—Adjutant Casale, a French aviator has again broken the world's altitude record by ascending to a height of 31,168 feet. His previous mark, 31,012 feet was attained on May 28.

Aerial Derby Around London On June 21

London.—The aerial derby, after five years of war has been revived and will take place on June 21.

The race is to start and finish at the Hendon Aerodrome, and all London will have the opportunity of witnessing the spectacle of twenty to thirty high-speed aeroplanes racing around the suburbs of the metropolis and will be able to realize the remarkable progress made in flying machines since the race was first held in 1912, when T. Sopwith was the winner in a 70 H.P. Bleriot monoplane, his average speed being fifty-nine miles an hour.

In 1913 Gustav Hamel in an 80 H.P. Morane monoplane won at a speed of seventy-six miles an hour, and the winner of the 1914 contest was W. L. Brock, an American airman, in an 80 H.P. Morane monoplane, his speed being seventy-two miles an hour.

It is expected that the speed of the winner of this year's contest will exceed 150 miles an hour. The three entries already announced include an American pilot, Clifford B. Brodger, who will fly a B.A.T. scout, with a ABC engine.

King Albert Uses Aerial Transport Between European Capitals

London, Eng.—King Albert of Belgium is using the aeroplane almost exclusively in the travels between the European capitals. On May 15 he arrived at Hawkinge Aerodrome,, near Folkestone from Brussels. On the following day he flew from Folkestone to Gosport in a DH-9 machine, from whence he continued his flight in a F. 2A flying boat to Dartmouth in order to visit his son at the Royal Naval College. The return to Dover was made a few days later, from whence he returned to Brussels on one of the Folkestone-Cologne aerial mail service planes.

F. A. I. Excludes Germans

Paris.—At the first meeting of the Federation Aeronautique Internationale since the opening of the war was held at Paris at the Aero Club de France with representatives of France, Great Britain, Italy, Belgium, Norway, Holland, Sweden, Switzerland and the United States were represented. It was unanimously resolved that Germany, Austria and Hungary should be excluded from the Federation as long as they are not admitted to the League of Nations.

F-5 Seaplane and Handley Page Make Endurance Flights

London.—A stock F-5 seaplane fitted with two 350 horsepower Eagle VIII Rolls-Royce motors made an endurance flight of 14½ hours. The course followed was a coastel one, passing Margate, Eastbourne, Bognor, Brighton, Folkestone, Ramsgate, Sheerness, Cromer, Southwold, Lowestoft and back to Felixstowe, with which radio communication was maintained throughout the entire flight.

Another very satisfactory endurance flight was carried out recently from a Royal Air Force aerodrome in Norfolk by a four-engined (Rolls-Royce) V/1500 Handley Page service machine. Carrying a crew of five officers and three other ranks, the machine left the aerodrome at a few minutes before eight in the morning and did not land again until twenty minutes to eight at night, completing 11 hours, 33 minutes in flight.

The total distance flown over the ground was 836 miles, corresponding to a mean speed of 72.8 miles per hour, with a load of 24,890 lbs. all on.

In the course of the flight, Birmingham, Southport, Manchester, Lincoln, London, Felixstowe, Yarmouth, and Hunstanton were visited.

1,100 Miles Over Desert in One Day

Lieut.-Colonel Wilson, of the British Staff in Mesopotamia, has made a new record in flying from Mosul to England in a week. He was mounted on a D. H. 9A machine, and crossed the desert from Mosul to Cairo in one day, making three stops on the trip of 1,100 miles.

Commercial Aeronautics in Western Canada

Edmonton, May 17.—Aviation as a commercial enterprise will be tried out in Edmonton this summer, according to Court May, managing director of May Aeroplanes, Limited, a company which was incorporated recently with a capital of $20,000. The company will commence operations this summer.

Aero Club of Calgary Presented With Aeroplane

Charles W. Diffin, who is in Canada on business and who was chairman of the International Aircraft Standards Board, announced recently that he was prepared to make a sporting offer to the Aero Club of Calgary which, if accepted, would result in three or four machines being seen in the air here within six weeks. The planes are of the Curtiss JN-4 type, and are capable of attaining a speed of 75 miles an hour.

Fonck Flies Up 30,000 Feet

Issy les Moulineaux, France, June 4.—Capt. Rene Fonck, the famous French ace, attempted this morning to break the altitude record in an aeroplane of 31,000 feet made by Adjt. Casale May 28. The aviator rapidly ascended until he had attained a height of 30,000 feet. Here, however, his motor froze and he was forced to make a thrilling volplane with his engine stopped.

Portuguese Government Offers $30,000 Prize for Portugal-Brazil Flight

Lisbon, June 6. (Associated Press.)—The Portuguese Government today issued a decree establishing a prize of 30 contos (at normal exchange approximately $32,400) for the Portuguese or Brazilian aviator who flies from Portugual to Brazil.

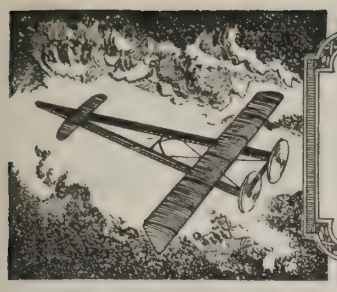
The Minister of Marine, in discussing the offer of a prize, said that Portugal had been stimulated by the example of the United States and intends to establish a commercial aviation route between Portugal and Brazil. The route would be from Lisbon, Madeira, the Canary Islands, Fernando Noronlia, and Pernambuco, a distance of 5,400 miles.

Fiat Co. Building Biplane for Trans-Atlantic Flight

Announcement is made by the Fiat Company of Turin, Italy, that it is preparing a machine for a flight across the Atlantic without the aid of patrolling seamships. The designers claim that they can make this flight of practically 2,000 miles in fourteen hours.

The machine now being built for the flight across the Atlantic is a large biplane, the fuselage of which is an all metal construction divided into water-tight compartments and used to carry 660 gallons of fuel. In case of a forced descent on the water this fuselage can be instantly emptied of its contents and will form a float capable of supporting the pilot and observer for a considerable length of time.

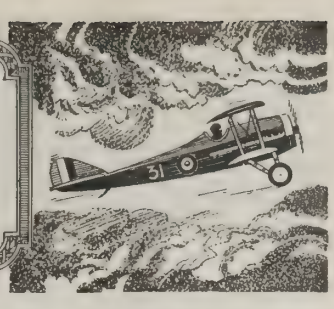
The Fiat biplane will be fitted with a single twelve cylinder engine of 700 horse-power, officially known as Type A-14.



Engineer Rosatelli, who is responsible for the design of the Fiat transatlantic machine, has tackled the problem on entirely original lines. He is of the opinion that success can only be obtained by a combination of high speed and high load carrying capacity. To accomplish the trip from the New to the Old World in the time limit imposed an average speed of 145 miles an hour must be maintained. This exceptionally high speed can be attained even with the large amount of fuel necessary for such a long journey.

By reducing the time limit in this way two possible sources of failure, namely changes in the weather and possible stoppage of the engine, will be considerably reduced.

Special study has been devoted to the problem of plotting out position while crossing the Atlantic and while flying at a speed of 150 miles an hour. Such satisfactory results have been obtained in this connection that the Fiat engineers and the pilot of the aeroplane are determined to start without any assistance from ships placed along the line of flight.



Fiat-motored S. I. A. bombing and reconnaissance machine. The S. I. A. Company is a subsidiary of the Fiat Company

Contest for Aerial Age Prizes

Returns are coming in for the AERIAL AGE *contest*, and from the results new records are going to be established. The distance contests returns are now around the 1,000-foot mark and with prospects that they will be much higher when the final roll is called. Such clubs as the Aero Science, the Illinois Model Aero Club, and the Pacific Coast Model Aero Club have not yet sent in their reports. It is expected when they are received new world records will be established.

Most clubs are holding elimination contests to decide who will be in the final contests, which is good practice where there are a good many members. They will no doubt hold their final contest the last week in June.

The competition for construction is also well contested and the photographs received are worthy of exhibition without considering the models. From what we have received so far it looks as though others who wish to be considered as "up with the leaders" will have to work like beavers, for the workmanship displayed is far above the ordinary.

Whether you are lucky enough to win this prize or not, you will be well repaid for your work, as your model will have a certain value in itself. In many cases it can be used as a show window attraction and rented to different shopkeepers. We would like to receive as many returns for the flying contests and photos for the construction contest as possible so as to prevent all the returns coming in at the last moment.

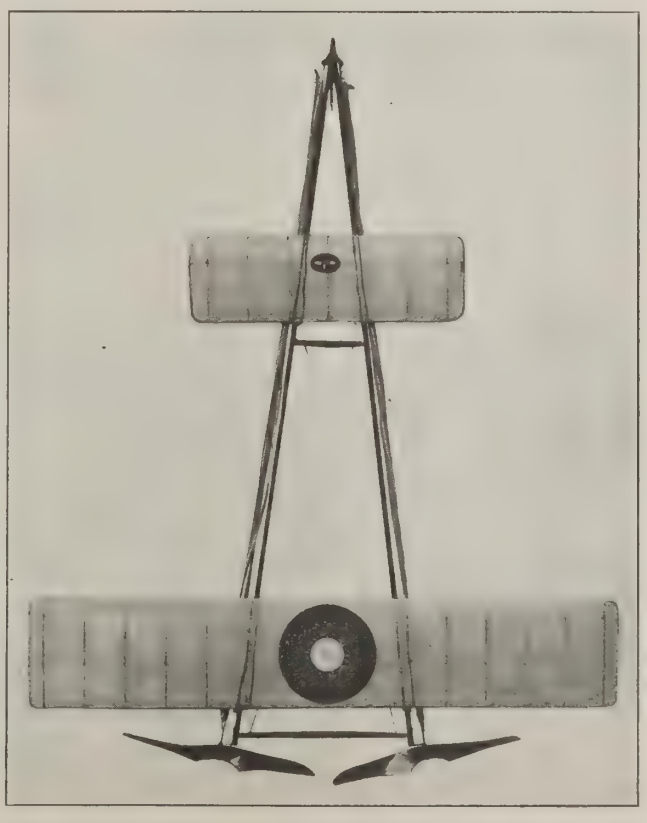
Remember that all returns and records must be signed and witnessed by at least three influential citizens of your town, and the construction entry must be accompanied by a photograph and a full description of the model.

A New Flying Model on the Market

In England before the war many firms manufactured and sold models to the model fliers, who entered and flew them in contests for prizes. These models were always made from a copy of some record holder or were manufactured by some champion aeromodelist and the purchasers would feel that they had made a good bargain.

It seems that America is following in the footsteps of our cousins the English, as one of our latest formed companies, "The Flying Model Airplane Corporation," has placed on sale a full line of real racing flying models of championship form and workmanship, and the large-size racing model is shown in the accompanying photograph.

These models were designed and patented by Mr. Louis L. Kaess and Armour Selley. Mr. Kaess has been building aeroplanes since 1911, his latest production being the well-known Continental pusher which proved to be the most successful pusher type machine turned out during the war. A description of this machine may be found in the December 31, 1917, issue of AERIAL AGE. He has also built many types of training and scout machines.



Armour Selley is well known in the model game. His former records, recognized throughout the world, stamp him as one of America's most successful model fliers. He has won six world records for model flying and during the war held a position with the Government as inspector of aircraft and was stationed at one of the largest and most important aeroplane factories. Mr. Selley's workmanship can be detected in the model shown in the picture, and this is sufficient assurance that the model is a record breaker in the hands of any intelligent boy.

The "Flying Model Airplane Corporation" is distributing these models to the different department and toy stores in each city, and they are sold for a reasonable amount.

The general dimensions are as follows:

Main wing spread	24"
Main wing curve	R.A.F. No. 6
Main wing chord	4 9/16"
Elevator wing spread	11"
Elevator wing chord	3 9/16"
Propeller diameter	8"
Propeller pitch	14"
Propeller thrust	4¼ ounces
Propeller speed	1000 R.P.M.

Power consists of ten twisted para rubber strands to each propeller and the rubber is 1/16 x ⅛ inch in cross section.

Plan view of the type F-3 monoplane built by the Flying Model Airplane Corp.

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Oh! the Deuce!

A team playing the local vaudeville houses chatters as follows:

"I see by the papers that the King and Queen of Belgium recently travelled to Paris in an aeroplane."

"So? (now here's where we come in) they must have had an Ace; that's the only thing to take a King and Queen."

Drafting Room Definitions

1. A drafting room is a place where the time between arguments is spent in making changes.
2. A tracer is a human being, who, knowing nothing himself or herself, never understands what the draftsman thinks he or she knows.
3. A designer is a bunch of erroneous ideas surrounded by the boss.
4. A data book is a collection of information nobody uses.
5. Tracing cloth is made to take the high spots of ink erasers.
6. A blue print boy is a skunk with a dirty face who smokes cigarettes, watches the clock, and sometimes makes a print.
7. A checker is a pessimist with a blue pencil, chronic indigestion, and no conscience; who spends his time trying to figure out the other way of doing everything.
8. The whistler is a form of the seven-year itch in its most aggravating form.
9. The chief is a lucky dog, who holds his job by taking credit for the ideas of his designer.

Take That

After a London air raid, a prisoner was charged with stealing a cover off a motor car.

"Have you anything to say in defense of your action?" asked the magistrate.

"Yes, sir," was the reply. "On the motor was a large notice wot said: 'Take cover,' so I just took it."—*Aircraft Rag.*

Grammatical Note

"King Flies From Brussels to Paris," says headline over account of Belgian ruler's trip. "King flees" is the more common phrase regarding movements of monarchs these days.—From N. Y. *Herald.*

From Any Pilot

Le Pere
Who art in Hangar 7,
Hallowed by thy paint;
Thy prop revolves at R.P.M.
In air as it does on the Dead Line;
Give me this day
My daily jazz,
And forgive me for trespassing against those who would trespass ahead of me,
And lead me not into tail spins
But deliver me from ground loops,
For thine is the speed, power and general pep
Forever,
Amen.

Sgt. Roy Harris Russ.

Bud Fisher, in the New York World, reveals the disadvantages of being a flying instructor

AEROPLANE INSURANCE

Merchants Fire Assurance Corporation of New York

This company issues policies covering aircraft against the following risks:

1—FIRE AND TRANSPORTATION
2—COLLISION (Damage sustained to the plane itself)
3—PROPERTY DAMAGE (Damage to the property of others)

Additional coverage may be had against loss by wind storm, cyclone or tornado.

We will be glad to discuss problems concerning aeronautic insurance.

AUSTEN B. CREHORE, Manager
For two years pilot Lafayette Flying Corps. Since 1910 employed by this company.

INDUSTRIAL DEPARTMENT

Cleveland Offers Many Inducements to Aircraft Industry

CLEVELAND'S situation on seven trunk lines, the B. & O., C. C. C. & St. L., Erie, N. Y. C., N. Y. & St. L., Pennsylvania, and W. & L. E., gives it a service second to none in reaching all points of the country, and on favorable rate adjustment Two of the six trolley lines operating from Cleveland augment the facilities by operating freight service. The city's situation on the lake affords via water routes overnight service between Cleveland and Detroit and Cleveland and Buffalo during the entire period of lake navigation. Regular sailings tri-weekly or better afford through service for freight traffic to Lake Superior ports. Cleveland can be reached over night from either the Atlantic seaboard or the Mississippi River, and one-half the population of the United States and Canada is within a radius of five hundred miles.

Cleveland, the industrial giant, owns or controls over two-thirds of all the shipping on the Great Lakes. It is the natural meeting point for Iron Ore from the upper Lakes and coal from Ohio, West Virginia and Pennsylvania fields, thus, it is no wonder that Cleveland out-ranks all other American cities in the production of steel ships, wire, wire nails, bolts, nuts, heavy machinery, vapor stoves, electric carbons, malleable castings, telescopes, printing machinery, and many other allied industries.

Cleveland has forged ahead rapidly in the manufacture of automotive products; automobiles, aeroplanes, tractors, et cetera. Aeroplanes are manufactured in Cleveland by the Glenn L. Martin Company. Motors and various kindred parts are turned out by a large number of engineering concerns on a production scale; Motor Products & Engineering Company, E. 61st Street and Curtiss Avenue; Weger Aeronautical Motor Company, 112 Hamilton Avenue; Western Machine Products Company, St. Clair and East 73d Street.

Cleveland has for many years been remarkably fortunate in having an excellent supply of high-grade labor at all times, yet without experiencing any large surplus, even in times of industrial depression. This fact may be attributed to (1) the great diversity of industrial activities, and (2) the attractive living conditions for working men.

Indicating the variety of skilled and unskilled labor available in Cleveland, here are a few of the industries in which Cleveland either leads the entire country, or takes a very high rank:

Astronomical Instruments, Automobiles, Aeroplane Parts, Bolts and Nuts, Carriage Hardware, Castings, Chemicals, Drop Forgings, Dry Batteries, Electric Carbons, Hardware, Hoisting and Conveying Machinery, Iron and Steel Products of all kinds, Knit Goods, Machinery, Metal Stampings, Oil Paints and Varnishes, Shipbuilding, Stoves, Wire, Wire Nails, Wire Fences, Wire Springs, Women's Wear.

Cleveland is the fourth city in financial importance. It is the seat of the Fourth Federal Reserve Bank, which has the third largest capital among the twelve Federal Reserve Banks.

Cleveland enjoys a temperate climate and has the lowest death rate of any of the largest cities. There are 614 miles of paved streets in Cleveland, the thoroughfares being exceptionally broad and straight. Forty-two miles of boulevards and 20 parks containing a total of 2,673 acres do much toward beautifying this flourishing city.

Cleveland is showing a remarkable growth in new factories, population, and area. The population as estimated January 1, 1919, according to the United States Census Bureau method, was 869,831.

Central News as saying with regard to Captain Alcock's achievement:

"It was a magnificent and very fine feat. I am very glad Captain Alcock was able to make the flight in real fashion without warships and all that sort of thing. It is very gratifying from that point indeed."

Congratulatory messages have been sent to Alcock and Brown by King George, General Seely, General Trenchard, and General Sykes. Major Kennedy, father of Miss Kennedy, whose marriage to Brown was postponed till after the flight, said his daughter was "very delighted, almost overwhelmed."

Secretary Daniels, in a press interview, said:

"The flight across the Atlantic of Alcock and Brown in a single 'hop' not only appeals to the imagination of every one but is a tremendous demonstration of the advance of aviation since the beginning of the war and a promise of still greater development in the future. It should inspire American aviators, too, but the development of aviation in the Navy cannot go ahead if the appropriation of $15,000,000 fixed by the House is not increased in the naval appropriation bill."

General Menoher, Chief of the Air Service, United States Army, said:

"I am very glad they have succeeded. There is only one thing that can be said on such an occasion and that is 'hurrah!' It is a great achievement when a bomber can fly across the Atlantic inside of a day and a night. It shows that Hawker had the right idea. The only trouble with his flight was that he had the element of bad luck in mechanical difficulty which forced him to bring his plane down. The element of luck was with Alcock and Brown in that they did not have difficulties of that sort.

"The flight of the Vickers-Vimy machine on top of the splendid performance of the NC-4 shows that the plan for the spanning of the Atlantic by air was feasible from the start. I will cable my personal congratulations to the two British fliers."

Rear-Admiral David W. Taylor, Chief of the Bureau of Construction and Repair, said: "It was a fine attempt and a splendid achievement, and deserves congratulations from all. They took a sporting chance and won."

By an interesting coincidence—inasmuch as it was the fate of a small minority of British war aviators—both members of the crew of the Vickers-Vimy biplane were taken prisoners during stirring careers on the fighting front. It would be hard to say which had the worst time of it. Captain Alcock fell into the hands of the Turks and Lieut. Brown became the prey of the Germans.

Lieut. Arthur Whitten Brown, navigator of the Vickers-Vimy, to whose skill and careful preparation a large measure of the trans-Atlantic flight's success is due, is an American. His birthplace was Glasgow, in 1886, but his father and mother were Americans, his father having gone abroad to inaugurate the manufacture of the Westinghouse automatic engine, now carried on by Vickers, Ltd. On coming of age Lieut. Brown claimed American citizenship, still retains it, and has no intention of relinquishing allegiance to the Stars and Stripes. He is a member of the Royal Air Force.

of Air Service, Washington, D. C.

Second Lieut. Samuel McCarthy will proceed to aviation repair depot, Speedway, Indianapolis, Ind.

Second Lieut. Thomas L. Lloyd, A. S. A., will proceed to Philadelphia, Pa., for duty in connection with hospital publications, and upon completion of this duty will return to his proper station, Washington, D. C.

First Lieut. Richard E. Lloyd is announced as on duty requiring to participate regularly and frequently in aerial flights from March 21, 1918, to July 12, 1918.

Second Lieut. Russel E. Powell, is relieved from duty with the Air Service, and will report in person to the commanding officer, military hospital, Cooperstown, N. Y.

First Lieut. David R. Shearer, will proceed to Park Field, Millington, Tenn., for the purpose of discharge.

Major Leo G. Heffernan, will proceed to Miami, Fla., take station, assume command of Chapman Field.

First Lieut. Frank M. Tierney, will proceed to the aviation repair depot, Speedway, Indianapolis, Ind.

Second Lieut. Edwin Johnson, will proceed to Dayton, Ohio, and will report to the chief, Engineering Division, for duty.

Second Lieut. Leo B. Gape, will proceed to Washington, D. C., and report to the Director of Air Service.

Lieut. Col. Davenport Johnson, Jr., will proceed to Chicago, Ill., on temporary duty for the purpose of conference with the department Air Service officer, Central Department; thence to Selfridge Field, Mount Clemens, Mich., take station, assume command.

Capt. Charles W. Drew, will proceed from Walter Reed Hospital, Takoma Park, D. C., to Selfridge Field, Mount Clemens, Mich., and report upon arrival to the commanding officer for duty with the first pursuit group at Selfridge Field.

Capt. Byron H. Mills, will proceed to Kelly Field, San Antonio, Texas.

First Lieut. Karl DeV. Fastenau, will proceed to Wilbur Wright Air Service Depot, Fairfield, Ohio.

EXTENSIVE PIONEER AEROPLANE TOURS TO BE ORGANIZED BY AERIAL LEAGUE

PIONEER aeroplane tours, similar to the Glidden Automobile Tours, which did so much to bring about the use of automobiles for pleasure and transportation, are being planned by the Aerial League of America as a means of enabling those who feel the call of the air to participate in pleasure aviation events as well as to create a market for surplus military and naval aeroplanes, and aeronautic equipment.

The Aerial League, of which Rear-Admiral Robert E. Peary is president, has canvassed part of the 30,000 ex-Army and Navy reserve aviators, and the 34,000 Army cadets who were under training for the Air Service when the war ended, and has found that many are anxious to participate in such tours.

These 64,000 aviators and cadets are all college men, and besides being directly interested in aviation themselves, have parents and friends who have been anxious to make flights but could not do so because Army regulations do not permit taking civilians for flights in military aeroplanes.

From the canvass made it was found that many would like to participate in these tours for sport and pleasure; others would like to participate as a means of continuing their aeronautic activities and remain connected with the aeronautic movement, so as to be ready for whatever business opportunities the development of aeronautics may bring; others are interested for technical and scientific reasons, and see in these tours an opportunity of obtaining actual data regarding the cost of operation of aeroplanes for sport as well as for transportation, and of determining the financial basis of aerial transportation; others are interested because it is a pioneer movement which will do much towards bringing about the use of aeroplanes for general purposes and therefore should be supported.

Use of Surplus Military and Naval Aeroplanes and Equipment Will Bring Pioneer Aeroplane Tours Within Means of Hundreds

The use of surplus military and naval aeroplanes and aeronautic equipment, which can be had at low cost, will bring the pioneer aeroplane tours within the means of hundreds of people interested in aeronautics for the reasons given above.

The Pioneer Aeroplane Tours will create a market for surplus military and naval aeronautic equipment.

The Army has thousands of aeroplanes and motors, and spare parts, instruments, accessories and materials for thousands more. The Navy has over one thousand aeroplanes stored away, hundreds of which will deteriorate unless used, and, according to Washington reports, are to be sold.

The Army has already sold over two thousand of the idle aeroplanes and close to five thousand motors, which are being put on the market at prices comparing favorably with the price of the average automobile.

Aeroplanes Can Be Rented for Tours

To assist this project, the Curtiss Aeroplane & Motor Corporation is putting into effect a plan which will enable aerial tourists to rent an aeroplane for one, two or three months, and participate in the Pioneer Aeroplane Tours at a cost of less than two thousand dollars ($2,000) for two people, including the cost of the insurance for the aeroplane, the pilot and the passenger.

Will Establish Municipal Aviation Fields Throughout the Country

Landing places are to the aeroplane what good roads are to the automobile. To bring about the use of aeroplanes for general purposes it will be necessary to establish flying fields throughout the country, as near to the cities as possible, to facilitate air travel.

Hundreds of cities all over the United States have applied to the Aerial League of America for assistance and advice in establishing municipal flying fields, and are ready to establish them.

The Pioneer Aeroplane Tours will give the necessary incentive to bring prompt action in establishing these fields, and whereas the aerial tours are to extend throughout the United States and will include seaplane tours also, it is expected that in a short time there will be a sufficient number of flying fields for aeroplanes, and seaplane stations for seaplanes, to permit the employment of aircraft for transportation and general purposes.

Plans for the Aerial League of America's Pioneer Aeroplane Tours

(1) The Aerial League of America's Pioneer Aeroplane Tours, which are on the plan of the famous Glidden Automobile Tours, are to start this summer and continue weekly throughout the year, extending South as cold weather comes.

(2) The tours start with aeroplanes of "economic" type, such as aeroplanes equipped with motors from 90 horsepower up, of which the Government has thousands for sale.

(3) Every effort will be made to create a market for the surplus Army and Navy aeroplanes, motors, accessories and aeronautic materials.

(4) When it becomes feasible, larger aeroplanes will be admitted. Then it may be well to have different classes of entrants, allowing 50 horsepower additional for every extra passenger carried. In other words, if the maximum horsepower allowed for two people is 150 horsepower, then a 200-horsepower machine must carry not less than three people and a 250-horsepower machine must carry not less than four people, a 300-horsepower machine must carry not less than five people, and so on, allowing 50 horsepower for every additional passenger.

(5) Seaplane tours or cruises will be started as soon as possible.

(6) To begin with, the tours will be divided into four classes, as follows:

(a) One-day tours, for people who can only spend one day a week.

(b) Week-end tours, which will last from Friday to Sunday or Monday, for people who can only spend their week-end.

(c) "Vacation week tours," which will last one week, for people who wish to spend a week of their vacation in aerial touring.

(d) Three-thousand-mile tours, which will last ten days, for people who wish to spend two weeks of their vacation in aeroplane touring.

(7) One of the aims of the tours will be to open airways for air travel, and establish supply stations throughout the country for air travelers.

(8) The average travel for one day in these aerial tours will be 250 miles, which is less than four hours in the air, so as to afford plenty of time each day for the aerial tourists to "take in" other diversions, such as tennis, golf, swimming, motoring, riding, etc., wherever they stop.

(9) Expert mechanics, spare parts, fuel and supplies will be provided at the stopping places, where necessary repairs will be made, tanks filled and aeroplanes attended to at the lowest possible charge.

(10) Headquarters for these tours have been established in New York and at Atlantic City, at the Atlantic City Airport, which, being the civilian aeronautic center of the United States, and being ideally located geographically, will become the starting place and terminus for the tours.

Headquarters for the tours will also be established in all the cities selected as the stopping places.

(11) These aeroplane tours will be led by squadron commanders, who will lead the touring planes in squadron formation in all the tours.

(12) Entries can be made by individual owners, aero clubs, newspapers, States, cities, chambers of commerce, rotary clubs, colleges, automobile clubs and other organizations, and by manufacturers. The entries must be addressed to the Chairman, Aerial League of America Touring Committee, Atlantic City Airport, Atlantic City, N. J.

Tentative Routes for the Aerial League of America's Pioneer Aeroplane Tours

250 Miles Tour to Last One or Two Days

In this tour the aviators will start from Atlantic City Airport, in formation, follow the coast, land at either Sea Girt or at Asbury Park or Keyport for gasoline, continue to New York, land on the New York Police Aviation Landing Place at Seventy-ninth Street, near Columbia Yacht Club, have lunch and fill the tanks. The New York stop may be made at Garden City and the aerial tourists may participate in sporting events being held there.

From New York follow air route over Elizabeth, New Brunswick, Princeton, Trenton; land at Philadelphia.

Start from Philadelphia and either fly straight to Atlantic City or to Wilmington, and return to Atlantic City.

On this route there are landing places practically everywhere, from thirty to fifty miles apart.

500 Miles Tour to Last Two or Three Days

In this tour the aviators will start from Atlantic City Airport, in formation, follow the coast, land at either Sea Girt or at Asbury Park or Keyport for gasoline, continue to New York, land on the New York Police Aviation Landing Place at Seventy-ninth Street, near Columbia Yacht Club, have lunch and fill the tanks. The New York stop may be made at Garden city and the aerial tourists may participate in sporting events being held there.

From New York follow air route over Elizabeth, New Brunswick, Princeton, Trenton; land at Philadelphia.

Stop overnight at Philadelphia. Start from Philadelphia in the morning, fly to Wilmington, then to Havre-de-Grace, then to Baltimore for lunch.

After lunch proceed to Washington (land at Bolling Field or College Park), and either stay at Washington overnight or fly back to Atlantic City by way of Annapolis and Dover.

750 Miles Tour to Last Three or Four Days

In this tour the aviators will start from Atlantic City Airport, in formation, follow the coast, land at either Sea Girt, or Asbury Park or Keyport for gasoline, continue to New York, land on the New York Police Aviation Landing Place at Seventy-ninth Street, near Columbia Yacht Club, have lunch and fill the tanks. The New York stop may be made at Garden City and the aerial tourists may participate in sporting events being held there.

From New York follow air route over Elizabeth, New Brunswick, Princeton, Trenton; land at Philadelphia.

Stop overnight at Philadelphia. Start from Philadelphia in the morning, fly to Wilmington, then to Havre-de-Grace, then to Baltimore for lunch.

After lunch proceed to Washington (landing at Bolling Field or at College Park).

From Washington proceed to Richmond by way of Fredericksburg, and from there to Newport News and back by following coast line, and making a landing at Cape Charles or Cape May.

1000-Mile Tour to Last From Four to Six Days

In this tour the aviators will start from Atlantic City Airport, in formation, follow the coast, land at either Sea Girt or Asbury Park or Keyport for gasoline, continue to New York, land on the New York Police Aviation Landing Place at Seventy-ninth Street, near Columbia Yacht Club, have lunch and fill the tanks. The New York stop may be made at Garden City and the aerial tourists may participate in sporting events being held there.

From New York proceed to Albany (landing on Municipal Flying Field); then proceed to Binghamton, thence to Ithaca, Rochester, Batavia, Erie, Cleveland, Pittsburgh, Uniontown, Cumberland, Brockton, Lancaster, Hagerstown, Washington, D. C.; Baltimore, Wilmington, Middletown, Mays Landing, Atlantic City Airport.

1,500-Mile Tour to Last From Six to Ten Days

In this tour the aviators will start from Atlantic City Airport, in formation, follow the coast, land at either Sea Girt, or Asbury Park or Keyport for gasoline, continue to New York, land on the New York Police Aviation Landing Place at Seventy-ninth Street, near Columbia Yacht Club, have lunch and fill the tanks. The New York stop may be made at Garden City and the aerial tourists may participate in sporting events being held there.

From New York proceed to Albany (landing on Municipal Flying Field); then proceed to Binghamton, thence to Ithaca, Rochester, Batavia, Buffalo, Brockton, Erie, Cleveland.

From Cleveland proceed to Toledo, Lima, Piqua, Dayton, Springfield, Columbus, Zanesville, Wheeling, Uniontown, Cumberland, Hagerstown, Lancaster, Washington, D. C.; Baltimore, Wilmington, Atlantic City Airport.

2000-Mile Tour to Last From Eight to Ten Days

In this tour the aviators will start from Atlantic City Airport, in formation, follow the coast, land at either Sea Girt, or Asbury Park or Keyport for gasoline, continue to New York, land on the New York Police Aviation Landing Place at Seventy-ninth Street, near Columbia Yacht Club, have lunch and fill the tanks. The New York stop may be made at Garden City and the aerial tourists may participate in sporting events being held there.

From New York proceed to Albany (landing on Municipal Flying Field); then proceed to Binghamton, thence to Ithaca, Rochester, Batavia, Buffalo, Erie, Brockton, Cleveland.

From Cleveland proceed to Sandusky, Toledo, Lima, Piqua, Dayton, Springfield, Columbus, Zanesville, Wheeling, Uniontown, Cumberland, Hagerstown, Washington.

From Washington proceed to Fredericksburg, Richmond, Newport News and back to Atlantic City, following the coast line, stopping at Cape Charles, New Church, Cape May, or by other cities inland.

2500-Mile Tour to Last From Eight to Twelve Days

In this tour the aviators will start from Atlantic City Airport, in formation, follow the coast, land at either Sea Girt, or Asbury Park or Keyport for gasoline, continue to New York, land on the New York Police Aviation Landing Place at Seventy-ninth Street, near Columbia Yacht Club, have lunch and fill the tanks. The New York stop may be made at Garden City and the aerial tourists may participate in sporting events being held there.

From New York proceed to Albany (landing on Municipal Flying Field); then proceed to Binghamton, thence to Ithaca, Rochester, Batavia, Buffalo, Erie, Brockton, Cleveland.

From Cleveland proceed to Sandusky, Toledo, Detroit, Hudson, South Bend, Terre Haute, Chicago. Then return by way of Joliet, La Salle, Peoria, Springfield, Ill.; St. Louis. From St. Louis to Effingham, Terre Haute, Indianapolis.

From Indianapolis to Dayton, Columbus, Wheeling, Uniontown, Cumberland, Hagerstown, Washington, D. C.; Baltimore, Wilmington, Philadelphia, Atlantic City.

3000-Mile Tour to Last From Twelve to Fifteen Days

In this tour the aviators will start from Atlantic City Airport, in formation, follow the coast, land at either Sea Girt, or Asbury Park or Keyport for gasoline, continue to New York, land on the New York Police Aviation Landing Place at Seventy-ninth Street, near Columbia Yacht Club, have lunch and fill the tanks. The New York stop may be made at Garden City and the aerial tourists may participate in sporting events being held there.

From New York proceed to Albany (landing on Municipal Flying Field); then proceed to Binghamton, thence to Ithaca, Rochester, Batavia, Buffalo, Erie, Brockton, Cleveland.

From Cleveland proceed to Sandusky, Toledo, Detroit, Hudson, South Bend, Chicago. From Chicago to Joliet, La Salle, Peoria, Springfield, Ill.; St. Louis. From St. Louis to Sparta, Ill.; Dexter, Millington, Tenn.; West Point, Miss.; Montgomery, Ala.; Americus, Ga.; Macon, Ga.; Augusta, Ga.; Columbia, S. C.; Pinehurst, N. C.; Raleigh, N. C.; Richmond, Va.; Fredericksburg, Va.; Washington, D. C.; Wilmington, Del.; Philadelphia, Pa.; Atlantic City.

While this route is most extensive, every place mentioned on this route, from St. Louis to Tennessee, Missouri, Alabama, Georgia, North Carolina, South Carolina and Virginia, has been used as a landing place by U. S. Army aviators, and is known to have a suitable landing field.

The News of the Week

Aviators of All Nations Eligible for $50,000 Trans-Pacific Flight

Los Angeles.—Licensed aviators of any nationality may compete in the proposed transpacific aeroplane flight for which Thomas H. Ince has offered a prize of $50,000 according to rules governing the contest made public recently. The flight may be attempted from either side of the Pacific, but if made westward Venice, Cal., must be the starting point and the landing made on the mainland of Australia, the Japanese Islands, or the continent of Asia. If made eastward, Asia, Australia, or Japan may be the starting point and the finish made on the mainland of the United States.

The contest will be open from next September to February, 1920. The flight must be completed within 12 days.

If the flight across the Pacific is not completed, Ince said, the aviator reaching the Hawaiian Islands in the shortest time would receive $10,000. If no contestant reaches the Hawaiian Islands the aviator who flies the furthest in that direction will receive $5,000.

Curtiss Triplane to Attempt Altitude Flight

Roland Rohlfs, test pilot of the Curtiss Company, will make an attempt this week to bring back to America the world's altitude record in a new Curtiss triplane known as the Wasp. The present record of 33,136 feet was made recently by the French aviator Adjutant Casale.

The wings of the machine have been specially modeled for fast climbing, and the new Curtiss "K" type of twelve-cylinder motor has been installed. The Wasp is a small machine, designed as a fighting 'plane for the Army, but was not completed until the armistice was signed.

Under official Government tests with a full military load it established the world's record in speed at 163 miles an hour. It also has established the climbing record, ascending 16,000 feet in ten minutes. The Washp is the smallest triplane in the world, measuring 32 feet across the wings. The length over all is 23 feet 3 inches, and despite the three wings she is but 9 feet 10½ inches high.

Cascade Mountains Crossed by Curtiss Biplane

Cle-Elum, Wash.—Lieut. Jay M. Felters, with Private Edward Kessel as passenger, crossed the Cascades from Seattle to this place at an altitude of 9,000 feet, covering the distance of 95 miles in 70 minutes. This is the first crossing of the Cascades from Seattle.

Captain Roy N. Francis standing in front of the Martin bomber, which he will pilot across the continent

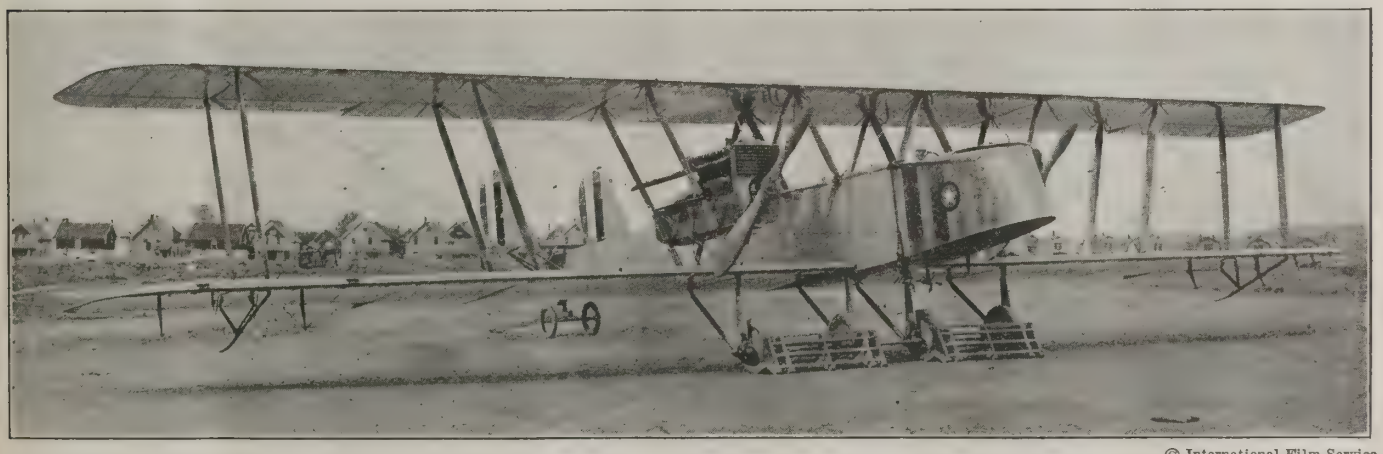
New York City Will Establish Landing Field

New York City.—At the request of Major Gen. Charles T. Menoher, Chief of the Air Service of the United States Army, New York City may construct a municipal landing field for commercial, mail and military aeroplanes. This developed recently at the meeting of the Board of Estimate, when Comptroller Charles L. Craig laid before the board a letter from General Menoher regarding the proposed field.

According to the communication from General Menoher, the Government has adopted a general policy to further the project. The General predicts that the development of aviation in the United States will be along both military and commercial lines. He states that the Post Office Department now finds it necessary to establish throughout the country terminal or way stations for its aerial mail deliveries, and joins with the Air Service in presenting the project to the attention of the city of New York.

According to the communication from the Director of Air Service, should the city of New York decide to co-operate with the Government in establishing landing fields, the army will obligate itself to furnish an expeditionary hangar to be erected on the field at the expense of the city. The army will request that the city bear the expense necessary for the establishment of the landing field, and the maintenance of both the field and the equipment, exclusive of aeroplanes.

The matter was referred to the Finance and Budget Committee.



The Queens Chamber of Commerce is fighting hard for the establishment of the municipal landing field within that borough. A field located there, according to the manufacturers, would not have the same advantages as one in Central Park, owing to the extra time taken to get to the heart of the city.

By draining the reservoir in Central Park, they assert, the present facilities for the public would not be interfered with. It would have the advantage of being free from trees, telegraph and power lines, tall buildings and other things that might make landing dangerous. There would also be ample room for the machines to take off.

Admiral Benson Urges Naval Aircraft Development

New York, N. Y.—Returning aboard the battleship Arkansas, Admiral William S. Benson, naval advisor to the American Commission for Negotiating Peace, and chief of operations of the Navy, urged the concentration of time and energy to the development of naval aircraft. The future of aeronautics in naval warfare requires that this arm of the service be extensively developed and that continuous research and development be continued.

"The thing that particularly interests me," said Admiral Benson, "is naval aviation. The Navy will devote much time and money to experiments in this field in the future, but there will be no daring attempts. We must rely on scientific data and the steady progress that they will give."

© International Film Service

The Martin bomber, which will be used for the trans-continental flight. It is powered by two Liberty motors

The 30-Passenger Caproni Triplane

WINGS have a total span of 96'-10". Overall length 49'-2". Height 24'-6". Wing Chord, 9'-1" and gap between planes, 8'-9". The wing area is 2,600 square feet. Weight, empty, about 14,000 pounds. Weight, loaded, about 25,000 pounds.

There are five Isotta Fraschini V 6 Type, 6 cylinder, 260 H.P. engines; the two inner engines at the nose of fuselage are placed in tractor position. Beyond each fuselage a streamlined nacelle is placed at either side below the middle wing with engines driving pusher propellers. The fifth engine is placed at the middle of the machine in the after part of the passengers' compartment and it drives a pusher propeller. The speed is about 105 miles an hour.

The passengers are seated side-by-side on the upper deck. The lower deck contains, besides accommodations for 22 passengers, a toilet room and a small car where drinks, sandwiches, etc., are served. The passenger compartment (room for 8 persons) on the upper deck, is used as a smoking-room.

The machine is designed for five engines of 400 H.P. each, and it can be equipped with Liberty "12's" or Eagle Rolls-Royce. Pending the installation of these engines, the machine is flying with the Isotta Fraschini engines.

Read and Towers to Be Greeted By Aero Club of America

New York, N. Y.—Arrangements for the reception of Commander John H. Towers, commander of the trans-Atlantic flying boat squadron, Lieutenant Commander Albert C. Read, commander of the successful NC-4, and Lieutenant Commanders Little and Richardson are being completed by a committee of the Aero Club of America. Commander Towers and his companions sailed from Brest aboard the American transport Zeppelin and are due to arrive on June 26.

The Aero Club of America announced the appointment of a representative committee of officers and members to take part in receiving the trans-Atlantic aviators. It comprises President Alan R. Hawley, Secretary Augustus Post, Rear Admiral Bradley A. Fiske (retired), Commissioner Murray Hulbert, Capt. Robert A. Bartlett, the Arctic explorer; C. J. Edwards, C. H. Harley, Mayor of Astoria, Wash.; Lieuts. W. B. Peabody, J. D. Hill, C. H. Payne, C. T. Kuhl, J. W. N. Richardson and Ensign J. M. Corbett. Several members have signified their intention of joining in the club's welcome.

As soon as arrangements can be made the Aero Club will tender a dinner to the commanders and crews of the NC-1, 3 and 4. The invitation was extended while the aviators were at Paris, and a wireless reply from Commander Read said their first duty would be to report to Secretary Daniels, and that arrangements for the dinner should be made through the Navy Department. A date will be fixed as soon as possible.

Aerial Patrol Ordered for Mexican Border

Washington.—Three aeroplane units of six machines each have been ordered by Director of Air Service Menoher to leave Kelly and Ellington fields, Texas, immediately to conduct observation work along the Mexican border.

Guardian Angel Parachute Tested at Atlantic City Airport

Atlantic City.—The "Guardian Angel" parachute, officially adopted by the British Royal Air Force as the most certain aerial life preserver yet invented, was demonstrated at the Atlantic City Airport on June 19 by Major Ordo Loos, R. A. F., and Miss Sylvia Boyden, of England.

They ascended to a height of one thousand feet in an aeroplane piloted by Eddie Stinson. After circling for a moment both Major Loose and Miss Boyden dove head first from the machine.

A big crowd, including many aerial experts, saw the parachutes open without a jerk and watched the demonstrators float gently to the ground. The tests will be repeated Saturday. Among those who witnessed them were Glenn H. Curtiss, Henry Woodhouse, of the Aerial League of America; A. S. Abell, 3d, of the Aero Club of America; Lieutenant G. W. Shaw, U. S. N., and Albert T. Bell, president of the Atlantic City Aero Club.

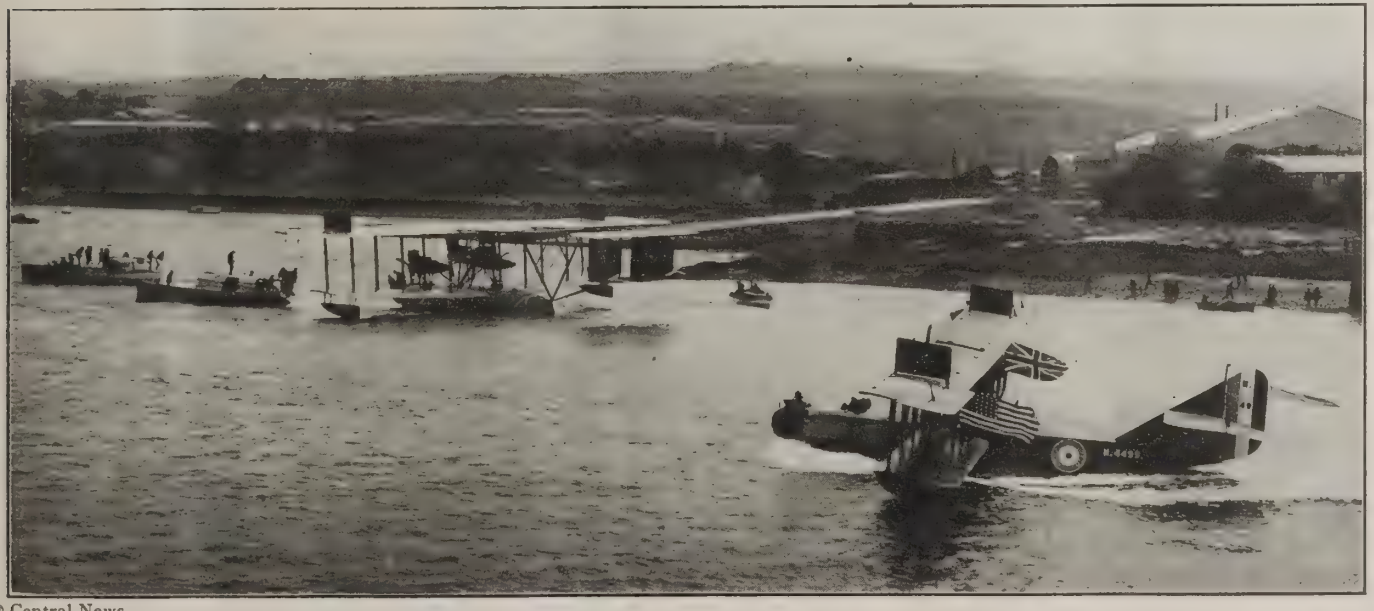
Petrova Visits Atlantic City Airport

Atlantic City, N. J.—Olga Petrova, the noted Russia dramatic star and screen artist, visited Atlantic City's Airport recently and displayed a deep interest in the various types of machines there. She took a flight with Eddie Stinson, the noted acrobatic flier, and expressed very aptly the contrast between flying in the enclosed machine of to-day as compared with her first flight in an exposed machine.



A Challenge to Parachute Manufacturers

Atlantic City.—A challenge to American makers of parachute aerial life preservers was issued to-day by Major T. Orde-Lees, the British parachute expert, who is at the Atlantic City airport, where he will demonstrate the British parachute known as the "Guardian Angel." The challenge is issued to prove by competition the superiority of the "Guardian Angel" parachute as a life preserver for aviators and air travelers.

Major Orde-Lees gives the selection of Monday, June 23rd, and Thursday, June 26th, for the competitions.

The challenge was telegraphed by Major Orde-Lees to Lawrence Sperry, Farmingdale, Long Island; Lieut. Jean Ors, the French parachute expert, who has been demonstrating his unique device at the Atlantic City airport; W. L. Watkins, who also displayed his 'chute at the local field, and the Irving Airchute Co., 523 Main St., Buffalo, N. Y.

The public and the aeronautic and military and naval authorities have been invited to witness the demonstrations.

The NC-4 floating safely on the waters at Plymouth

THE NEW CURTISS WIND TUNNEL

THE wind tunnel has been employed by the Curtiss organization as a means of verifying aeronautical design since 1908. Two tunnels of two and four foot diameters respectively had been built and used up to 1918. The four-foot tunnel is still in active service at the Curtiss Engineering Company's plant at Garden City, L. I., and the two-foot mechanism is used for qualitative experimentation as well as for exhibition purposes. Both, however, have been supplemented to a large extent by the new seven-foot tunnel which was planned in 1918 and completed early in 1919. This is believed to be the largest and most efficient device of its kind in the world.

In describing this new tunnel it will be desirable to recall certain facts about the wind tunnel in general. The chief purpose of the apparatus is, as the aeronautical reader knows, to test out the efficiency of an aeroplane or aeroplane element design before production is begun, as well as to afford a means for carrying on aeronautical research. Such a test is effected by sucking a stream of air through a tunnel or tube-like structure past a small model of the contemplated aeroplane or aeroplane element, and registering, through mechanical devices, the various effects of the air in pounds of force on the model. The air rushing by the model produces the same result as if the model were passing through the air. Effects in lift, drift and equilibrium can be accurately measured and studied. Nor is it necessary to make the test at the speed in miles per hour at which it is desired to fly the full-size aeroplane. Data obtained from a slower speed can be made the basis of prediction for any velocity contemplated.

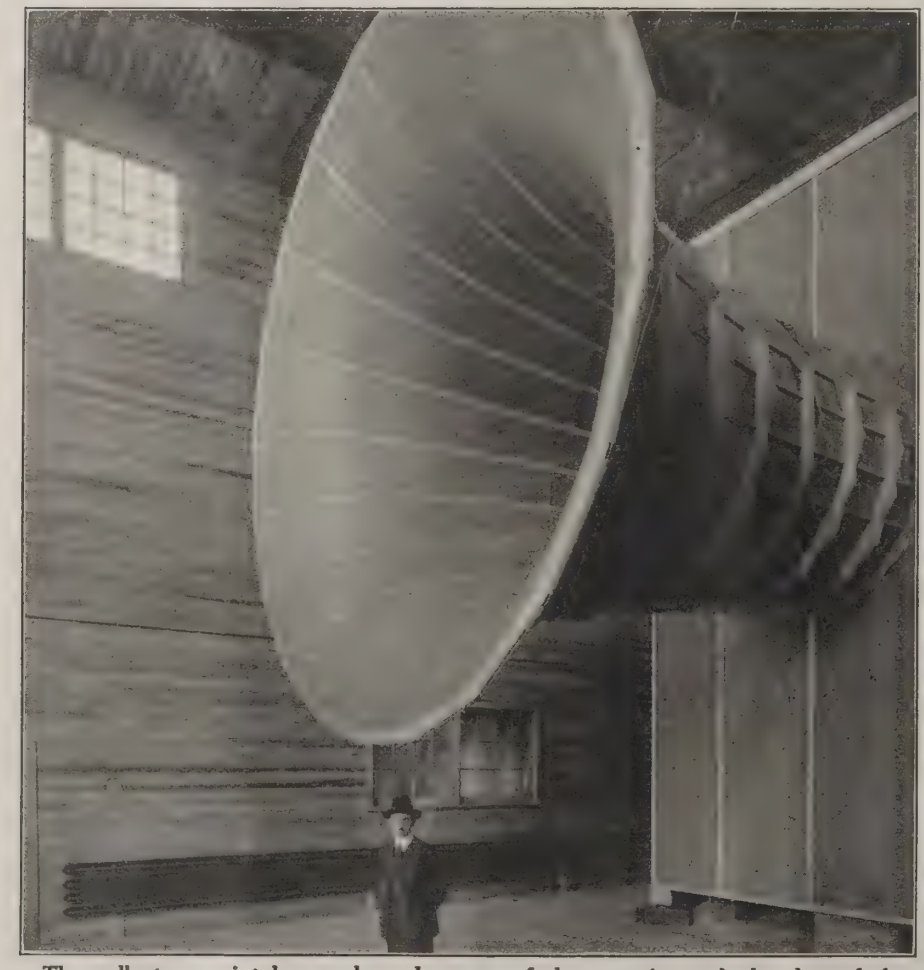
A wind tunnel is in principle a single continuous tube, but this tube is divided into three sections. They are termed the collector, the experimental or test chamber, and the diffuser. The motor operates at the large end of the diffuser, sucking the air through the collector, experimental chamber and diffuser towards itself.

The new Curtiss tunnel is suspended on steel cables from the ceiling of a room 103 x 30 x 35 feet. The suspension device allows a perfectly free and symmetrical circulation of air back from the point at which a 400 H.P. motor with a three-bladed propeller sucks it to the horn-shaped mouth of the collector, where it is again drawn into the tunnel. This method of support, which is one of its novel features, has given excellent results.

The collector portion of the tunnel is 15 feet long. The entrance diameter is 17 feet; the diameter at the wall is 7 feet. The shape is determined mathematically. The cross section is a twenty-sided polygon. The wooden rings are constructed by placing together two ten-sided polygons and rotating one relatively to the other. This construction is exceedingly strong and rigid. The air pressure on the walls of the experimental house is about 36 pounds per square foot when the wind speed is 100 miles per hour. The air then passes through a honeycomb which produces a straight, uniform flow of air at the point where the model is supported just beyond.

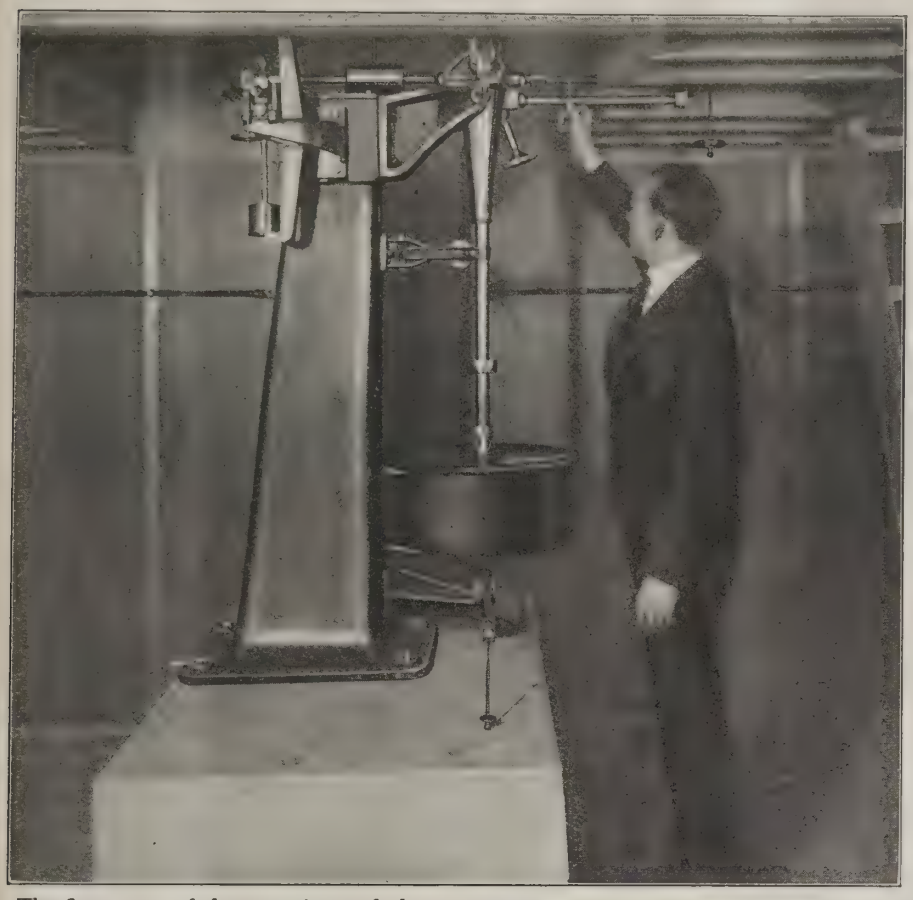
Models used for this purpose must be constructed with the greatest accuracy in order that the results obtained from them may be reliable when applied to the full size aeroplane. They must be made absolutely to scale; the dimensions of the wings, struts, tail surfaces, etc., being reproduced to one-thousandth of an inch.

The effect of the air current is to produce a lift and a drag on the model, which quantities are precisely measured by moving weights along the weight arms of the balance. The only part of the balance extending into the wind stream is a rod or spindle on which the model is mounted. The correction for the effect on wind flow on this spindle is easily made.



The model, sometimes as large as three feet in span, is attached to a steel vertical arm or spindle which holds it at the center of the air stream. It is at the forward end of the experimental chamber. The chamber has a length of fifteen feet and a width of thirteen. It is thus of much greater diameter than the rear end of the collector, or of the diffuser, which, starting at the front end with a diameter of eight feet, gradually enlarges until at the motor end it is twelve feet in diameter. The diffuser is thirty-seven feet long.

The four-foot tunnel is of another type —the enclosed type—in which the experimental chamber is of the same diameter as the diffuser and the small end of the collector. This, in the opinion of those who constructed the Garden City wind tunnel, has several disadvantages.



For instance, it restricts narrowly the size of the model. Every model causes some displacement of air. Displacement tends to cause an expansion of the cross-section of the air stream. With very small shapes the bad effects are negligible, but as the model grows larger it creates sufficient displacement to cause air-packing against the tunnel sides, and consequently a type of flow different from that actually obtaining in free air. In the Eiffel type of tunnel displacement can occur without this interference with the air stream. The air column keeps rather closely the form in which it leaves the collector. The diameter of its cross-section is thus approximately seven feet. Passing through a chamber whose cross-section has a diameter of thirteen feet, it has room for expansion.

Another disadvantage of the enclosed type may be noted. The air stream completely fills the tunnel. The manipulator is thus forced to stand outside. As a consequence, adjustment of the model is made so difficult that in order to effect it the motor operating the tunnel is usually shut off. In the Eiffel type, however, the manipulator stands inside the tunnel in the experimental chamber. From his place just outside the air column he can reach out and adjust the model at will.

The experimental chamber extends above and below the tunnel itself, and rests on the floor instead of being suspended by wires. It is composed of three stories. The first is below the tunnel, and contains the base of the pedestal or balance, by which the forces exerted on the model are measured. The aerodynamic balance is mounted on a concrete pedestal and the vertical arm of the balance extends thru an opening in the floor to support the model in the air stream above. A dash pot damps out the oscillations of the bal-

The collector or intake nozzle and a part of the experimental chamber of the seven-foot Curtiss Wind Tunnel. The mouth is 17 feet in diameter.

The first story of the experimental chamber in the seven-foot Curtiss Wind Tunnel, showing the uni-pivotal measuring balance, the spindle of which, projecting upward into the stream of air above, supports the model.

ance. By means of this sensitive instrument the air forces in any direction on the models are accurately measured. The rotating forces or moments on the models are also measured. The second story comprises the tunnel, into which the model projects. Air to the middle compartment of the Experimental Chamber is led through a metal honeycomb screen which serves to straighten out the air stream flowing in thru the collector just before it flows by the model. The air stream passes across the chamber as a cylinder about 7 feet in diameter at adjustable speeds controlled by the operator stationed below at the balance. The chamber is lighted electrically, and provision is made for power outlets. Direct, alternating and three-phase currents are available for propeller testing, pump testing and other experimental purposes. It also has a switch for electrical control of the motor, a Krell gauge to indicate the existing wind speeds. The third story is above the tunnel with a sliding platform from which shapes can be suspended into the air stream.

The balance used is a specially designed uni-pivot type which measures forces to less than .0001 of a pound. Air speeds up to 100 M.P.H. are now obtainable and it is expected to exceed this shortly.

The new Curtiss wind tunnel is the result of a long period of study of wind tunnel types. Data was collected on the Massachusetts Institute of Technology, Washington Navy Yard, Eiffel and other European tunnels, and an effort was made to avoid past mistakes and register an advance in scientific accuracy. The tunnel, for instance, was given a large room space, and every effort was made to get a clean and uniform return of air from diffuser to collector ends. The ideal wind tunnel would stand in free air except that free air is seldom calm. The best substitute for a calm, windless open is a large chamber in which the air supply is ample. but not subject to disturbance. Such a condition has been created for this tunnel.

In the experimental chamber of the new apparatus tests can be carried on with regard to skin friction, dirigible shapes and fuselage struts, the effect of additions to the body of an aeroplane, new wing section, propellers, gas pumps, etc., One of the most interesting works of the Curtiss staff is the sending of a standard wing section to various wind tunnel laboratories in the United States and Europe. Reports are being requested on this shape from each laboratory, and it is expected that the results will be valuable as indicating the type and degree of variations which must be expected.

The purpose of the wind tunnel being to check up on designs, it is interesting to know that there has been no recorded instance of a wind tunnel test made in one of these tunnels failing to tally with the later performance of a full-size machine.

No Curtiss model tested in miniature and pronounced satisfactory has failed to fly according to promise. The wind tunnel tests have been 100 per cent. reliable. This is a fact of high significance, indicating as it does that the aeroplane is on a thoroughly scientific basis even before the first lumber has been milled for it or the first fittings cast.

Such results are of inestimable benefit to the designers, and to the pilots who thoroughly test out the full-size machine before production and sale.

THE WHITTEMORE-HAMM MODEL-L BIPLANES

THE Whittemore-Hamm Type "L" Aeroplanes are tractor biplanes. They are all of the same dimensions, but with different engines as follows: The L-2 has a 90 H.P. engine; L-3, 100 H.P. engine; L-4, 125 H.P. engine; and L-5, 150 H.P. engine.

The engines used are Curtiss, Hall-Scott and Hispano-Suiza.

The following specifications for the L-2 apply to the other machines in so far as dimensions are concerned.

General Specifications

Span, upper plane	36′ 4″
Span, lower plane	30′ 4″
Chord, both planes	5′ 6″
Gap, average	5′ 6″
Length overall	25′ 6″
Incidence angle	3 degrees
Dihedral, lower plane	2½ degrees
Engine, Curtiss or Hall-Scott	90 H.P.
Endurance	2½ hours
Gross load	1850 pounds
Useful load	600 pounds

Wing construction is conventional, but all hinged surfaces are fastened by fittings which make a tight connection, leaving no gap which generally exists in biplanes. There is no center section. The upper wings are connected to a pair of "A" struts over the cockpit.

The fuselage has five ash longerons running from nose to back of rear cockpit. These longerons run into a three-ply laminated wood construction, the cross section of which is egg-shape. This section is built up under pressure of hot glue, lined and covered with linen. Four spruce longerons are glued into this laminated wood part. They are attached to the forward upper ash longerons by means of steel plates. The fifth or lower longeron makes a keel which results in a deep cockpit, and at the same time permitting a reduction in head resistance.

The rear or laminated part of the fuselage has no wires in compression members, thereby doing away with all care for this part of the body.

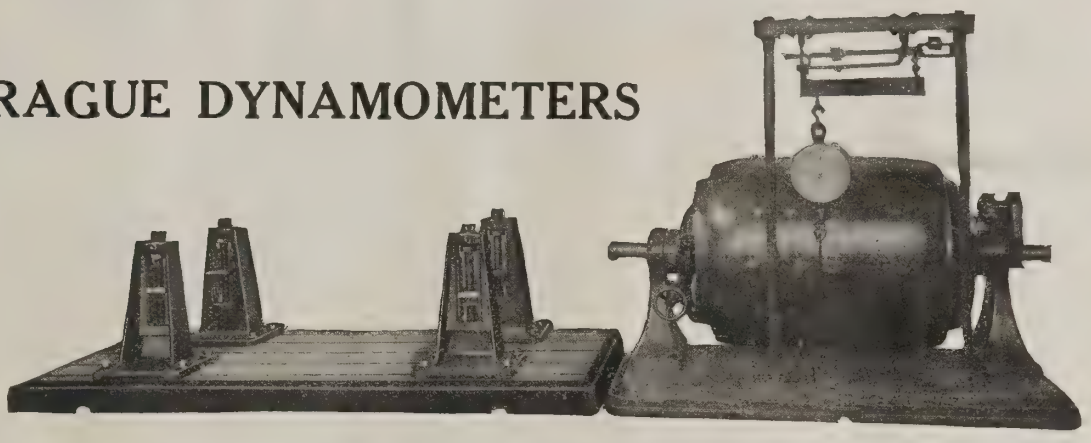
Flaring ailerons are used on upper planes only. Operating cables from under side of top plane enter side of body at points below rear cabane struts. Dual Deperdussin wheel-control is installed.

In the interplane bracing system, both flying and landing cables are double. The overhang on upper plane is supported by streamlined steel tube braces.

The landing gear is a departure from the practice generally employed. There are six struts in all; forward struts attached to the body at lower side longerons; middle and rear struts, which are of inverted V formation, attach at the lower or "keel" longeron. Landing forces are thus transmitted to the body with advantageous distribution. The usual rubber shock-absorber elastic is used covered with a streamline aluminum housing.

The Whittemore-Hamm L-2 Biplane won a trophy and the $1,000 cash prize offered by the Boston *Globe* for the aviator making the best record in a flight between Atlantic City and Boston during the month of May.

Piloted by Melvin W. Hodgdon, the L-2 made the flight from Boston to Atlantic City in 3 hours and 29 minutes actual flying time. Full time consumed in the flight was 5 hours and 15 minutes, which included a stop of 1 hour and 16 minutes at Central Park, L. I., where extra fuel was taken aboard for the continuation of the flight.



The L-2 was designed by Dr. Whittemore and his partner, Mr. Hamm. Both these men became interested in aviation as a result of the Harvard-Boston Aviation Meet at Squantum, Mass., in 1910-1911.

Hodgdon has been flying for about six years with the Whittemore-Hamm Company. During the war he was a pilot and instructor at one of the Government flying schools in the South.

THE SPRAGUE DYNAMOMETERS

400 H.P. aeroplane engine dynamometer with engine base supports

STARTING with one installation in 1906, several hundred Sprague electric dynamometers are now in use. They have played an important part in the development of aeronautical engines and apparatus and are recognized as standard laboratory equipment for the testing of engines by manufacturers, technical schools and Government experimental stations.

The electric dynamometer is a machine for measuring torque. The engine in test is coupled to the internally revolving rotor of the dynamometer, which transmits the full torque exerted by the engine to the external field or oscillating frame by electromagnetic interaction. The oscillating field frame is balanced on ball-bearing pedestals and is restrained from revolving by the scales on which the torque is measured.

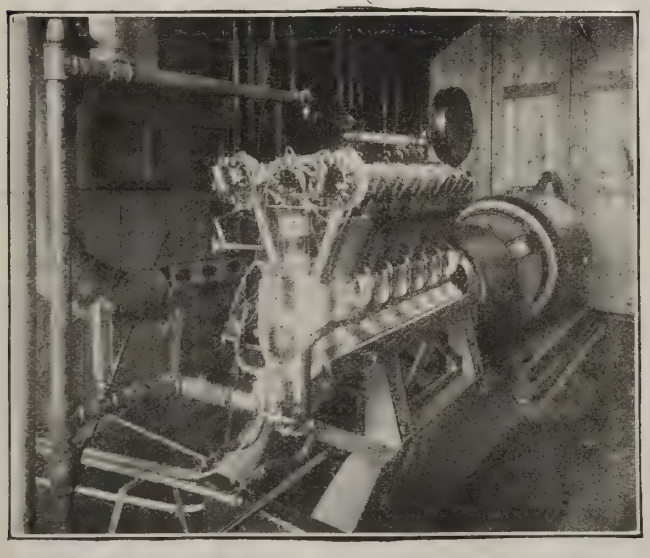
Horsepower is the product of torque and speed. Specifically for a dynamometer,

$$\text{Horsepower} = \frac{\text{R.P.M.} \times \text{lbs. pull} \times \text{torque arm in feet}}{5250}$$

By making the torque arm, or distance between the point of application of the scales and the center of the shaft, a certain length, the horsepower formula is simplified.

For the dynamometers described in this article the formulas are:

$$\text{H.P.} = \frac{\text{pounds pull on scales} \times \text{R.P.M.}}{1000}$$

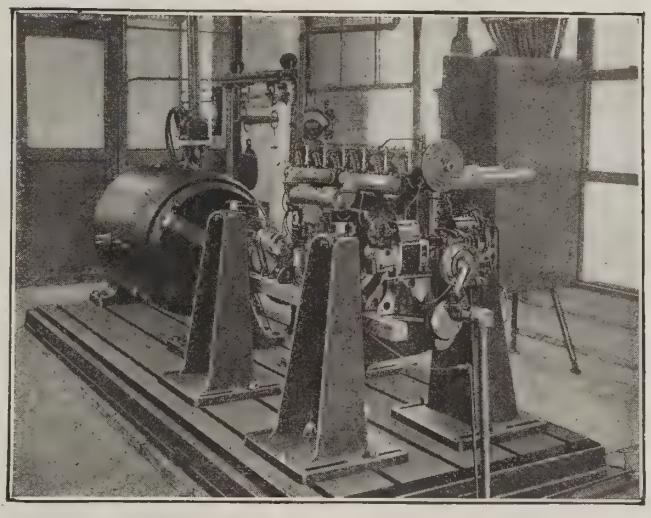


with some scale arrangements, and with others:

$$\text{H.P.} = \frac{\text{pounds pull on scales} \times \text{R.P.M.}}{3000}$$

These simple formulas can be worked out or a straight-line power-chart used.

The electric dynamometer requires a source of separate excitation for the fields at either 115 or 230 volts direct current. In special cases the dynamometer may be made self-exciting, but its speed range under these conditions is limited, and, except for production tests, separate excitation is essential. The power required for excitation of the fields is extremely small. A larger source of supply however, is required where the dynamometer is used as a motor.



Dynamometers are built in sizes ranging from 1 H.P. to 1,000 H.P. The sizes most used range from 50 H.P. suitable for engines having a maximum torque of 50 to 200 foot pounds up to 400 H.P. machines for engines with a torque capacity of 800 to 1,600 foot pounds. In testing very large capacities two or more dynamometers can be coupled in tandem.

U. S. Liberty 12-cylinder aircraft engine in test with Sprague Electric Dynamometer

The maximum speeds range from 4,000 R.P.M. on the 50 H.P. machine to 2,500 R.P.M. on the 400 H.P. machine.

The Sprague dynamometer may be run as a transmission dynamometer for starting the engines in test, and also for measuring the friction horsepower and so determining the mechanical efficiency. For such operation the requirement is an adequate supply of direct current at either 115 or 230 volts. For friction horsepower tests the supply of direct current available should be at least 25 per cent of the maximum capacity of the engine to be tested.

A Hall-Scott engine being tested on a 200 H.P. dynamometer at the Dayton Engineering Laboratories

Dynamometers for laboratory installations, fitted with the automatic control and a wide range rheostat capacity, are capable of variation in load and speed through a range as great as can be carried by any engine within the maximum capacity of the dynamometer. Operated as a generator or brake, the speed can be controlled from practically a standstill up to a maximum of 2,500 to 4,500 R.P.M., depending upon the particular dynamometer in use, through a very great range of speed and by such fine and gradual increments that any desired speed can be obtained. If backed up with direct current power of sufficient capacity the speed range as a motor or transmission dynamometer is nearly as great.

Throughout the speed range the dynamometer can be made to resist to its full rated torque capacity, where required. In practical service the equipment is laid out for full torque capacity through an intermediate range, but by special provision in the resistor design, full torque capacity can be maintained from zero to maximum speed, with short time overload torque capacity up to the limit of the dynamometer.

As a result of this great flexibility of control, it is possible to study the performance of engines beyond their ordinary limits of load and speed, and it is possible on one dynamometer to conduct tests on a wide variety of engines, both large and small and both high speed and low speed.

THE PHYSIOLOGY OF FLYING

By W. GUY RUGGLES

Originator and Inventor of the Ruggles Orientator

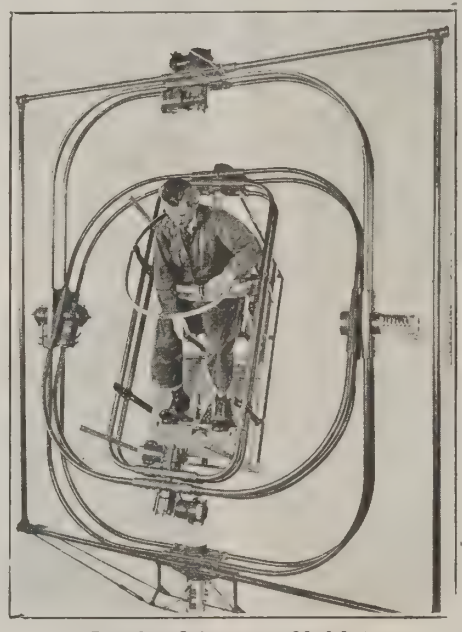
THE most complex handiwork of the Creator is man. Groping mentally upward in the dawn, he early learned to articulate something that meant "why" and enlightenment has steadily followed. By force of will and mind power he has prevailed over the entire animal kingdom, constantly adding to his mental development and physical comfort through the centuries.

Essentially a land animal, the seas tempted him and he devised means for navigating that unnatural element.

Comparatively slow of travel movement, he has, ever since that fateful moment in which he conceived his first thrill of speed—perhaps on some icy slope—compelled the swifter animals, and still swifter inanimate elements of nature, to provide him with an ever-increasingly rapid means of locomotion, until with a genius and courage that almost defies practical imagination he launched himself off the earth and water and at still greater velocities is realizing another step in his progress by conquest of the air.

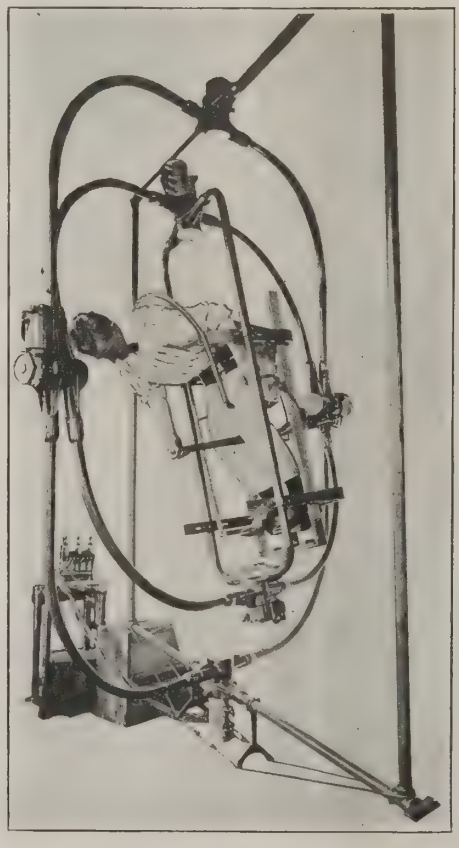
In all the history of the human race there is no more romantic narrative than the story of man's attempts to master the many problems involved in flying through the atmosphere, and those of us who have been interested in the dream of flight since childhood will never forget the elation we felt when the announcement was made, "The Wright Brothers Are Flying."

The progress made in the art since that momentous event is almost beyond comprehension. By directing according to his will the elements he exceeded in swiftness and strength all the creatures of the earth and sea, and he has already excelled in fleetness and power all the bird creations of the air.



Deep indeed is the reverence we feel for the genius that made man's dream of flight into a splendid accomplishment. The man of the world has caught the spirit of the future more than we realize. Men are going to fly: the active business man to keep vital engagements—as for instance in New York, Boston and Philadelphia or Washington the same day; deliveries by air mail; others will fly entirely for recreation in order to effect the widest possible change from the business routine, and long for an hour in the clean, wide spaces of the blue sky with its expanded horizon outlook on life, and a plunge through the fleecy clouds. Be the costs or the risks what they may, the present and future generations will not be denied these opportunities.

We cannot, however, and should not if we could, forget the disasters that have cost the lives of many brave and some very skillful men while advancing the science of aviation.



About ninety per cent of the fatal student-aviator accidents are due, a United States Army officer has stated, to mistakes or shortcomings of the man in the plane. Why does he make those mistakes; what are they? Unfortunately the man that survives a crash usually seems hazy about how it happened.

As a child, the writer had the good fortune to associate with surgeons and physicians and become interested in some of the problems and mysteries of animal life. Later when the rare privilege came of meeting and studying the performances of such men as Ely, Parmalee, Latham, Radley, Beechy, and many others, and I made an effort to analyze the cause of the regrettable accidents that deprived the art of some of the bravest men that ever lived, extensive study and experimentation beyond the scope of this paper resulted in the firm conviction that piloting a plane involved a problem in physiology differing essentially from the customary activities of mankind.

To the accomplished aviator piloting a good plane at moderate altitude is about as simple as walking on the earth. Between his first flight and that degree of perfection some very perplexing and unusual problems have been mastered by the student-aviator. Discovery of the reason for some of these things seems to be quite recent. Valuable information on the subject is also to be found in the records of research work done by scientists a hundred years ago.

Ruggles Orientator—Model 1

Ruggles Orientator—Model 2

Relieved of technical terms, walking, running over uneven surfaces, riding a bicycle, or similar activities may be considered as the result of muscular action directed by the brain. The marvelous beauty and intricacy of the organism by which the brain receives and verifies by comparison, the information it receives from the sensory organs, and endeavors to make corrections for errors as the muscles go into action, unfolds to the student as one goes more deeply into the subject.

Man has been popularly accredited with five senses: sight, hearing, smell, touch and taste. These sensory organs send to the brain information that falls within their limitations. When a subject may be sensed by more than one of these senses the brain, it appears, verifies the report of one sensory organ by "checking" it to the report coming from a different organ that perhaps sends information of an entirely different character, but most useful for a comprehensive understanding of the subject. Naturally the more reports that can be received the more thorough and complete the knowledge.

Loss of one or more of these sensory organs impairs this wonderful faculty and limits its scope. For illustration, loss of hearing eliminates the enjoyment of music, but the same individual enjoys fruit in all its beauty of coloring, contour, fragrance and flavor. The loss of sight limits one's enjoyment of fruit to contour, fragrance and taste, but the loss of sight in no way impairs one's enjoyment of music.

A little thought will convince us how wonderfully these senses combine in our daily activities and mention is made of them here because of the very important part some of them play in flying.

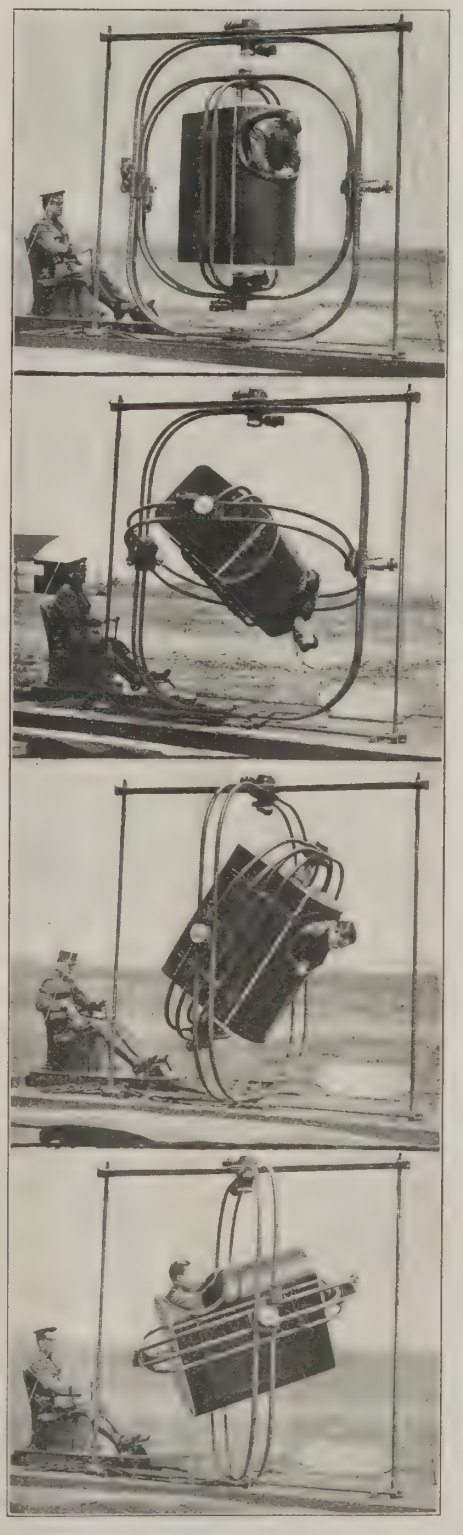
In addition to these commonly accredited senses man also possesses another most important faculty—that of orientation and equilibration. Sight and touch—including the muscle joint sense of body position—play important parts under varying circumstances, but the especial sensory organ of this faculty is the semicircular canal system of the inner ear with its ampaula, otoliths, and nerve ends, collectively called the static labyrinth to differentiate it from the aural labyrinth with which it is most closely connected.

Briefly, this organ consists of a membraneous sack out of which extend three membraneous canals lined with delicate nerve ends. These canals project around in a semi-circular shape and at the end are bulged out into an enlargement, something like the bulb of a thermometer, called the ampaula, which also contains a mass of nerve ends in the midst of which lies an otolith of limestone substance. Just beyond the ampaula the canals narrow and are again joined to the sack at a distance from their beginning, permitting them to describe some two-thirds of a circle in size, about that of the end of a leadpencil. They are so projected that

they lie in the three dimensions of space, i. e., each at right angles to the others, and the lymph that fills the sack also flows through and fills the canals.

From the ampaula end of the canals trunk nerves are bundled together to lead to the brain, and the entire organ as a unit is surrounded by the bony labyrinth to which it is attached at intervals to hold it in position, and protected in all its wonderful delicacy by the lymph that fills the intervening spaces of the bony labyrinth in which the membraneous labyrinth floats.

This organ is a part of the inner ear of birds and other animals, one being in each side of the head directly opposite the other in its relative position, and so placed that when the animal is in a natural position two canals lie in the horizontal plane sensitive to rotation about a vertical axis, and two stand in a vertical plane sensing rotation about a horizontal axis, and two are in the lateral plane sensing rotation about an axis at right angles to either of the others. Rotation of this organ causes a movement of the lymph in the canals which is sensed by the delicate nerve ends lining the canal and transmitted to the brain. Compound rotational movements are sensed by the various canals as they come into the plane of rotation, no movement being too intricate to escape detection. The nerve-ends of the ampaula sense the pressure of the otolith lying in their midst as it is acted upon by the pull of gravity, or by the inertia of changing velocity, or the difference between centrifugal force and the pull of gravity which indicates the correct banking angle while making a turn.



So important to life is this sense that scientists tell us it is present, in modified forms, in organisms that are not supplied with the other senses. It is of such importance to animals that it is protected by the densest bony covering in the body and operates largely through the involuntary brain. We are conscious of its activities by manifestations upon the bodily organism.

It is this little organ that enables us to stand upright on uneven surfaces in the dark and to decide quickly which of several uneven lines stand vertical. The deaf mute—born without this organ—appears to compensate for its absence by exercise of the sense of sight and touch and muscle-joint sense. However, he is utterly lost under some circumstances in which the man with a normal labyrinth is entirely at ease.

In their search for enlightenment on this subject many noted scientists have done an enormous amount of the most painstaking and delicate surgery, upon birds and animals as well as upon men who had suffered injury.

One surgeon found that the removal of the semicircular canals from a dog very seriously interfered with his muscular co-ordination. In time he appeared to compensate for the loss through the exercise of the other senses and could walk about quite well. He would always fall sprawling, however, if jumping from a height, proving that while in the air and unable to exercise the sense of touch the brain was unable to determine his position with sufficient exactness to adjust his limbs to land in a position of equilibrium.

Many of us have seen a cat while falling turn completely over and alight upon its four feet. At Johns Hopkins University Doctor Muller and Doctor Weed performed a series of most exacting experiments upon cats. It was found that all cats tried would, if held up by the feet and dropped, turn over while falling and alight upon a cushion squarely upon all four feet. It was further found that if blinded by a hood over the head the turning reflex occured with almost the same accuracy, turning to either side, seemingly to be dependent upon the initial position of release. However, the removal of one internal ear destroyed the turning reflex in a majority of the cats while hooded, and those that turned appeared to turn always in the same way, regardless of the initial position of release. If both the semicircular canal systems were removed none of the hooded cats made any attempt to turn while falling, but without the hood would turn properly and alight upon their feet.

Ruggles Orientator—Model 3

Quoting from their report, "From these observations a few conclusions may be drawn. The rotation of cats on falling seems to depend upon excitations derived either from the eyes or from the semicircular canals. Loss of either of these organs of spatial relationship does not interfere with the falling reflex, but deprivation of both these sensory fields abolishes the reflex.

Hence, it may be assumed that the falling reflex is probably an acquired form of protective mechanism, dependent on the influence from the semicircular canals and from the eyes, mediated largely, if not entirely through the cerbral cortex."

Ewald and also Howell reported very careful experimental work upon pigeons. It was found that after the removal of one of the six canals the bird would recover in ten days. And from the removal of two canals would recover in one month, as to walking. The bird was reluctant to fly, however. After all canals were cut away co-ordination was never perfectly recovered and the power of flight was lost. If the pigeon was thrown into the air it dashed wildly about until it crashed upon the earth.

Otologists find that man who has by accident or disease lost one or both semicircular canal systems suffer great derangement of the nervous system and loss of muscular co-ordination.

For a time thereafter any creature so afflicted is a most pitiable object, sprawling helplessly and moving with irregular, misdirected movements, suffering terrible vertigo. Eventually the brain does adjust itself to function without that source of information, but under some circumstances is utterly at a loss, particularly when the senses of touch and sight do not apply or are misleading.

For illustration, a normal man boards a train and notices through the window another train waiting on an adjoining track. Standing, he becomes absorbed in his paper, and presently three subconscious actions take place so quickly he may only analyze them afterward. Through the sense of vision his brain learns that his train is apparently starting, and, in response to long habit, he leans his body forward to preserve equilibrium as the train accelerates. Immediately the labyrinth warns the involuntary brain that the body is beginning to fall, and a foot is shifted to restore the equilibrium. Meanwhile, the voluntary mind, with reasoning power, becomes aroused, and the eyes, searching for additional information, find a stationary pillar which does not change its relative position, but the *other* train is seen to move past the post in the direction opposite that which his vision sense had asserted his own train was starting.

On such occasions, or when walking over uneven surfaces in the dark, a man without the labyrinth will lunge awkwardly or fall, owing to the insufficient knowledge of spatial relationship the brain is able to secure.

These extensive details are enumerated as some of the reasons why the writer was certain a super-development of the labyrinthian sense was most essential to the aviator, for, in the mobile air, his sense of touch with the ship is not entirely reliable, and his vision may be restricted, and from the moment the "ship takes the air" only his brains' ability to

(*Continued on page 787*)

SOME CONSIDERATIONS ON THE DESIGN OF LARGE AEROPLANES

By LESLIE V. SPENCER

NEVER in the history of aviation has the large weight-carrying aeroplane with long-distance flight possibilities been taken more seriously by the general public and the engineering world than at the present time. The trans-Atlantic flight has had much to do with this general interest—an interest which had previously been awakened by the many marvelous things that have been done with the big planes during the war. No doubt the expeditions of the heavily-loaded bombing machines which carried their great weight of bombs far within the German lines opened the eyes of the world to the possibilities of aerial transportation over long distances. We were shown by our own Navy that very long distance flight in heavier-than-air machines is indeed a practical reality when the NC-4 flying boat made its remarkable flight to Europe. That feat answers the doubts of those who have felt that flight across the Atlantic was most foolhardy.

Yet with all the public and technical interest that has been engendered by the London *Daily Mail's* $50,000 trans-Atlantic flight prize offer, and with the attention that other accomplishments of large aeroplanes have gained, it is a rather striking fact that, although some redesign of the standard types of planes has been made in the ships that are being put into shape for the ocean flight attempt, few points radically different from general aeroplane design as we now know it have been incorporated in the planes entered by private concerns for the race. It might be expected that at least several of the entries would have a number of special features incorporated for the express purpose of better meeting the unusual conditions to be encountered in such a long-distance aerial voyage, but in the main one is struck with the conventionality of the ships.

It does not seem to the writer that in most instances enough thought has been given to the engineering side of the matter. In their haste to build ships that will at least possess the germ of long-distance flight ability the navigators and the manufacturers back of them have been content, it seems, to adhere to types of design that have been more or less successful, rather than to strike out along new lines of thought in an endeavor to produce ships primarily intended for the kind of service at hand.

All this is by way of saying that we need more original thought in aeroplane designing. We are not at the stage in heavier-than-air machine development where we can afford to accept present types as being the last word. We must get to work and do some thinking and develop new ideas—discover how to make planes better suited for the special service for which each is intended. Almost any plane will fly if it is given enough power, but now that it is no longer a question of getting the machines to take the air, it is time to start out and *develop* them for each kind of service. The heavy, weight-carrying freight and passenger ship of long-distance ability must not be merely a larger prototype of its smaller brother, which is capable of making a name for itself in the aerial circus.

It is the writer's firm belief that the commercial future of aviation does not lie so much with the small machine of the one- or two-passenger type as with the very large plane capable of real transportation service for the world. When a man wishes to cross the ocean he does not get into a small motor boat and navigate the grim waters himself. Instead, he boards a great liner, where he can have comfort and safety en route.

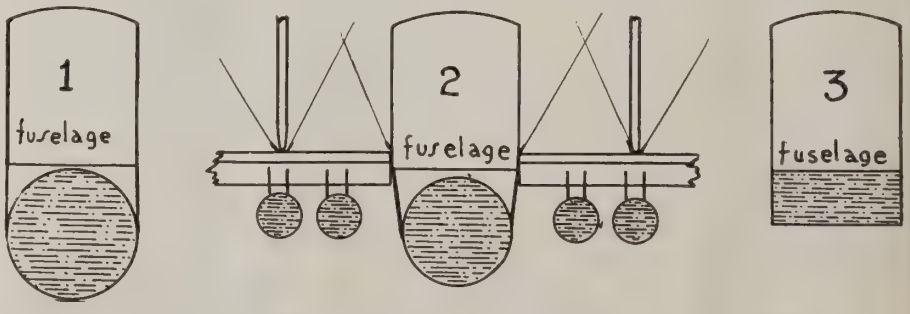
© Int. Film Service

One solution of the problem of fuel carrying. The Short Brothers' plane, which made an attempt at the trans-Atlantic flight, carried a 650-gallon fuel tank under the fuselage

Therefore, let us concentrate more on the large weight-carrying machines which will operate over fixed routes, just as our ships and trains do. Let us leave the small planes for the sportsmen, explorers, the air police and the fighters.

Gasoline Carrying

Perhaps no feature in the design of large aeroplanes for long-distance flight gives the engineer more concern than the method of carrying the fuel. Up to the point where the weight of the fuel overcomes the advantage of a large supply, it is, of course, desirable to carry as great a quantity as possible. For the trans-Atlantic flight, several schemes of tank arrangement have been adopted, and the amount of fuel carried ranges anywhere from 300 gallons up. The Martinsyde machine, for instance, was provided with 360 gallons. The plane has a total weight of 5,000 pounds, and figuring 6 pounds to the gallon, the fuel weight of 2,160 pounds is over 40 per cent of the total. With the Sopwith, the total weight was 6,100 pounds. As this plane carried only 300 gallons of fuel, its gasoline weight was only about 30 per cent of the total. The Navy's NC seaplanes weigh complete about 30,000 pounds, so that, based on the same proportions, they carry anywhere from 1,500 to 2,000 gallons of fuel. These figures serve to indicate the enormous problem which the fuel raises in the design of long-distance machines.



It primarily resolves itself into a question as to where and how to place the tanks so as to take as little of the body space as possible, and so that the gradual consumption of the fuel will not unbalance the ship. It being desirable to concentrate this weight as near as possible to the center of gravity of the machine, the problem is further complicated.

Interesting schemes for carrying the fuel have been worked out. The NC seaplanes have their gasoline tanks disposed around the inside of the body, which means that the fuel must be consumed in such a way that balance will always be maintained. This involves some complication.

On the Short Brothers' trans-Atlantic entry, an unusual tank location was decided upon. Instead of incorporating the reservoirs in the fuselage in some manner, the builders simply suspended a huge tank under the fuselage, as shown in the illustration. The capacity was some 650 gallons, an amount calculated to dispel any fears of the navigators that their flight would not be successful for lack of fuel. The tank measured about 16 feet in length, with a diameter of 3 feet. It is doubtful, however, if such great tank capacity was necessary, especially as the fuel weight seems most excessive, being nearly 4,000 pounds. The ship was not very large, having a wing span of 60 feet and an overall length fore and aft of 35 feet. However, the placing of all the fuel in one tank and the location of the tank are two points in favor of the idea. Roughly, this tank weighs about 600 pounds empty.

The big objection to a tank of this kind in the writer's opinion is the added parasite resistance which it offers. Instead of making it in streamline form so as to reduce the resistance, the builders apparently did not take the trouble. Even if properly streamlined, the location was certainly to be questioned from the resistance standpoint.

Although not reducing the resistance any, the suggested tank arrangement in Fig. 2 would seem to have great possibilities for trans-Atlantic flight. Suppose we support one tank of about 200 gallons under the fuselage, then under each wing hang two or more smaller gasoline drums, after the manner in which bombs are supported in the bombing type of plane. The same type of releasing devices could be employed, and after each tank had given up its fuel, it could be dropped, thus lightening the ship by an appreciable amount. By a system of shut-off valves and universal connections these tanks could be

Three suggested means of carrying a large supply of fuel for long flights

operated so that a tank under each wing would be drained at the same time, allowing both to be released simultaneously, and thereby preserving the balance. This would not be essential, however, as the difference in weight would not be sufficient to have any appreciable effect. The idea would, of course, be to use the fuel in the larger tank under the fuselage last. As a modification of this scheme, Fig. 3 shows how the main tank could be placed inside the fuselage so as to keep the parasite resistance down. Thus, after the wing tanks were dropped, the plane would have no outside encumbrances so far as the gasoline supply is concerned. Still another admirable way of carrying a large supply of fuel would be to have the tanks conform to the bottom shape of the fuselage for a portion of the way back from the engine. This would have the effect of streamlining the tanks into the fuselage assembly, and at the same time an enormous tank capacity would be provided in one reservoir. The plan would not, however, appear to have the advantages of the wing tank scheme, whereby the extra tank weight could be disposed of as soon as it had accomplished its purpose.

Retractable Chassis

While on the subject of parasite resistance, it seems pertinent to bring out the fact that not enough attention has been given to the idea of retractable chassis.

The Sopwith trans-Atlantic machine dropped its landing gear at sea, so as to cut down the resistance. This is getting rid of chassis resistance with a vengeance, but it is going at it in the wrong way. There is no doubt that means for raising the landing gear within the fuselage, or at least within streamlined compartments alongside of the body proper is bound to come, and the wonder is that none of the big planes so far designed have shown any tendency in this direction. It might not be possible to do anything with wheels which lie outside of the vertical planes of the body, but it is not a difficult matter to devise means for raising the wheels and landing gear under the fuselage. This refers to such planes as the Glenn Martin, in which outlying wheels could not easily be taken care of in this way, although the set of wheels further in could be hauled in.

Wheels

Aside from the small added weight of larger landing wheels, there would be distinct advantages to be gained by material increase in their diameter, especially where the retractable wheel idea was inbuilt into the plane. Wheels of larger diameter would not only be stronger, but they would have the important advantage of easier riding over the inevitable rough ground of the average flying field. Each little rut would not transfer as large a shock to the machine as a whole where the wheel was larger and where it did not drop into the rough places so far. Every one knows that the motor car with large wheels rides over rough ground easier than the machine with the small wheels, and it is for exactly the same reasons that attention should be given to this wheel matter for aeroplanes. Where the chassis would be designed to be brought up out of the air stream during protracted flight, it would be just as easy to make room for large diameter wheels as those of the present day small wheels.

Also, by using larger wheels, the chassis struts would not have to be so long as at present to bring the fuselage off the ground the same height as at present. This would result in the strengthening of the landing gear as a whole, since the shorter struts would have greater strength. They would also be lighter, so that when all is said and done, a chassis with large wheels and shorter struts would very likely weigh no more than the present type of landing assembly.

It might be mentioned that the wheels should be located directly below the points of greatest weight. Where the engines are located at either side of the central body or fuselage, it is desirable to have four wheels or sets of wheels: one under each engine position and two supporting the fuselage. This placing of the wheels gives assurance against side tipping when taxying, as well as relieving the structure of excessive strains under landing shocks and when running along the ground. For planes with very long wing span, it might even be desirable to have additional wheels still further out for the same reasons. Of course, many of the well-designed large machines have such wheel arrangements, but there are many instances where this important feature has been overlooked.

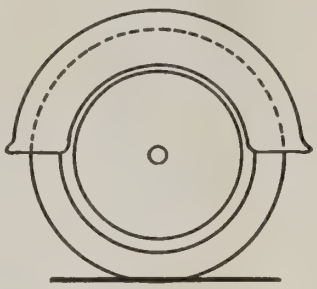


Figure 4—Fenders over the tires are desirable for heavy machines

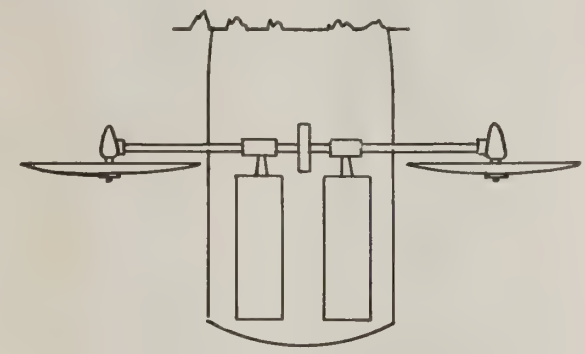

Figure 5—The J. V. Martin scheme for enclosing the engines in the fuselage

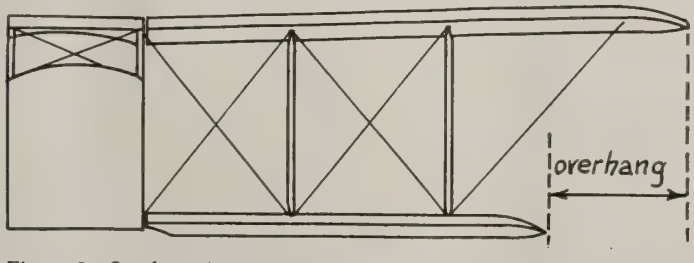

Figure 8—Overhang is not regarded as possessing sufficient advantage to offset the greater structural difficulties incident to its adoption

Mudguards

Mudguards that come down snugly over the wheels are desirable for large machines. Due to the weight, the wheels sink a considerable distance into soft ground, thus picking up more mud than do the tires of lighter planes. The guards are an effective means of scraping this off, if they are properly fitted and so arranged as to catch the mud as it comes around. The mud shields thus play a very important part in preventing damage to the under side of the lower wings, which otherwise would be badly spattered and coated with the wet substance. This causes great damage to the covering of the under side of the wings. In a number of instances where mudguards have not been used, the under wing covering has been punctured by the small stones and dirt, to say nothing of the damage done by the spattering water.

A very efficient type of guard can be designed of somewhat the shape shown in Fig. 4, and should be made preferably of aluminum, either cast or formed out of sheet stock. The metal should be of a thickness sufficient to make a rigid construction free from shaking or wobbling.

Powerplants and Their Location

As regards the methods of powering the present day large aeroplanes, it seems that in the main designers have played the game of following the leader. I do not know who it was that first hit upon the idea of placing the engines out in the wings on either side of the main body portion or nacelle, but it appears that nearly every designer has followed suit. This may or may not be the best way to position the various power units. Certainly it is not the best thing to do from the standpoint of resistance. Building strong superstructures to carry these power units in the wings is a severe structural problem, to say nothing of the great parasite resistance of the multitude of extra struts and braces such construction makes necessary.

There is a great deal to be said in favor of the practice of some designers who have concentrated the power units within the main central part of the plane. The cruiser designed by Capt. James V. Martin is of note in this respect. This ship carries its two engines side by side enclosed within the forward part of the fuselage. A cross shaft back of them leads out on either side to the propeller, a reduction gearing for each screw being provided in a small housing at the transverse engine shaft which connects with the propeller drive mechanism proper. A clutch system within the fuselage makes it possible to drive either or both propellers from one engine or from both engines. Thus it would appear that Capt. Martin

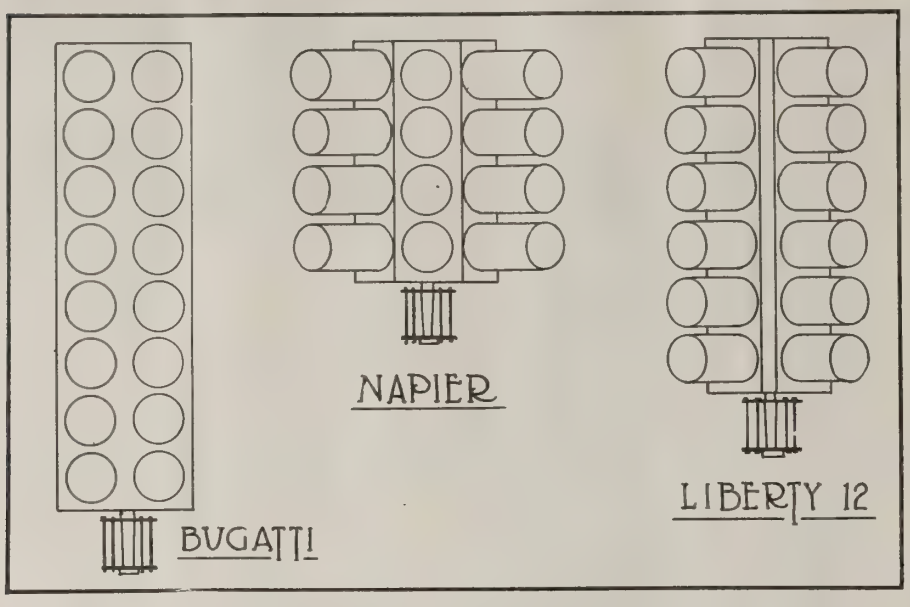

Figure 6—Some of the possible ramifications of present types of power plants

16 cylinders; 2 crankshafts. 2 banks of parallel cylinders

12 cylinders; 1 crankshaft. 3 banks of four 45° between cylinders

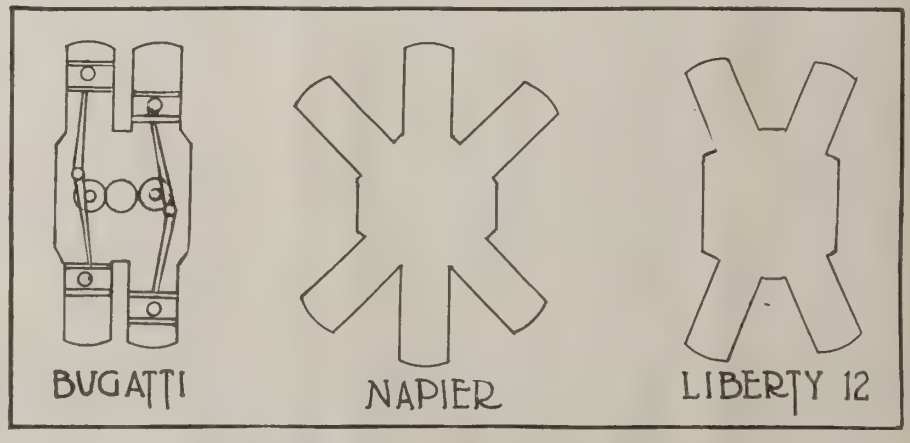
12 cylinders; 1 crankshaft. 2 banks of six cylinders

has all the advantages of the designs where the engines are mounted out in the wings, and at the same time he cuts down the outlying structural work and the resistance materially. The scheme of this ship's driving mechanism is shown diagrammatically in Fig. 5.

In order to centralize the powerplant within the main fuselage, other means are possible besides ranging the several engines side by side. It would not be very difficult to combine any of the present types of fixed cylinder engines by having a common crankshaft for two otherwise distinct powerplants. One set of cylinders would be upside down. In the case of the Liberty 12, for instance, this idea has been experimented with at McCook field with gratifying results. Two upper crankcases were bolted together to enclose the common crankshaft, and the standard connecting rod caps of the upper twelve cylinders were replaced with special caps having bosses to take the rods of the lower cylinders. Thus each bearing was made to carry four rods, and by special arrangement of the oiling, manifolding and water piping the resulting twenty-four cylinder engine was operated. By such an arrangement as this, the power of twenty-four cylinders could be had in little more than the space necessary for a twelve-cylinder engine.

The idea admits of a great deal of ramification. The sixteen-cylinder Bugatti type of engine shown in Fig. 6 could be similarly doubled up to form a thirty-two cylinder unit, as shown in Fig. 7, or the Napier type, in which three banks of four cylinders are employed to make a twelve, two of these could be coupled one above the other in the manner indicated in the diagram, Fig. 7. The thought can also be extended to the radials. The Salmson eighteen-cylinder radial engine might conceivably be greatly enlarged with a minimum of added space by tacking on more banks of nine cylinders each. It is easy to imagine thirty-six or more such radial cylinders being operated on the one central shaft.

By thus concentrating the power, it could be utilized either by running shafting out to the several propellers, or the screws could be placed on either end of the engine shaft with suitable gearing interposed to bring down the rotative speed to efficient values. That is, the concentrated power unit might have a tractor propeller on the front end of its shaft and a pusher to the rear. Clutches could be interposed to cut out either propeller if desired. It has been determined that a single propeller constructed by methods not at all unusual can be designed to absorb over 3,000 horsepower when geared down to somewhat under 1,000 revolutions per minute. This screw would have a diameter of about 21 feet. It would therefore be possible to hold the power of any type of powerplant that could be built up without any trouble. Further, the concentration of power in any such way as suggested would open up the possibility of using one or two large diameter two-blade screws instead of a number of smaller propellers located at various points in the machine as in a number of the present types of planes. Whether or not there would be any advantage to this is an open question, although by employing very large, slow-speed propellers it seems that greater propulsive efficiency would be probable from the aerodynamic standpoint.



The concentration of the power into one doubled-up engine as above outlined is, however, open to the criticism that should anything go wrong the entire unit is out of commission, whereas if several independent units are employed trouble with any one has no effect upon the rest. At the same time, the same thing may be said of any plane having only one powerplant. Besides, by having all the power at one point where it is accessible at all times to the crew, it is possible to remedy slight operative faults, whereas there is no chance of doing anything to a balky unit that is placed out of reach out in the wings. From this angle it seems rather absurd to have engines so placed that they cannot be reached at all when the plane is in the air.

Overhang

The practice of extending the upper wing of a biplane combination out so that it overhangs the lower wing seems to be losing ground (Fig. 8). It should for aerodynamic investigations have indicated that there is not enough advantage to be gained aerodynamically to warrant the added structural difficulties which such a construction introduces as compared with the building of the two wings of the same length. Obviously, a stronger construction can be had where both upper and lower wing tips are in the same vertical plane, eliminating also any wire bracing from the lower end of the outer struts to the tip of the upper wing—a bracing that is almost necessary where the upper wing is given any appreciable overhang.

Conclusions

In these pioneer days of large aeroplane engineering there is utmost need of free thinking and originality of design. We have not come anywhere near the stage yet where we can accept anything as standard or conventional or final. Much is yet to be done before the aerial liner is a reality, and it is the writer's hope that these few remarks and suggestions will at least do their small part in getting aeronautical engineers to thinking along new and original lines—to strike out in new directions so that development will not get into a rut. The design which may appear as a freak to-day may prove to be a revolutionizing factor to-morrow. Aerial navigation has a tremendous future, and what we need now is independent engineering thought and design.

The next steps for the Bugatti, Napier and Liberty types

Combining 2 engines on a common set of shafts to obtain 32 cylinders

24 cylinders by combining two 12's of the Napier type engine

24 cylinders or 32 cylinders by combining two 12 or 16 cylinder engines

The AIRCRAFT TRADE REVIEW

American Handley Page Company Incorporated in New York State

Ogdensburg, N. Y.—A certificate of incorporation for the American Handley Page Company has been granted at the State capital. The company is organized "to establish aeroplane routes within the United States to carry passengers and merchandise."

The new company is capitalized at $5,000,000. The directors are William H. Workman, New York; Harry Clark, Montreal, and Julius Frank, Smith L. Sawley, and Cecil Brownlow, of Ogdensburg.

Mr. William Workman represents the Handley-Page Company of England in the United States. It is not known whether British or American built Handley Page planes will be used on the passenger and express routes to be established by the company.

Aerial Passenger Service Links Chicago With North Shore Section

Chicago, Ill.—An aerial taxi service is to be established by the Chicago Yacht Club.

The plan, as outlined by Charles H. Thorne, commodore of the club, is to operate a line of flying boats between the "exclusive north shore residential section" and the yacht club for members who desire to avoid the necessity of commuting by train and prefer the modern and comfortable flying boat.

Aerial Exhibit for Houston and Galveston

A portable building to house a permanent aeronautic exhibit consisting of aeroplanes, motors, aeroplane guns, bombs, instruments and accessories, is being assembled at Galveston, Texas. Plans for the preparation of a similar exhibit at Houston are being completed.

Champion Spark Plug Salesmen Hold Convention

Toledo, Ohio.—One hundred and twenty-five salesmen from all parts of the United States and Canada have assembled for the semi-annual Sales Convention of the Champion Spark Plug Co. to lay plans for the coming campaign under the direciton of F. B. Coswell, sales manager of the Company.

Landing Field for Chicago and Milwaukee Curtiss Distributor

George Browne, Curtiss distributer for Milwaukee and Chicago, has leased property near the Blue Mound Club, Milwaukee, for an aeroplane landing field. He will establish a passenger-carrying service and also a flying school.

Liberty Fuel to Be Produced in Quantity

Chicago, Ill.—Mayor Zimmerman, who was identified with the development of Liberty fuel during the war, which it was announced some weeks ago, adds ten miles per hour to the speed of aeroplanes and costs $1.00 per gallon to produce, is soon to be placed on the market. Methods of manufacture have been evolved which will reduce the cost of production.

L. J. Martin Buys $10,000,000 Worth of Aeroplane Linen

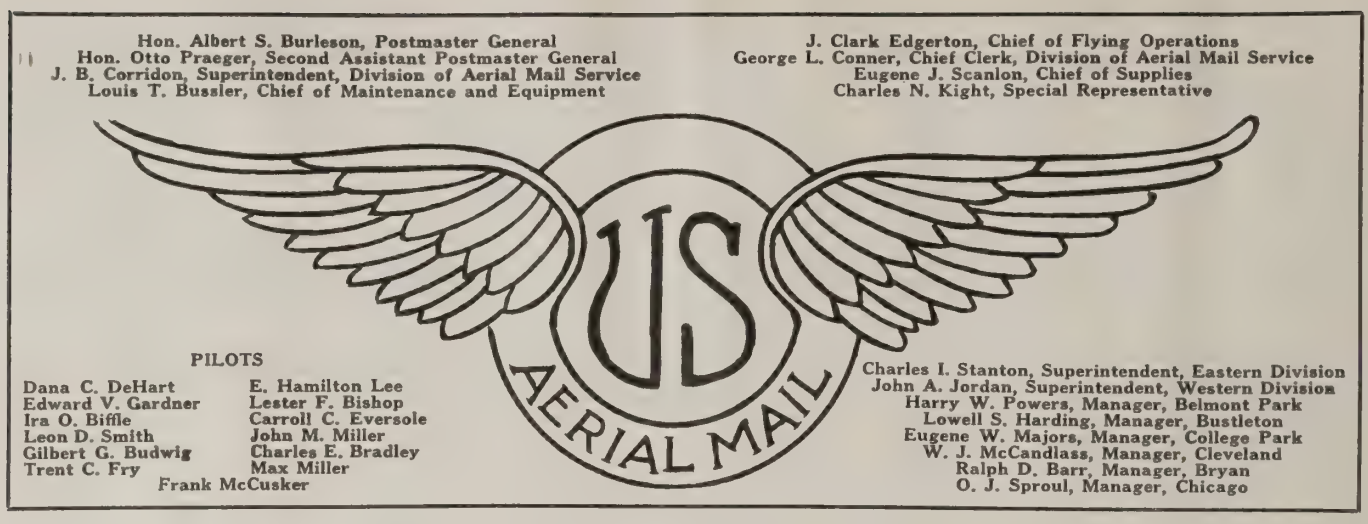
London, England.—A sensational one-man deal was reported recently when, for $10,000,000, the complete stock of linen held by the aircraft equipment section of the Government Disposal Board, about 30,000,000 yards, was sold to Leonard J. Martin, of the London Minories, who paid a check on account and signed a contract made in the first place for covering aeroplane wings.

This great bulk of linen represents roughly three-fifths of a year's output of the Belfast looms.

Curtiss Company Sending Mission to South America

With agencies already established in the Far East, the Scandinavian countries, Australia and Cuba, the Curtiss Aeroplane and Motor Corporation is now planning to extend operations to South America where, at the present time, planes of foreign make hold sway owing to the failure on the part of American builders to cultivate business relationships with our Pan-American neighbors.

On July 1 the Curtiss company will send a mission of expert aviators and mechanics to South America in order to demonstrate American aeroplanes and seaplanes to the officials of the Latin-American governments, corporations and private individuals, and to promote and develop aviation along military and commercial lines.



The mission will be headed by C. W. Webster, supervisor of sales for South America, and among his pilots will be Orten Hoover and Lawrence Leon, two of the best-known pilots in the United States. Hoover has been flying since 1910 and in 1915 he was sent to Brazil to inaugurate aviation for the government. Leon has also had considerable flying experience in the South American countries.

On the same vessel will go the first large shipment of aeroplanes ever sent to the Latin-American countries. The machines that will be taken include the JN-4D land machine, which was used as a training plane by the American and Canadian governments; the new three-passenger Oriole, the world's first commercial aeroplane; the Wasp, a land machine, designed by the Curtiss company as a fighting plane and which, in tests, made a new record of 163 miles an hour and a climbing record of 16,000 feet in ten minutes; the OX-5 motor, used by the government in training planes, and the new Curtiss K-6 and K-12 motors; and the Seagull, the three-passenger flying boat.

Bases will be established throughout South America and the first will be at Buenos Aires and Rio de Janeiro; later bases will be established in Uruguay, Chile, Peru and Paraguay. Demonstrating machines will also be sent to Columbia, Venezuela and Bolivia.

The Curtiss mission to South America. From left to right: Lawrence Leon, C. W. Webster and Orton Hoover

Preparations for New York-Chicago Aerial Mail Route Being Completed

Aviators of the aerial mail division of the Post Office Department are flying daily from Belmont Park out over the route between New York and Chicago, so that when the aerial mail delivery starts they will be familiar with the territory over which they will fly.

The eight hour mail service between New York and Chicago will be in operation by July 1 at the latest, and may be inaugurated some day next week. Mail will be carried in three flights between the two cities. Bellefonte, Pa., and Cleveland, Ohio, are the intermediate stations on the route.

The principal difficulty experienced by the aviators so far is the tendency of the generators of the motors to short circuit in the heavy early morning mists over Long Island. The pilots have gathered in their experimental flights much valuable information concerning prevailing air currents, emergency landing places, etc., which will make their flying easier and safer. A system of landmarks is being established and amplified so that the pilots will not go astray.

It is said that private individuals, confident of the future of commercial aviation, are attempting to obtain Government contracts to carry aerial mail west of Chicago in big three and four motored planes. The Post Office Department is considering their applications.

Extension of Mail Service to Omaha and St. Louis Planned

Aeroplane mail service to Omaha and St. Louis, thus shortening the "business correspondence distance" between the Atlantic and Pacific coasts by sixteen to twenty-four hours, will be in operation by fall, judging from results obtained on the Cleveland-Chicago route, an analysis of which has just been compiled by Second Assistant Postmaster General Otto Praeger, in charge of aerial mail.

Reports show that fifty-eight consecutive trips of 325 miles each have been made between Chicago and Cleveland without delays, without forced landings and without engine trouble of any sort. These flights have been made in weather which, a short time ago, would have been regarded prohibitive. Each day, each way, the "ships" carried 400 pounds of letter mail. As letters range from forty to forty-five to the pound, this means that 16,000 were transported on each trip.

Notwithstanding the inclement weather and the heavy loads, the postal planes—rebuilt De Havilands, equipped with Liberty motors—maintained an average speed of 98.5 miles an hour. On one occasion, when a squall prevailed throughout the lake region, and was so severe as to paralyze shipping in Chicago harbor, the mail plane reached Chicago on time and made a perfect landing on the Postal-Army Field in Grant Park. On another occasion a successful trip was made notwithstanding heavy rains which flooded the field at Bryan, Ohio, to the depth of a foot. On numerous trips fogs, which interfered greatly with both land and water traffic, failed even to delay the air mail. The reason was that engine and plane performed faultlessly, and that the pilot, in addition to knowing his course, was a competent navigator.

Twelve of the De Havilands are in the Cleveland service, four being stationed at each terminal and four at Bryan.

The service shows some interesting time results. Short as this link is, in comparison with a transcontinental line, Pacific Coast mail is even now advanced sixteen hours to Boston and New England points. The reason is that by speeding up a few hours at a vital point, the mail reaches its destination in time for afternoon delivery instead of the following morning. Pacific Coast mail, routed via aeroplane line, is delivered in New York in the morning instead of the afternoon.

Westbound, a similar saving is achieved by taking the mail from the 7 A. M. express at Cleveland, transferring it to the postal plane, and carrying it on to Chicago at almost double the speed of steam transportation.

From now on the mail planes will leave Chicago for the East at 2.30 P. M. It was found that 151 great business concerns sent special messenger mail each noon in an effort to catch the two fast mail trains to the Atlantic seaboard. This meant that much of the correspondence had to be completed the night previous. The 2.30 aeroplane service means that often eight hours to an entire day is saved, and even in the case of the special messenger delivery to the train from two and a half to three hours are saved. Incidentally, the ability of the aerial mail to land at and take off from Grant Park, which is in the heart of Chicago, is further evidence of the need for landing fields within the cities. Then complete advantage is taken of quick transportation offered by the aeroplane.

The mails are constantly growing heavier, and it is a problem to find sufficient rail equipment. Satisfactory operation of the air mail between Cleveland and Chicago has thus been the means of relieving rail congestion, and one distributing car each way each day has been cut from that division. Distribution of aeroplane mail is done in the post offices. This means that $52,000 yearly is saved, while at the same time rail equipment is released for service elsewhere and mail expedited.

The department is able to state that experiments are now being carried on looking toward the delivery and taking aboard of mail bags while the aeroplane is in flight. It is not so many years since it was thought remarkable for a fast steam train to accomplish this feat. It is now regarded as possible for the lightly loaded "ships"—those carrying 1,000 pounds of mail or less—to come close to earth and snatch bags from specially prepared apparatus. In the case of the large multimotored "ships," for which the department shortly will let bids, no attempt will be made to come near the ground, but a scheme is proposed for dropping mail—and possibly taking on—from the roofs of buildings. If this proves practicable it will be possible, on the New York-Washington route, to make non-stop runs, serving both Philadelphia and Baltimore and eliminating fifteen minute stops at each place.

Another interesting development which it is now possible to announce is the construction of fireproof walls between the mail compartment and the engine, and the compartment and the gas tank. A fireproof, airtight bag exactly the size of the compartment will be installed, and within this a second fireproof bag containing the mail pouch. In this manner, tests have demonstrated danger of destruction by fire is practically eliminated.

First Reply to Trans-Atlantic Aerial Mail Received

Washington, D. C.—When Commander Read hopped off at Trepassey Bay for the first successful transatlantic flight in the naval aeroplane NC-4. he took with him a letter from Mr. Harold Braddock, Director of the Savings Division of the Treasury Department to Sir Ribert Kindersley, K.B.E., Chairman of the British National War Savings Committee conveying the greetings of the Savings Division of the United States Treasury Department to those in charge of the British Savings Stamp campaign. According to a press dispatch a reply from Sir Robert has been received, which is said to be the first answer to transatlantic aerial mail.

NAVAL and MILITARY AERONAUTICS

27,000 Miles of Recruiting Flights in One Week

Washington, D. C.—In addition to the thousands of miles of flying at active aviation fields giving instruction to enlisted men, forest patrols and other flights of demonstration in which acrobatics were a feature, the cross-country flying made by the U. S. Army aviators for the week ending June 14th in the interest of recruiting and reported to the Director of Air Service aggregates 27,469 miles.

Board to Select Aerial Coast Defense Sites Along Atlantic

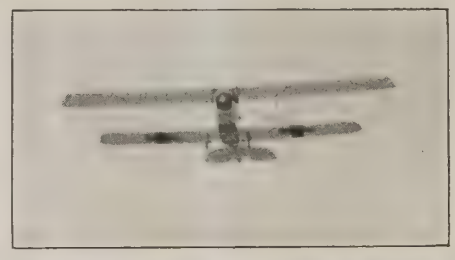
Washington.—In connection with the plan to revise the basic coast defense system of the United States, a board of officers was appointed by the War Department recently to select suitable places along the Atlantic Coast for additional "aerial coast defense sites." Cities to be visited include Portland, Me.; Boston, Newport, New London, New York, Washington and Charleston, S. C.

Twenty De Havilands at Fort Monroe Target Practice

Hampton, Va.—The Seventy-fourth Aero Squadron, demobilized at Mineola on January 14, has been ordered reformed at Langley Field in order to work at the practice manoeuvres of heavy artillery at Fortress Monroe.

Twenty De Havilands will be used.

Dallas-Boston Fliers Have Traveled 2,400 Miles



Indianapolis, Ind.—The Dallas-Boston fliers, Colonel H. B. Claggett, Commanding—five De Havilands—record cross country flying to June 17 2,390 miles in 1,556 minutes, were scheduled to leave for Dayton, Ohio, June 19th, and to arrive in Boston June 20th or 21st, making one stop between Dayton, Ohio, and Boston, either at Buffalo, N. Y., or Schenectady, N. Y., for fuel.

Naval Seaplanes Fly From Gulf to Chicago

Chicago.—Two navy seaplanes completed a trip from New Orleans to Chicago on June 17, when they alighted in Lake Michigan at the foot of East Randolph Street at 10:30 o'clock, completing the final leg of the flight from Peoria, Ill., where unfavorable weather forced an interruption of their flight from St. Louis. The planes were piloted by Lieut. Commander Stanley and Ensign Arthur.

American Aces Now Total 69

The number of American aviators who have downed five or more enemy aeroplanes now totals sixty-nine by the addition of Captain Victor H. Strahm, pilot; Captain Everett R. Cook, pilot; Captain Leonard C. Hammond, observer; First Lieutenant William T. Badham, observer reported from Le Mans, France, under date of May 10, 1919.

Upper view:—The Ellington Field Hospital plane, of which Lieut. Peterson was pilot when not instructor in acrobatics

Lower view:—Lieut. Harold G. Peterson, on duty at Ellington Field since it was opened, is one of the most skilled acrobatic fliers in the service

Lieut. Peterson Ellington Field's Most Daring Acrobatic Flier

Houston, Tex.—Second Lieutenant Harold G. Peterson, who has been on duty at Ellington Field since it was opened up in 1917, is one of the most skilled and daring acrobatic flyers of the Air Service. Lieutenant Peterson is a graduate of the University of Illinois ground school and was sent to Ellington Field as a cadet to help open up the field. For two months after receiving his commission on February 9, 1918, he instructed in acrobatics, following which he was assigned to duty as Hospital Ship pilot.

He was the first man to land an aeroplane on the Boulevard at Galveston. For this purpose the tail skid of ship was wrapped with canvas to help drag tail on slippery brick movement. Boulevard is forty feet across, with low fences and buildings on one side and the sea wall with a twelve-foot rocky drop on other. With a twenty-mile cross-wind, Peterson had to use all his skill in guiding the ship to a straightaway landing in this narrow area. This was the first hospital ship to be landed in the heart of any city and was witnessed by a large number of enthusiastic civilians. Peterson was immediately arrested by the Galveston police for fast and reckless driving of the aeroplane over the Boulevard. Colonel Lawrence W. McIntosh, Ellington's popular Commanding Officer, managed to appease the overzealous "cops" and had Peterson released.

At the Ellington Flying Frolic in April, Lieut. Peterson delighted the crowd of 15,000 with a thrilling exhibition of circling water tower in tight spirals, looping through the clouds, which hung ominously low, 100 feet over the ground, and coming out of loops and tail spins just over the ground. His exhibition prevented postponement and disappointment to the visitors.

Fast Flight From Portland to Sacramento

Lieutenant William R. Beck in a De Haviland 4 made a flight from Portland, Ore., to Sacramento, Cal., 500 miles with one stop at Grenada in 325 minutes' flying time.

In crossing the Sierra Nevada Mountains at an elevation of 12,000 feet, Lieutenant Beck encountered dense clouds, rain and snow.

New York-Seattle Mapping Trip Planned By Air Service

Washington, D. C.—In the interest of recruiting and for the purpose of charting, laying out an aerial mail route and collecting data as to municipal and emergency landing fields, a special transcontinental flight will be organized by the Air Service of the Army to leave Hazelhurst Field, L. I., N. Y., on or about July 6th having as its destination Seattle, Wash.

The tentative route will be across the States of New Jersey, Pennsylvania, Ohio, Indiana, Illinois, Wisconsin, Minnesota, North Dakota, Montana and Idaho. Stops will be made at Philadelphia, Pittsburgh, Columbus, Indianapolis, Chicago, Milwaukee, St. Paul, Minneapolis, Fargo, Bismarck and other points en route. A distance of some 3,200 miles will be covered. The aircraft used will consist of four Curtiss JN-4H planes and Type R Obs. Balloon.

The feature of the trip will be the observation balloon demonstration. This will be transported on trucks and inflated at several of the places where stops are made. The observation balloon will be the Type R used on the front. The motor transport equipment will consist of complete machine shop with all the repairing machinery necessary carried on trucks and lorries. Special attention will be given to photography that when the trip is finished no data will be lacking for the laying out of a perfect aerial lane from New York to Seattle.

The personnel of the party has not yet been decided but it will consist of sixteen officers and thirty-six enlisted men. Eighteen to twenty weeks' time will be devoted to the work and the results determine the route of the return trip.

Air Service Demobilization

Washington, D. C.—According to reports received from the Air Service the net decrease in the total commissioned and enlisted strength from the date of the armistice to June 5 was 80 per cent.

The following table shows the present

distribution of personnel as compared with the figures of November 11 and per cent decrease. The June 5 figures do not include 284 officers and 433 enlisted men on detached service or at demobilization camps awaiting discharge.

	Nov. 11	June 5	Per cent net decrease
Cadets	6,485	187	97
Enlisted men..	170,436	33,461	80
Officers	20,852	4,946	76
Total	197,771	38,594	80

During the week ended June 5, 1919, the decrease in the Air Service personnel overseas was 626 as against a weekly average of 3,083 for the past month.

The strength of the Air Service in the U. S. and overseas on November 11, January 30 and June 5 is shown in the following table:

	U. S.	Overseas
Nov. 11.....	119,882	77,889
Jan. 30.....	46,919	57,527
June 5.....	15,249	23,345

General Menoher At Airnaut Club of Washington

Washington, D. C.—Major-General C. T. Menoher, Director of the Air Service, was the chief speaker at the meeting of the Airnaut Club of Washington at the June 2 meeting. Lieut.-Col. S. C. Clark presided.

Mr. M. W. Perley was elected President of the club. Other officers chosen were: First vice-president, Mrs. Catherine E. Warren; second vice-president, Miss Anna P. Ross; secretary, Louis E. Florey; treasurer, Albert Lariviere; to the board of governors, Mrs. Eleanor Belyea, Capt. H. C. Sigourney, Miss Rosly Carli and S. N. Bernhardt.

Captain N. B. Hall, U. S. Coast Guard officer in charge of inspection of all navy power plants and planes for the Brooklyn Aeronautic District, comprising New Jersey, Southern New York and Connecticut

Special Orders Nos. 135 to 139, Inclusive

Capt. Byron H. Mills will proceed to Kelly Field, San Antonio, Tex.

Lieut. Col. Davenport Johnson, Jr., will proceed to Chicago, Ill., on temporary duty for the purpose of conference with the department Air Service officer, Central Department; thence to Selfridge Field, Mount Clemens, Mich., take station, assume command.

Capt. Charles W. Drew will proceed to Selfridge Field, Mount Clemens, Mich, and report upon arrival to the commanding officer for duty with the first pursuit group at Selfridge Field.

First Lieut. John W. Frewer will proceed to Hazelhurst Field, Mineola, Long Island, N. Y.

First Lieut. James G. Hall will proceed to the United States Naval Air Station, San Diago, Cal.

Second Lieut. Charles M. Potter will proceed to Langley Field, Hampton, Va.

Second Lieut. Mark H. Redman will proceed to Dayton, Ohio, and report upon arrival to the chief Engineering Division, Air Service.

Second Lieut. John Earle Brown will proceed accompanied by the necessary attendant to General Hospital No. 1, New York City, and report in person to the commanding officer, that hospital, for further treatment.

First Lieut. Junius H. Evans, Air Service, is attached to the Motor Transport Corps, and when he can be released from his present duties will report in person to the commanding general port of embarkation, Hoboken, N. J., for assignment to duty with the motor transport officer, 461 Eighth Avenue, New York City.

Second Lieut. James Roy Barker will proceed to Fort Snelling, Minn., and report to U. S. A. General Hospital No. 29 for duty.

The following-named officers will proceed to Kelly Field, San Antonio, Tex.: Capt. Robert V. Gallagher, First Lieuts. Parker V. Ahl, Morris Berman, Second Lieuts. Cecil E. Archer, J. Harold Carroll.

(*Continued on page* 788)

TRANS-ATLANTIC FLIGHT PLANS

R-34 Ready to Start on Trans-Atlantic Flight

London.—The British dirigible R-34 is ready to start on the trans-Atlantic flight. She arrived on June 20 at East Fortune, Scotland, after a 56-hour test flight, which took her into the Baltic for the twofold purpose of learning whether there was any unusual activity in German shipping and to further test the machine before attempting to fly across the Atlantic.

The giant machine had a rough trip, and it is unlikely that she can be ready to start for America under ten days, the earliest estimates being a week. Just how far she proceeded up the Baltic it is impossible to learn, as the Government has cautioned the officers and crew against saying anything with regard to the trip. It is learned, however, that the ship went abreast of Berlin, just outside the three-mile limit.

The airship battled against a strong westerly wind during 20 hours of the homeward journey. Colonel Hunt, commanding the station here, has suggested to the Air Ministry that the flight across the Atlantic be postponed for a fortnight. It is estimated that the total round trip of the Baltic totaled 1,200 miles.

The R-34 will not not fly to the United States as planned until the German decision to sign or reject the peace terms is made. If the Germans reject the allied terms her cruise may be eastward on a less friendly mission than her visit to America.

No official word, however, that the flight of the big British dirigible R-34 to this country has been postponed has reached Lieut.-Col. Frederick W. Lucas, R. A. F., who is in this country to prepare for her coming

Special wireless communications regarding weather conditions are now being sent out to aid the pilots of the big dirigible in planning their voyage. The messages will be extended as soon as the start is made and the information sent in much greater detail. Regular signals will be sent out to assist in guiding the air voyagers from wireless stations at Bar Harbor, Boston, Newport, New York and Cape May. At Roosevelt Field another radio station is to be set up to communicate between the ship and the ground while the landing is being made.

Handley Page Waiting for Good Weather at Harbor Grace

Harbor Grace, N. F.—With all preparations and tests completed, the four-motored Handley Page is still waiting for favorable weather. Despite their eagerness to get away, however, it is by no means certain that they will depart at once, as they are determined to await an ideal wind, since otherwise the task they have set themselves of beating the Vimy's distance record is hopeless. Admiral Kerr and the other fliers are particularly anxious to depart for fear that there may be some change in the plans ordered by headquarters.

Major Geoffrey I. Taylor, meteorological officer of the expedition, is in St. John's, camping close beside Lieutenant Lawrence L. Clemens, the Air Ministry meteorological officer, to whom come all official weather reports. Major Taylor will flash word here the moment he decides conditions are suitable for departure.

The Alliance Aeroplane Company, Limited, of England, which had completed all preparations for sending its biplane Seabird to Newfoundland to attempt the ocean crossing, has canceled all arrangements and withdrawn its entry. Word of this was received from the firm by its advance representative, Lieutenant Williams, at St. John's recently.

Plans of the Boulton and Paul Company to start two fast planes to Ireland have been abandoned, according to a cable message received here by Major Fiske, the representative at St. John's of the British firm.

Alcock and Brown Given Knighthood in Order of British Empire

London.—When Captain Alcock and Lieutenant Brown received, at the hands of War Secretary Churchill, not only the *Daily Mail's* $50,000 prize at the *Mail's* luncheon in their honor on June 20th, but knighthood in the Order of the British Empire, bestowed by the King, there had ensued, unknown to hundreds present, a little dialogue between Brown and American Ambassador Davis.

Brown wanted to know if he would jeopardize his American citizenship by accepting knighthood. The Ambassador relieved his mind by telling him that as a private citizen he had every right to accept it. So Brown becomes Sir Whitten Brown, and the Vickers-Vimy pilot Sir J. Alcock.

Besides the *Daily Mail* prize, the airmen received $10,500 from a cigarette company here and $5,000 from another source. In his speech Brown said they decided before leaving St. John's to invest the money in the British Joy Loan.

Brown intends, after his marriage to Miss Kennedy, early in July, to return to America.

FOREIGN NEWS

Entries for Australia-England Competition Received

Mr. Bert Hinkler is the first airman to enter for the Australian Government's $50,000 prize for a flight from Great Britain to Australia (15,000 miles in 720 hours). He will fly a Sopwith "Dove" biplane with 80 h.p. Le Rhone engine, and he is rapidly completing his arrangements at the Sopwith Aviation Co.'s works, Kingston-on-Thames. The second entry for the flight was made at the Royal Aero Club on Saturday by Lieutenant C. E. Kingsford-Smith, M. C., on behalf of himself and two companions, Lieutenant V. Rendle and Lieutenant Cyril B. Maddocks, all Australians. The Blackburn Aeroplane Co. has provided the machine, a Blackburn Kangaroo, with two Rolls-Royce Falcon No. 2 engines, each of 255 h.p.

London-Birmingham Passenger Service

The first passenger aeroplane from London to Birmingham landed at Bromwich Castle last week. It was a Handley Page machine, piloted by Colonel W. S. Douglas. Leaving Cricklewood at 5:30, the aeroplane arrived at Birmingham at 8:45, having dropped parcels of London newspapers at Nottingham and Northampton en route. Lord Belper was one of the passengers.

Parseval Building 75-Passenger Dirigible

It is announced from Bitterfield that the Parseval Works have almost completed the construction of a giant airship, capable of carrying 75 people. It will be used for crossing the Atlantic.

Book Proofs by Aeroplane Save Publisher Two Months

Mr. Patrick Thompson is publishing *Cocktails* (a collection of tales on aeronautics) through Collins & Sons. The proofs of the book, consigned to the ordinary land and sea mail service on March 7th, took nearly two months to reach him. After correction the proofs were entrusted to some friends from 110 Squadron on their way back from the R. A. F. Sports Tournament at Vron. The packet was taken to the halfway aerodrome on the Folkestone-Cologne air mail route and handed to the first home-going pilot. The packet left at 11:30 a.m. and was in the publishers' hands that night.

Winston Churchill is Taking Flying Lessons

Mr. Winston Churchill has resumed his flying lessons, which were interrupted at the beginning of the war. He is going through his course at Hounslow on an Avro machine in charge of an R. A. F. instructor.

Netherlands Government Purchasing Planes for Java and East Indies

The Netherlands East Indian government is considering the purchase of twenty aeroplanes of the bombing type for operation between Japan and the islands it owns in the Far East. Although intended for commercial use, it is planned to have the aeroplanes for military reasons should the occasion arise.

British Columbia Mining Company to Use Aeroplane Transport

The Queens Mines, Inc., of Nelson, B. C., are negotiating for the purchase of aeroplanes to operate between their Nuget Mine, on top of a mountain, and the coast, fifteen miles away.

Brussels Gets Live Lobster from Paris by Aeroplane

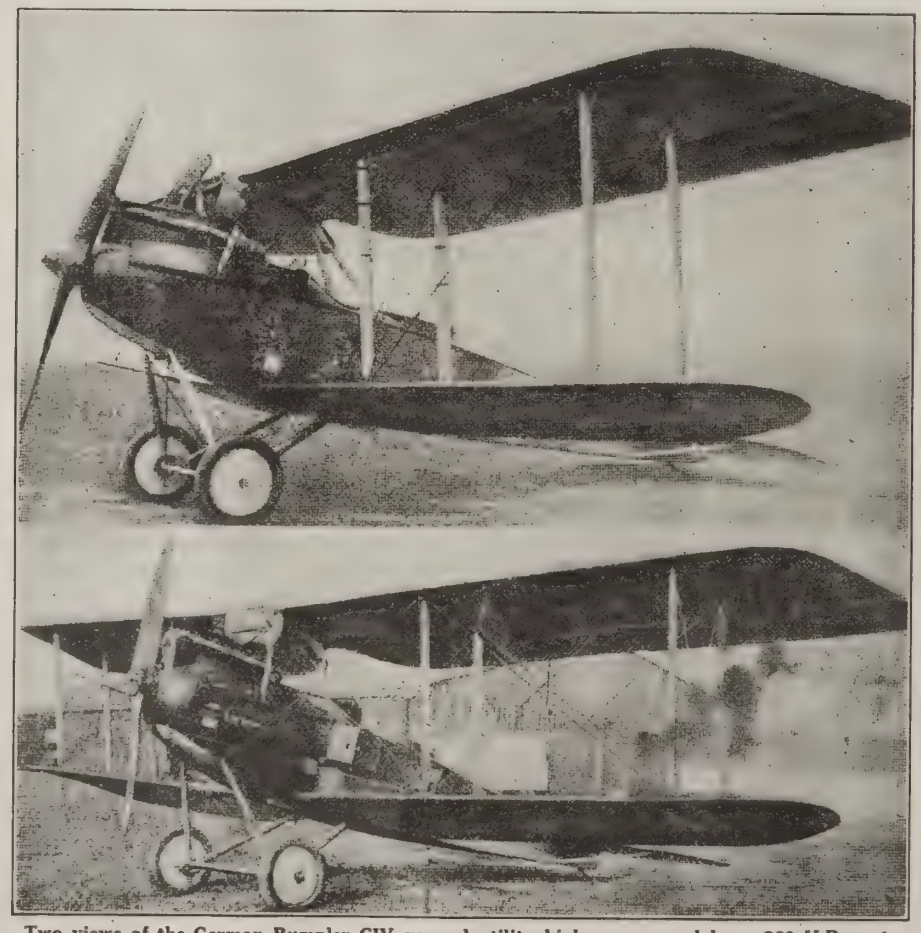
Brussels.—Regular transportation of merchandise by aeroplane between Brussels and Paris, established by companies in the two cities, has already resulted in some unusual cargoes being carried. For instance, a consignment of nearly 500 pounds of live lobsters was brought to Brussels by one of the aeroplanes of the system. The lobsters were in excellent condition.

Aerial Service for Brazil

Under the terms of a Brazilian government decree, as published in the "Diario Oficial" of Rio de Janeiro, J. B. dos Santos and A. de Araujo Goes are empowered to establish an aerial service, without privilege or monopoly, for the transport of passengers and mails between the principal cities of the country and the intermediate towns. Two years are allowed for the establishment of the service, but an extension of time may be granted. The service is intended principally for passengers and goods, but the concessionaires are obliged to carry mails. The timetable and fares will be fixed with the approval of the government, and will be revised every three years.

31 British Companies Are Now in Aeroplane Insurance Combine

London.—Thirty-one British insurance companies are now in the aviation accident and liability insurance combine which has pooled liabilities and premiums.



English Hotel to Have Air Service

It is stated that the Birkdale Palace Hotel will shortly begin a private air service. Guests from the Isle of Man or Blackpool who wish to travel by air will be waited upon by hotel aeroplanes. This is believed to be the first hotel air service in Europe.

Thos. Cook and Co. Arranges Aerial Tours

Evidence that the commercial development of the aeroplane is proceeding by leaps and bounds is indicated by an advertisement inserted by Thomas Cook & Sons, tourist agents, in the London Times during the Easter holidays.

The agency advertised aeroplane pleasure trips over Cricklewood, near London, on Easter Monday. More than a thousand men, women and children availed themselves of the opportunity and for two guineas each had a half hour flight over Cricklewood. Handley Page machines were used in the flights.

Two views of the German Rumpler CIV general utility biplane, powered by a 260 H.P. motor

Shanghai-Pekin Passenger Service Being Arranged by Pekin Syndicate

The Pekin Syndicate, Ltd., has recently purchased several Handley Pages to operate a line between Shanghai and Pekin, a distance of 700 miles. A fast passenger and mail service will be established.

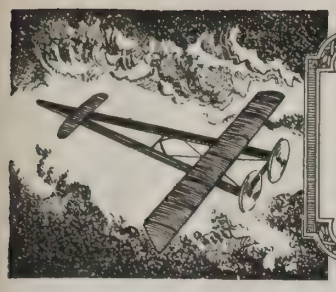
Casale Again Sets New Altitude Record

Villacoublay.—Adjutant Casale, the French aviator who established a new world altitude record of 31,168 feet recently, broke his own record on June 14 by ascending in his aeroplane to a height of 10,100 metres (approximately 33,136 feet).

The flight was made in fifty-five minutes. The temperature at the high point was eight degrees below zero.

All Air Force Planes Required to Have Parachutes

London.—Compulsory fitting of life-saving parachutes to all aeroplanes of the Royal Air Force has been decided upon by the government. Whether this will be applicable also to commercial aircraft has not yet been settled.



Catches Aquitania by Aeroplane

London.—After missing boat and train to Southampton on June 14 for the Cunard liner Aquitania, Mrs. Leon Errol adopted the novel method of flying by aeroplane to the port of embarkation.

She obtained an aeroplane at Hounslow, from where ascent was made. After a flight of an hour and fifteen minutes the machine descended five miles from Southampton, where she was met by the captain of the ship, who motored her to the docks, catching the boat.

Parachute and Collapsible Boat to Make Over-Water Flying Safer

Rome.—The trial of a new parachute was carried out on May 9 over the sea off the port of Anzio. The parachute, with Lieut. Emerson, an American officer, who was also provided with special collapsible pneumatic boat, was safely launched. Lieut. Emerson alighted on the water from a height of 420 metres, and then got into the boat.

Prizes for Aerial Age Contests

THE accompanying cut shows a reproduction of the prizes which AERIAL AGE is offering for the Model Contests which are now going on throughout the country. Hundreds of model flyers are striving to win the cup and the medals.

The cup is a work of art and, with the inscription engraved on the front, makes a very appropriate prize for the best construction model. It was intended at first to offer a bronze cup with silver trimming, but this was later changed to one of silver with a gold lining. This cup is the goal to which many experienced model builders are working, and from the photographs and descriptions received by this department, the winning model will be a work of art. Some of the scale models of which details have been received can fly, and, of course, this will be a point in their favor when the winner is declared. The way the winner is decided is very fair. Should a good scale mode be capable of making short flights, it would, of course, be declared better than the one that did not fly. Then, on the other hand, if an exceptionally well-constructed and designed model should come along, it would be given preference over one that could fly.

The medals on each side of the cup are very well designed, as the reader can see at a glance. Any one of these medals would make a watch fob, if the winner should not care to use it as it is. A full list of the winners will appear in the first available issue of the July numbers, as well as photographs and specifications of the machines.

It is requested that all those who have not as yet sent in their reports of flights do so without further delay, as it takes time to judge the qualities of the models. If you should send them early, the winner could be declared without waiting until the summer is too far gone.

The beautiful prizes shown above were made and designed by the Arthur Johnson Company. These people are the originators of aeroplane jewelry and they have turned out the best workmanship possible to create the medals and trophy for the Aerial Age winners

Light Flying Boat

With the next issue is started a design of a two-seater flying boat of low horse power and very light weight. Since the Ford Motored Aeroplane was described on this page some months ago, the writer has been asked by numerous flying enthusiasts to tell through these articles whether the Ford Motored Aeroplane could be fitted with pontoons. We did not endeavor to answer this question at that time because tests were being made with one of these machines to determine the reserve lifting power, and until these tests were completed nothing could be determined.

We have since found that the Ford develops much more horsepower at the propeller than was first supposed, and we do not hesitate to say that the machine was was described on this page can be made to rise from the water with lightweight pontoons. We can be closer in our figures for the flying boat now that we know exactly what power the Ford will develop.

In order to get sufficient power from the Ford, it is necessary to have it running at about 2,000 R.P.M. with propeller of 6 foot diameter and pitch of about 32 inches, when connected direct, or to have the propeller geared down, that is, to have the engine running fast and the propeller running at half speed. This combination gives more horsepower, and a propeller of 7 foot diameter with 4½ foot pitch can be used instead. This will give us enough pushing power for the flying boat to be described later.

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

The Vikings of the Air

Like Norsemen bold who launched their sturdy craft
On seas that stretched beyond their furthest ken,
And drank deep draughts of ocean's briny air
With keen delight, and sailed they knew not where,
So stand ye at the Atlantic's mist-bound shore,
Ready to leap into the buoyant air—
Ready to span, with wings outstretched on high,
The ocean turbulent, 'neath the wind-swept sky.

Knights of the air, on high adventure bound,
Our hearts with yours in unison do beat.
Faint not nor fear to risk the uncharted way
And taste the glories of the risen day.
Like you, we, too, into the unknown launch!
Each morn a misty vista doth unfold;
Dark clouds above and ocean waves affright,
But all our paths are in the Pilot's sight.

—*Josephine M. Fabricant* in the *New York Times.*

Has your left shoe one of these new aeroplane tongues? One that has a tendency to sidestep?—*E. L.*

In "Civies"

Where are the girls who used to smile,
  And the rides I used to get,
And where is the crowd that was very proud
  To pass me a cigarette?
Time was I danced with maidens fair
  And captured their hearts by storm,
But I've lost my pull with the beautiful
  Since quitting the uniform.

I've sunk my shoes into Turkish rugs
  That only the rich can own;
At tables fine I've been asked to dine,
  In the heart of the social zone.
In the cushions deep of a limousine
  I have rested my manly form,
But I've lost my graft with the tony craft
  Since quitting the uniform.

I've been a king on the ballroom floor,
  An ace in the social whirl;
I could show my face in any old place,
  And never a lip would curl.
I could walk right up to a rich man's door,
  And be sure of a welcome warm;
But I've changed a lot, and they know me not
  Since quitting the uniform.

Now I walk down town and the autos pass,
  And nobody says "get in!"
And the girls are shy when I'm standing by
  And they give me the tilted chin.
And nobody knows and nobody cares
  Whether I eat or how;
I must buy my own chuck, for I'm out of luck—
  I'm wearing the "civvies" now.

—*Edgar A. Quest* in *Rockwell Field Flight.*

The Atlantic Flight

As the fledgling from the nest
  Flutters forth to meet the wind;
As the traveller trekking West
  Hurries on with gladsome mind
Over burning sands uncrossed;
As the sailor, tempest tossed,
  Eager-eyed for countries new;
So they scan the ocean grey,
  Watch the clouds that scamper by—
Hopeful for propitious day
  On their pinions frail to fly.
Youth is glorious and bold,
And the New World with the Old
  Will be hand-clasped by their might.

—*W. L. A.* in *Aircraft.*

Solution of a Pressing Problem

Wifey: "Darling, I've lovely news for you. I engaged a servant yesterday, and she's just arrived."

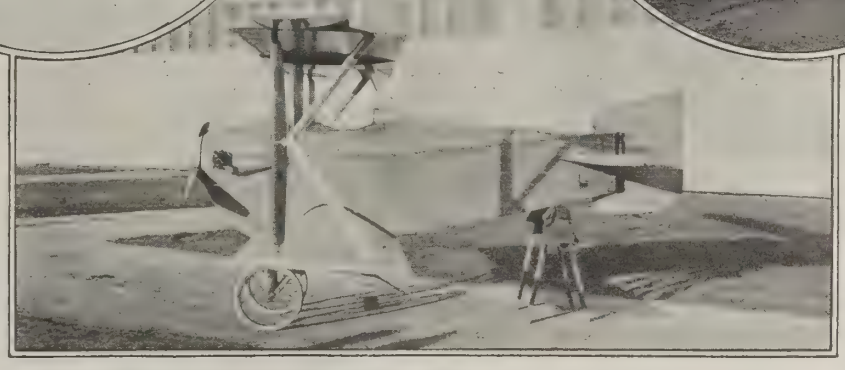
Hubby: "You priceless old thing. Hope we'll be able to keep her."

Wifey: "Oh, I hope so. Suppose, darling, you go down to the hangar, and do something to the engine of her 'plane. Then she'll have to stay a week at least."—*Aircraft.*

That young aviator who called on Sis that terribly hot evening made himself good and solid with the rest of the family

—By Fontaine Fox in the N. Y. "Globe"

EVERY FIRST CLASS AEROPLANE REQUIRES A RETRACTABLE CHASSIS



The World's Most Efficient Light Scout MARTIN KIII

Chassis Retracted

First Shock Absorbing Rudder

First Retractable Chassis

No other light scout of low horsepower can even approximate the performance of the K 3 for the following reasons:

1—The Retractable Chassis, protected by both basic and improvement patents for any shape, or method of retracting, eliminates 17% of the useless or parasite resistance.

2—The K-bar Truss, acknowledged by the British Air Board to be the only rigid single lift truss, eliminates half of the useless or parasite cellule resistance.

3—The Martin form of wing end, proved both in America and Europe, the most efficient shape.

4—The Shockabsorbing Rudder which simplifies rudder bracing and control, provides exceptional taxing manoeuverability and eliminates the Parasite resistance of the usual tail skid.

5—The Wing end Aileron, proved by actual tests in full flight to be four times as efficient as the trailing edge aileron, leaves the K 3 wing aerofoil unimpaired.

6—The structure of the K 3 has a **tested safety factor of eight** and weighs complete with motor only 350 lbs. (Compare this with the weight of other 40 h.p. scouts.)

Exclusive manufacturing rights for a similar commercial plane designed around a reliable 40 h.p. American motor for sale for 5% of the gross sales.

CAPT. JAMES V. MARTIN, U. S. Master Mariner and pioneer aeroplane builder who originated and demonstrated in 1911 the modern tractor biplane in all its essential features, such as interconnected trailing edge ailerons, tail decalage and a modern type fuselage with clamp longeron fittings.

All the Martin devices are freely at the disposal of the U. S. War Department and can be used on reasonable terms by other constructors.

(*Continued from page 773*)
correctly determine spatial relationship and direct calm, precisely co-ordinated muscular action, prevents his return to earth in a splintering crash.

That this faculty is capable of extensive development is proven daily. The rubber tires of the bicycle have no nerves, yet the trick bicycle rider performs wonderful feats in equilibration by the aid of this little organism.

Wonderful and infallable as this labyrinth appears, however, the student of this subject locates in some of its peculiarities the cause of many an aviator's fatal crash. It senses rotation with remarkable accuracy, but if the rotation exceeds the degree to which the individual is accustomed and then stopped, it continues to "register" rotation—but in the opposite direction. This is a false impression, for the person is motionless, and on the earth is usually detected by the sense of touch, which is less effective in the sky, for the ship has a free rotational possibility.

Further, the vision is so closely associated with the semicircular canals that when this false rotational sensation is felt objects before the eyes appear to be rushing past at the same rate of speed, though the man and the objects are both perfectly stationary. This continues and diminishes to the vanishing point only when the motion of the lymph in the canals and the displaced nerve ends have resumed their position of rest.

If a man be whirled in one plane of rotation rapidly and then tilted into a different plane and held motionless, he feels this false rotational sensation, with its accompanying visual effect, but in the latter position. That is, the effect is felt in the plane in which the canals are held that have endured the excitation regardless the first position.

This phenomenon affects the aviator in various ways. In the fast tail spin the lateral canals are in the horizontal plane and accumulate rotational sensation. Coming out of the spin, though the ship be brought out perfectly level, the student aviator will feel that false rotational sensation, for the lateral canals have brought it with them from the spinning position, and as though verifying it for true, the eyes are affected to such an extent that the horizon appears to tip up at an acute angle. This sensation may be interpreted by the experienced pilot, but the beginner has a tendency, in trying to keep the ship level, to go into a side slip and another spin in the opposite direction, which sometimes continues to a crash.

Another peculiarity of this organ appears in the variations to which it is subject. Its dependability is affected by worry, illness, or exhaustion.

Also the man that becomes entirely familiar with certain rate of spins or turns, by exceeding the rate of angular velocity or the number of turns he makes in spinning may find the same confusion, for while a slower motion does not confuse, a rate faster than he is accustomed to, confuses.

We know that fancy ice skaters, spinning dancers, and other trick performers by practice endure extraordinary gyrations without confusion. Our first acrobatic flyer of note is reported to have been a circus performer before becoming an aviator.

The writer believed these faculties of vital importance in piloting an aeroplane capable of almost limitless development and training, if it might be conveniently continued to proficiency without apprehension or accident. And that when so developed and trained the student-aviator could be taught the art of managing a ship in the sky with the minimum of danger to his instructor and to himself, and the maximum of comfort and dexterity in future flying.

Inventing an apparatus that might provide the student-aviator the rotational possibilities of the plane in the air, and at the same time the facilities for developing the so essential muscular co-ordination without the likelihood of injury to himself or his assistants was not an immediate accomplishment. Almost endless were the plans considered, improved, and discarded. Persuading men of position to believe in the idea or the invention was even more difficult. The average aviator of a few years ago did not believe he had a static labyrinth, and the average hard-headed business man was not interested in sixth-sense problems, and was inclined to doubt the possibility of the machine operating as predicted, or producing the effect if it did.

The Ruggles Orientator, Model 1, was completed under the auspices of the Naval Consulting Board. It immediately demonstrated the soundness of the inventor's contentions. This was followed by Model 2, and then by Model 3, which has been made standard for the United States Army Air Service.

The faculty of orientation varies in individuals quite as much as other faculties. Also the ability to co-ordinate quickly, but smoothly, the muscular actions that will guide the ship. This is strikingly demonstrated by the students working in the Ruggles machine.

The beginner who is confused by the unusual position and who "freezes" or jams his controls, or cannot time his muscular actions to the positions or evolution he tries for, or becomes dizzy after a quick turn, with a little careful attention of the instructor quickly overcomes all these

difficulties and improves with surprising rapidity in manoeuvering blindfolded through predetermined evolutions. Soon his spatial relationship senses become so accustomed to the unusual positions that the dangerous involuntary, unintelligent muscular movements give place to calm and intelligently directed actions, and the interference of the instructor's dual control is met with intuitive correction. The false turning sensations that follow rapid manoeuvers are interpreted and involuntarily compensated for. The tendency to dizziness diminishes.

The direction of men's bodily activities may be compared to the navigation of a steamship. The commander decides upon the course, speed, etc., and gives instructions to the Officer of the Watch, who will, in event of unfamiliar danger, consult the Commander for more authoritative decision. It is of the utmost importance, however, that he be a thorough seaman, for when a trusted lookout calls warning of a danger so imminent that the Commander may not be consulted disaster is averted by his soundness of judgment and immediate action.

Man's voluntary (reasoning) brain is the commander of the body. The involuntary brain is the "officer of the watch"—that takes charge while the commander is otherwise occupied. The most favored lookout is the always active static labyrinth. To the man who pilots an aeroplane it is of supreme importance that this combination of officer and "lookout" be trained to a calm and correct appreciation of as many situations as possible.

The Ruggles Orientator, calling into action some of the most vital functions of life, with its many special attachments, affords opportunities to the otologist, the physiologist, and the psychologist, and also to the merely practical student-aviators.

(*Continued from page* 781)

The following-named officers will proceed to Rockwell Field, San Diego, Cal., and report in person to the commanding officer for assignment to duty with the 2d Aero Squadron: First Lieut. Ross F. Cole, Second Lieuts. Charles A. Batty, John Blaney, William E. Olssen, Jr., First Lieut. Sidney P. Le Boutillier, Second Lieuts. Charles McK. Robinson, Hjalmar F. Carlson, John J. Curtis, Jerry L Bennett, Elbert W. Franklin, Raymond P. Birdsall.

The following-named officers will proceed to Hazelhurst Field, Mineola, Long Island, N. Y., and report for assignment to duty with the 3d Aero Squadron: First Lieut. Richard J. Kirkpatrick, Second Lieuts. Mark R. Woodward, Philip H. Downes, First Lieut. Clarence L. Midcap, Second Lieuts. Kenneth Garrett, William C. Maxwell, First Lieut. Leo Fred Post.

The following-named officers will proceed to Wichita Falls, Tex., Call Field: Second Lieuts. Robert T. Gallagher, William B. Atwell.

The following-named officers will proceed to Detroit, Mich., reporting upon arrival to the commanding officer Aviation General Supply Depot for discharge under the provisions of Circular No. 75, War Department, 1918: Capt. William F. Long, First Lieut. Rossiter H. Kellogg, Second Lieut. Robert H. Carson.

Major George E. Lovell, Jr., Air Service, is detailed as a member of a board of officers appointed in paragraph 83, Special Orders, No. 135-O, June 10, 1919, War Department, vice Major Albert D. Smith, Air Service, hereby relieved.

First Lieut. George M. Palmer will proceed from Ellington Field, Houston, Tex., to the aviation repair depot, Speedway, Indianapolis, Ind.; thence, by aeroplane, to Bolling Field, Anacostia, D. C.; thence, by aeroplane, to Langley Field, Hampton, Va., on temporary duty in connection with the Air Service of the Army, and upon completion of the duty enjoined will return to his proper station, Ellington Field, Houston, Tex. The purpose of the travel is to fly a Handley Page aeroplane to Langley Field, Hampton, Va., and the stop at Bolling Field is for the purpose of receiving several cameras.

First Lieut. Clarence G. McCarn will proceed from Kelly Field, San Antonio, Tex., to Rockwell Field, San Diego, Cal., and will report upon arrival to the commanding officer for assignment to duty with the 2d Aero Squadron.

First Lieut. James B. Wallace will proceed to Fort Monroe, Va.

By direction of the President, Capt. William E. Scarboro is dropped from the rolls of the Army under the provisions of section 1229, Revised Statutes.

Capt. Frank A. Llewellyn is transferred to Garden City, Long Island, N. Y., and will report to the Air Service depot for duty.

First Lieut. Harry M. Carroll will proceed to Selfridge Field, Mount Clemens, Mich.

The following-named officers will proceed to Call Field, Wichita, Tex., and report in person to the commanding officer for duty: Second Lieuts. George H. Beverly, Paul H. Prentiss.

Second Lieut. George A. Clark will proceed to Washington and report in person to the Director of Purchase, Storage and Traffic for assignment to duty in the office of the Director of Finance.

First Lieut. Clifford G. Sample is announced as on duty requiring him to participate regularly and frequently in aerial flights from April 30, 1919.

Second Lieut. Rowan A. Greer will proceed to Rockwell Field, San Diego, Cal.

First Lieut. Joseph R. Pearson, Jr., will proceed to Dayton, Ohio, and report in person to the Chief Engineering Division, Air Service, for duty.

Capt. Herbert A. Thorndike will proceed to Washington, D. C., and will report upon arrival to the Director of Air Service.

SUBSTANTIAL and remarkable are the achievements of Goodyear balloon men.

Since nine years ago they have built a total of more than eight hundred balloons of all types, including spherical, kite and dirigible.

In gas capacity, these "ships of the air" include even those enormous bags that contain up to one hundred and seventy thousand cubic feet.

During the world war, more than one half of all the balloons purchased by the government were Goodyears.

Goodyear balloons have traveled more than two hundred thousand miles during the last two years, while carrying thirty-six thousand passengers—without a single fatality.

Due then to these achievements, it is only natural that Goodyear men have become balloon designers of unquestioned competence.

We are prepared to submit plans and specifications for any type of balloon desired—from the smaller sizes to the huge Ocean liners.

PATHFINDING AEROPLANE TOURISTS WILL VISIT AIRCRAFT FACTORIES

THE Pioneer Aeroplane Tours of the Aerial League of America announced in the last number of AERIAL AGE are to be preceded by pathfinding tours, the first of which will take the aerial tourists on a visit of the great eastern aircraft factories.

In the first pathfinding tour the aerial tourists will fly to and inspect the following aircraft factories:

They will start from the Atlantic City Airport and fly to Keyport, New Jersey, and visit the plant of the Aeromarine Plane and Motor Company at Keyport.

From Keyport they will fly to the Roosevelt Field at Garden City, Long Island, where they may stay overnight and visit the plant of the Curtiss Aeroplane and Motor Corporation at Garden City the following morning .

Then they will fly to New Brunswick, New Jersey, where they will visit the Wright Martin Aircraft Corporation, the makers of the famous Hispano-Suiza motors.

Next they may stop at Trenton and visit the Roebling plants, which make, among other things, the wire, cables, and other metal products used in the construction of aeroplanes.

They will then fly to Philadelphia and may visit the Naval Aircraft Factory as well as the Unit Construction Company. Time permitting the tourists will also visit the Hess-Bright Manufacturing Company, The Carlson-Wenstrom Company, and the Janney-Steinmetz Company.

The Committee in charge of arranging the Pathfinding Aeroplane Tours includes: Major Reed, G. Landis, second ranking American Ace, Captain Charles J. Glidden, John P. Davis, Major Redonds B. Sutton, veteran U. S. Army Aviator; Henry Woodhouse, Inglis M. Uppercu, Earl L. Ovington, Joseph A. Steinmetz, president Aero Club of Pennsylvania; Albert T. Bell, president Atlantic City Aero Club; G. Douglas Wardrop, and Major Harry Bubb.

In the pathfinding tours to follow, the tourists will visit the aircraft factories at Ithaca, Rochester, Buffalo, Erie, Cleveland, Toledo, Detroit, Dayton, Indianapolis, Chicago, and other cities.

$65,000,000 TO BE APPROPRIATED FOR ARMY AND NAVY AERONAUTICS

THE House and Senate have approved the conference reports on the army and navy appropriation bills, which save the army air service from disintegration and enable the navy to embark on its plans for development of a lighter-than-air programme as already outlined by Secretary Daniels.

The conferees agreed upon giving army aviation $40,000,000, instead of the $15,000,000 originally appropriated by the House, and $25,000,000 for naval aviation instead of the $15,000,000 decided upon by the House, and the $35,000,000 asked by the Secretary of the Navy.

Definite indication of the navy's intention to embark at once on an extensive experimental and building programme with lighter-than-air craft is indicated in the itemized statement of naval appropriation allowances.

The largest single item is that of $6,700,000 for continuing experiments and development work for all types of aircraft. In line with this appropriation are $3,700,000 for construction of two large dirigible hangars on government land, $1,500,000 for construction of a dirigible, $2,500,000 for purchase abroad of a dirigible of the latest type, $500,00 for conversion of the collier *Jupiter,* sister ship of the missing *Cyclops,* into an aeroplane carrier, $100,000 for purchase abroad of five special type 'planes and $700,000 for conversion of two merchant vessels into aircraft tenders.

In addition, $3,027,250 is allowed for fleet aircraft purposes; $3,008,007 for maintenance and operation of an aircraft factory, helium plant and aircraft stations.

ALLIES' CONVENTION OUTLINES AERIAL NAVIGATION RULES

AN international convention setting forth the medical requirements for aerial navigation as adopted by the Aeronautical Commission of the Peace Conference at Paris was made public in Washington. Although this international convention was adopted at Paris on April 12 and was sent to Washington several weeks ago, it was to be kept confidential until the signing of the Peace Treaty. It fixes 19 years as the minimum age for air pilots and navigators, stipulates physical and medical requirements, and provides that every candidate before obtaining a license as pilot must present himself for examination.

The requirements set forth in the convention are minimal. Each State may change the conditions, as it deems fit, but these minimum requirements should be maintained, in the opinion of those who signed the convention on behalf of the five principal allied powers, the United States, Great Britain, France, Italy and Japan. Here is the text of the international agreement:

"International medical requirements for aerial navigation.

"1. Every candidate before obtaining a license as a pilot, navigator, or engineer of aircraft engaged in public transport will present himself for examination by specially qualified men (flight surgeons) appointed by or acting under the authority of the contracting State.

"2. Medical supervision, both for the selection and the maintenance of efficiency, shall be based on the following requirements of mental and physical fitness:

"(a) Good family and personal history, with particular reference to nervous stability. Absence of any mental, moral or physical defect which will interfere with flying efficiency.

"(b) Minimum age for pilots and navigators engaged in public transport shall be nineteen (19) years.

"(c) General surgical examination: The aeronaut must neither suffer from any wound, injury or operation nor possess any abnormality, congenital or otherwise, which will interfere with the efficient and safe handling of aircraft.

"(d) General medical examination: The aeronaut must not suffer from any disease or disability which renders him liable suddenly to become incompetent in the management of aircraft. He must possess heart, lungs, kidneys, and nervous system capable of withstanding the effects of altitude and also the effects of prolonged flight.

"(e) Eye examination: The aeronaut must possess a degree of visual acuity compatible with the efficient performance of his duties. No pilot or navigator shall have more than two (2) dioptres of latent hypermetropia; muscle balance must be good and commensurate with the refraction. He must have a good field of vision in each eye and must possess normal color perception.

"(f) Ear examination: The middle ear must be healthy. The aeronaut must possess a degree of auditory acuity compatible with the efficient performance of his duties.

"(g) The vestibular mechanism must be intact and neither under hypersensitive nor hyposensitive.

"(h) Nose and throat examination: The aeronaut must possess free nasal air entry on either side and not suffer from serious acute or chronic affections of the upper respiratory tract.

"3. Each contracting State shall for the present fix its own methods of examination until the details of the tests and the minimal standard of requirements have been finally settled by the authorized medical representative of the I. C. A. N.

"4. The successful candidate will receive a medical certificate of acceptance which must be produced before the license can be issued.

"5. In order to insure maintenance of efficiency every aeronaut shall be re-examined periodically, at least every six months, and the findings attached to his original record. In case of illness or accident, also, an aeronaut shall be re-examined and pronounced fit before resuming aerial duties. The date and result of each re-examination shall be recorded on the aeronaut's flying certificate.

"6. No aeronaut who, before the date of the present convention, has given proof of his flying ability, shall, so long as he retains such ability, be necessarily disqualified because he fails to fulfill all of the above requirements.

"7. Each contracting State may raise the conditions set forth above, as it deems fit, but these minimal requirements shall be maintained internationally.

"Signed by the representatives on behalf of

"United States: Isaac H. Jones, James B. Stanford.

"Great Britain: Martin Flack, A. P. Bowdler.

"France: George Cuillain, Jules Levaire.

"Italy: Lieut. Col. Guideni, signing for Di Nola and Mattoli.

"Japan: K. Miura.

"Paris, April 12, 1919."

WHAT NEXT?

WHAT does there remain for aeroplanes to do now that the Atlantic has been crossed? was the question asked of the representatives of different countries assembled at the Atlantic City airport to witness the tests of the British Guardian Angled parachute. Thereupon they practically resolved themselves into a committee for the discussoin of the future of aeronautics, and what was forecast would make Kipling and Jules Verne appear conservative. The party, some of whom are very old-timers in aeronautics, included Capt. Pierre Bosc, member of the French High Mission, who served in the French Air Service since the beginning of the war; Capt. Carlo Tappi, acting Italian Air Attaché, who has been in the Italian Air Service since 1911, when he was one of the Italian aviators who fought the Turks on African soil; Major Orde Lees, who has been in the British Air Force for a number of years; Henry Woodhouse, vice-president of the Aerial League of America, who has been foremost in fostering the development of aeronautics for the past ten years; Earle L. Ovington, the veteran American aviator, who made the first aerial mail experiment in 1911; Albert T. Bell and Harry B. Cook, of the Aero Club of Atlantic City, who organized the meet in 1910 at which Glenn H. Curtiss and some of the other early aviators flew, and where the then marvellous altitude record of 5,000 feet was made. Now the altitude record is 33,000 feet; also A. S. Abell, 3rd, of Baltimore, who participated in the flying events held in that city in 1910; Joseph A. Steinmetz, who has been president of the Aero Club of Pennsylvania for the past six years; Eddie Stinson, the veteran aviator, and others.

After witnessing the convincing tests and demonstrations of the remarkable "Guardian Angel" parachute aerial life preserver at the Atlantic City airport, the experts, as usual, gathered at the beautiful home of the Abell family on the Boulevard, near the airport, which has been named "Pilots' Port and Aeronautic Arcadia," and there discussed the future of aeronautics from every standpoint.

Captain Bosc told of stupendous flights made by French aviators across the African deserts, across the Mediterranean Sea and across the Great Atlas Mountains; Captain Tappi told of flights made by Italian aviators in Africa, and of aeroplane passenger-carrying lines across the Apennine Mountais; Major Orde Lees told of flights of British aviators from London to Africa and to India, and of plans to establish aerial transportation lines throughout the British Empire.

Henry Woodhouse, vice-president of the Aerial League of America, summarized the things that still remain to be done by aeroplanes as follows:

"The magnificent flights of the American and British aviators have just opened the tremendous possibilities for aerial achievements.

"Here are a few of the things still to be done:

"(1) Cross the Atlantic by direct flights from the United States to England, France and Italy.

"(2) Carry one thousand pounds of mail in a non-stop direct flight from the United States to England, thereby demonstrating the utilitarian value of trans-Atlantic air lines.

"(3) Make a non-stop flight from New York to San Francisco first, then carry a thousand pounds of mail or passengers on subsequent flights.

"(4) Fry from New York to San Francisco within one day's daylight.

"(5) Cross the North Pole from Cape Columbia to Cape Chelyuskin, as proposed and planned by Capt. Robert A. Bartlett.

"(6) Fly to Hawaii.

"(7) Fly to the Philippines.

"(8) Fly across the Pacific.

"(9) Complete the aerial conquest of the Atlantic by flying it by each of the following routes:

"(a) By way of the Azores, then to Madeira, then to either Spain or Africa;

"(b) From South America to Barbadoes and across to the Canaries;

"(c) From Cape Orange to Cape Verde and then to the African coast;

"(d) From Pernambuco to St. Paul Island, then either to Cape Verde or straight to the African coast;

"(e) By way of Greenland and Iceland to the Faroe Islands and from there to England.

"(10) Fly to Australia and New Zealand.

"(11) Fly across Alaska and demonstrate how aerial transportation will help that rich country.

"(12) Fly from the United States to Brazil and Argentine, and also from the United States to Chili and Peru and other Latin-American countries, and show the marvellous possibilities of aerial transportation in South and Central America.

"(13) A great many high mountains still remain to be conquered by air.

"(14) The deserts still are to see the permanent air lines which will make travel pleasant even across deserts.

"I could go on quoting at least fifty more things which should be done, but these give a good idea of what remains to be done by aircraft. As I have said, the splendid achievements of Commander Read and his gallant crew, and of Captain Alcock and Lieutenant Brown, have only just opened the possibilities for real achievements in aeronautics and for making aircraft useful to the world."

THE NEWS OF THE WEEK

Iceland Establishing Air Service to U. S.

Washington, D. C.—According to official advice, Iceland intends to establish a regular air service between Reykjavik, its capital, and the Eastern ports of the United States.

P. A. Olafson, consul at Reykjavik, is quoted as saying that two hydro-aeroplanes, with sufficient power to accomplish a trans-Atlantic flight, are already in commission, and that a large aeroplane corporation has been formed to bring about regular aerial voyages between Iceland and the United States. The present two hydro-aeroplanes will be "tried out" in the circumnavigation of Iceland.

The American-bound plane will "take off" at Reykjavik and fly about 500 nautical miles to the southern tip of Greenland, where facilities will be provided to refuel and repair any damages. The next stretch will be approximately the same distance, from Greenland to Newfoundland, and thence to the United States. The same route will be taken on the return trip.

Atlantic City-Long Island Record Again Broken by Sopwith Camel

Atlantic City, N. J.—Another flying record was established on June 28, when Lieut. Kenneth M. Murray, in a Sopwith camel, flew here from Mineola, L. I., in fifty-one minutes. Lieut. Murray left Mineola at four minutes past twelve o'clock and landed at five minutes before one. He clipped ten minutes off his flight of June 24 from here to the Long Island field. The flyer was congratulated on his arrival at the Airport by officials and a large number of spectators.

Lieut. Murray fought through a northeast storm and a fifty-mile gale.

Worcester Landing Field Being Selected

Worcester, Mass.—Realizing the importance of establishing adequate aerial landing facilities along the New York-Boston air route, Mr. J. Walter Flagg and other interested business men have been deciding on the most suitable tract in or near Worcester which can be made into a first-class landing field in accordance with Government specifications. Airmen who have flown over Worcester regard it as an excellent locality for a landing place, there being a marked absence of rough air and pockets.

Two sites are under favorable consideration, one on Brattle Street, a part of the A. S. Lowell estate, the other on Newton Hill.

Lieut. Quick in SVA Scout to Bring Willard-Dempsey Photos for New York Paper

The practical value of the aeroplane will be subjected to a good test in connection with the Willard-Dempsey fight, for the New York *World* has arranged to despatch a fast machine from Toledo, immediately on conclusion of the fight, with photographs of the event designed for publication in the *World* on the following morning.

The machine is an Italian SVA, one of the fastest types yet designed, one which did noteworthy service during the war. The pilot of the SVA will be Lieut. Raymond B. Quick, who saw much service with the 95th Pursuit Squadron (American) in France.

The SVA will leave Toledo immediately after the fight. If its flight is successful, the pictures of the fight will be in the papers the next morning.

The ordinary time of delivering these photographs in New York by train would be about fifteen hours; by aeroplane it should be about five.

Prince of Wales to Be Starter for Toronto-New York Aerial Race

Toronto.—An international aerial race, which will start simultaneously from Toronto and New York, will be held on August 25, with the Prince of Wales as the starter, it was announced here recently. Stops will be made at Buffalo, Syracuse and Albany.

A prize of $5,000 and a trophy have been offered by John M. Bowman of New York. It is expected there will be more than two-score entries.

Handley-Page Bomber Flies From Indianapolis to Washington, 505 Miles, In 285 Minutes

Washington.—A Handley-Page bombing plane, carrying two pilots and five mechanics, on June 24 covered the 505 miles between Indianapolis and Washington in 285 minutes. The pilots were Lieuts. G. M. Palmer and G. L. Bradford. No stops were made. Rain fell almost continuously throughout the flight, but did not retard speed measurably.

Huge Aerial Stunting Exhibition at New York Police Field Day

Frederick A. Wallis, Deputy Police Commissioner, announced that the greatest flying exhibition ever witnessed in this country will be held on the afternoons of the police field days, to be held at Sheepshead Bay Speedway Saturday, July 19, and Saturday, July 26.

Mr. Wallis said that fifty-six aeroplanes participated in the army games last August, but that he expected Colonel Miller will have a far greater number participate in the police aerial exhibition, as there are more than twice that number of aeroplanes available at the aviation fields on Long Island.

Kansas City-Fort Worth Air Line to Open July 4th

Kansas City, Mo.—The first regular aeroplane passenger service out of Kansas City will be to Fort Worth, Tex., with stops at Coffeyville, Kan., and Tulsa, Oklahoma City and Ardmore, Okla.

Charles Ora, local manager of the Commercial Airship Syndicate, of Fort Worth, stated a small dirigible would make the trip in July. It is hoped to have everything in readiness for the pilot trip July 4.

Mr. Ora said his company had ordered a "sport blimp" dirigible from the Goodyear Tire and Rubber Company. The July trip will be for the purpose of completing arrangements at stations for landing facilities.

The "Airco 16", a remodelled de Havilland with a salon for 4 passengers. The lower view shows a lady passenger about to enter

R-34 Rapidly Overhauled After 2,000-Mile Baltic Flight

East Fortune, Scotland.—The overhauling of the great British dirigible R-34, in preparation for a flight across the Atlantic, has been so rapid that she is ready to start as soon as ordered to do so. The weather, however, continues unsettled.

It has been necessary to install one new motor and overhaul four others, and to do considerable work on the huge envelope, since the rough trip of approximately 2,000 miles the R-34 made over the Baltic. This work has been pushed as rapidly as possible, so that there may be no further delay in making the attempt to cross the Atlantic.

Handley-Page Still Waiting for Weather

Harbor Grace, N. F.—The Handley-Page trans-Atlantic expedition has entered on the third week of waiting for weather conditions that will make possible a start on the projected flight from Newfoundland to England. When that time may come is more uncertain than ever.

With the abrupt and unexpected changes that have come during the last few days, the aviators have added actual worry to their vexation over the delay. The time is really not far distant when the machine will become physically unfit for its intended task, and the resources of the plant here are such that restoration might prove impossible. In that event, there would be nothing to do but to dismantle and send the huge craft ingloriously back to England by steamship.

Had work been continued on the big portable hangar brought here, it would now be serving a valuable purpose. The hangar, which had been half erected, is, however, merely a jumble of scattered parts, awaiting shipment to Toronto, and the biplane is exposed to the weather, with no protection except tarpaulin covers for the engines and propellers.

The Martinsyde plane is entirely rebuilt and has been under test. Lieutenant Biddlecombe, Captain Raynham's navigator, has been at St. John's for over a week and assisting in the preparations for the attempt to lower the Vickers-Vimy speed record.

Dallas-Boston Flight Record

Washington, D. C.—The Dallas-Boston flight, which was completed on June 23 by the seven De Havilands which left Dallas on May 15, made the following flying schedule, which does not, of course, include the exhibition flights made in the interest of recruiting at the stopping places:

Valspar delivered to Allentown by aeroplane

From	To	Miles	Min.
Dallas	Oklahoma	208	105
Oklahoma	Camp Funston.	300	170
Camp Funston	Topeka	60	45
Topeka	Kansas City....	67	45
Kansas City	St. Joseph & return	80	70
Kansas City	Belleville	285	200
Belleville	Indianapolis ...	210	145
Indianapolis	Chicago	165	100
Chicago	Milwaukee	80	40
Milwaukee	Minneapolis ...	300	195
Minneapolis	Milwaukee ...	375	290
Milwaukee	Indianapolis ...	260	151
Indianapolis	Dayton	110	65
Dayton	Cleveland	200	122
Cleveland	Buffalo	185	132
Buffalo	Albany	260	150
Albany	Boston	130	66
	Total	3276	2091

The average speed for the entire flight is 93.96 miles per hour. The following officers and men participated in the flight: Commanding, Col. H. B. Claggett; Pilots, Major J. W. Simons, Jr., Major Roy S. Brown, 1st Lieut. Jack E. Duke, Jr., 1st Lieut. Benj. H. Adams, 2nd Lieut. John Pulm, 2nd Lieut. Robt. F. Midkiff. Observers, Capt. W. H. Chandler, Capt. Herfluegel, Sgts. 1st Class Ralph Kratz, Wayne Neville, J. A. Smith, Harry H. Aliman.

Talbot Flies From Dayton to Mineola in Six Hours

J. E. Talbot, Jr., president of the Dayton-Wright Aeroplane Company, of Dayton, Ohio, arrived at Mineola from Dayton on June 17 in a DeHaviland aeroplane.

The time of the flight was five hours and fifty-five minutes. Howard Rinehart, a civilian, was the pilot.

Guardian Angel Parachute Demonstrated at Dayton

Major T. Ord Lees, who during the war was in charge of parachute development for the Royal Air Force, is going to McCook Field at Dayton for the purpose of carrying on parachute demonstrations in order that the Engineering Section will be able to take advantage of the work. It may be that after the tests are finished at Dayton the detachment will return to Washington to give demonstrations at Bolling Field.

With Major Lees is Lieut. R. A. Caldwell, D. F. C., who jumps from aeroplanes to demonstrate the adaptability of the parachute. The interesting feature of the party is the presence of Miss Sylvia Boyden, a young lady of twenty, who also jumps from an aeroplane. According to Major Lees, the jumping of this young lady has a wonderful effect on the public in that when they see a lady land safely they have more confidence in parachutes than when a man descends. Miss Boyden is accompanied by Mrs. A. M. Thomas as chaperone.

The first demonstration of Major Lees' parachutes were given at the Atlantic City Airport.

Forest Patrol Fliers Cover 7,615 Miles in Week

Washington, D. C.—Owing to the exceedingly dry weather prevailing, the balloon school at Arcadia has been maintaining aerial patrol both day and night.

During the week ending June 21, the Mather Field Staff, stationed at Sacramento, Cal., made twenty-one flights over the National forests, discovering four fires, which were reported to the Forestry Service at Placerville, Cal. The total mileage of the patrol was 3,000, and the patrol pilots were 53 hours in the air.

The March Field Staff, Allessandro, Cal., made twenty-four trips, occupying thirty-eight hours, covering 2,500 miles. The Rockwell Field Staff, San Diego, Cal., made eight flights in twenty-six hours and twenty-six minutes, covering a distance of 2,115 miles.

Summary for week ending June 21, not including the balloon observation: Minutes in the air, 7,046; miles of flight, 7,615; number of flights, 53; number of officers and men participating, 15.

The Fiat BR Biplane, with a speed of 160 miles an hour, is powered by a 700 H.P. Fiat engine, the type which will be used for a trans-Atlantic non-stop flight

RETURNING NC FLIERS ACCORDED ENTHUSIASTIC WELCOME

GREETED down the bay by five seaplanes, two blimps, and a score of naval and private water craft, bearing their families, official committees, and hundreds of well-wishers, Lieutenant Commander Albert Cushing Read, U. S. N., and the crew of the victorious NC-4, first air machine to cross the Atlantic, returned to New York on the transport *Zeppelin*. On board the *Zeppelin* were also Commander John H. Towers of the NC-3 and Lieutenant Commander P. N. L. Bellinger of the NC-1 and members of their respective crews. Leaden skies and a steady downpour interfered with the success of the aerial demonstration planned in their honor, but the enthusiasm of those who braved the elements to welcome the aviators was not lessened. Outside the piers at the Port of Debarkation, Hoboken, a crowd waited for the appearance of the aviators and gave them a send-off as they rode away in automobiles.

When word was received that the *Zeppelin* had reached Quarantine, the official boats started down the bay. The submarine chaser *Herreshoff*, carrying the wives and relatives of the returning aviators and the *Manhattan* with a delegation from the Aero Club of America.

The *Manhattan* carried men most prominent in aeronautical circles in this city. She also had on board J. F. Towers, brother of the NC commander, and his wife, and Miss Mary Towers, a sister of the commander.

Others on board were Glenn H. Curtiss, Alan R. Hawley, Rear Admiral Bradley A. Fiske, Captain Robert A. Bartlett, Major S. H. Mapes, Major G. A. Pollock, Henry Woodhouse, Colonel W. G. Barker, the Canadian ace who has sixty-eight Germans to his credit; H. Pushae Williams, president of the Queens Chamber of Commerce; W. W. Mountain, Evan J. David, E. V. Hazelton, H. B. Childs and G. Douglas Wardrop.

The several welcoming committees gave the airmen a noisy greeting. The *Zeppelin* did not stop in the lower bay, as is usually the custom, but continued up the river with its escort of welcomers. The seaplanes did not continue all the way to the piers.

As the *Zeppelin* slipped into Pier 4 at the port of debarkation, a military band broke forth into the tune of "Hail, hail, the gang's all here," while the group on the pier cheered the men who were lined along the railing of the top deck. With Commander Towers leading, the fliers walked off the steamship and lined up in single file, the NC-1 men having the place of honor at the extreme right. Salutes were exchanged between the commanders and Rear Admiral James H. Glennon, representing Secretary Daniels, following which the latter said:

"In the name of the Secretary of the Navy I welcome you home and congratulate you upon your splendid achievement which has reflected so much lustre on

McCullough, Colonel Archie Miller, Rear-Admiral Glennon and others upon their return to the United States

The AIRCRAFT TRADE REVIEW

Wright-Martin Merger Details Revealed

The details of the merger proposal submitted to the stockholders of the Wright-Martin Aircraft Corporation, which provides for virtual absorption of the Wright-Martin Company, with its $7,000,000 in cash, by the International Motor Truck Company, are as follows:

Wright-Martin Corporation preferred stockholders will receive in exchange for their stock first preferred stock of the International Corporation having a par value equal to par value and accumulative dividends of Wright-Martin Corporation preferred stock deposited.

Wright-Martin common stockholders shall receive 2.8 shares of second preferred stock of a par value of $100 each and two shares of common stock without par value of International Corporation for each 100 shares of Wright-Martin common stock.

Wright-Martin common stock shall be reduced so that for each 100 shares of common stock there shall be issued twenty-five shares of Wright-Martin stock in addition to the stock of the International Corporation stock to be taken in exchange.

The date to which accumulated dividends on the deposited Wright-Martin preferred stock will be paid in International first preferred stock will be fixed not earlier than September 1, 1919, nor later than the issuance of the new stock.

If the plan is accepted the Wright-Martin company will sell to the International Corporation all of its properties at New Brunswick, N. J., with the possible exclusion of certain motors and machinery acquired especially to fill government contracts. Other property will be retained by the Wright-Martin company. This will include its agreement with the Hispano-Suiza company granting license rights in the United States; interest in the cross license agreement of aeroplane patents; Wright patents and Simplex patents; interest in the United States Government war contracts for Hispano-Suiza engines and the lease of the Simplex Service Station in Long Island City with equipment and inventory.

Dr. Cantu, Caproni's Business Representative, Arrives Here

Dr. G. Cantu, formerly in the Italian Air Service, arrived recently in this country, coming from England, where he has been for some time making connections with British concerns in behalf of the Caproni Company.

He will act in the United States as business representative for the noted Italian designer, Mr. G. Caproni, and will be assisted in his work by Captain U. V. d'Annunzio, former chief engineer of the Caproni Company.

Dr. Cantu brought with him very interesting data concerning the new five-engine passenger triplanes now in production in the Milan plants of the Caproni Company.

Dr. Cantu has made his headquarters at the Biltmore Hotel, New York City.

Courses in Aeronautical Engineering at the University of California

Berkeley, Cal.—The curriculum in Mechanical Engineering at the University of California will hereafter include a course in Aerodynamics, given in the senior year. An endeavor will be made to present the fundamental principles underlying the design and construction of the aeroplane, and to trace the application of these in commercial types of recognized merit.

A laboratory is being equipped with an aeroplane, type Curtiss JN-4D, with a vertical and a rotary aeronautical engine, and with miniature wind channels for student use.

The treatment of internal combustion engines is being altered to include the design principles of the aeronautical engine.

The course is at present a part of the Mechanical Engineering curriculum and it is the intention to continue it as such for some time to come. The addition of this work broadens the present curriculum for mechanical engineers by including aerial transportation in the general transportation problem.

Champion Spark Plug Salesmen Hold Convention at Toledo

Toledo, Ohio.—The seventh mid-year sales convention of the Champion Spark Plug Company, held in Toledo the week of June 9-15, was a record-breaker in many respects, particularly from an attendance standpoint. Over 125 factory representatives of the big Toledo concern answered present to the roll-call on Monday morning, this being the largest gathering of salesmen ever brought together by a manufacturer of spark plugs.

The convention program this year included regular business sessions every morning and afternoon, at which officials of the company, heads of the different departments and a number of specialists in other lines of business addressed the men on various subjects relating to salesmanship. The opening day was devoted to talks by officials of the company. President R. A. Stranahan welcomed the men to Toledo and Sales Manager Caswell spoke on "Selling Without Misrepresentation." Robert Martland, secretary California Trades Association, addressed the afternoon session, followed by H. L. Corey, advertising manager, and O. C. Rohde, chief engineer of the Toledo concern. In the evening, special cars were run out to the Toledo Yacht Club, where dinner was served.

On Tuesday morning the sales force left for Detroit to inspect the Jeffery-Dewitt plant, where the famous 3450 Champion insulators are produced. A new leer or tunnel kiln over 300 feet long was the chief center of attraction, although every step in the art of making porcelain proved a study in itself. After a luncheon at the Detroit Athletic Club, the delegation of salesmen crossed over to Windsor, where special cars were waiting to take them out to the site recently purchased by the Champion Spark Plug Company for its Canadian plant. Mayor Winter and a number of other Windsor officials were present for the ground-breaking ceremonies, the Mayor turning the first sod. The return trip to Toledo was made by boat, everyone enjoying the five-hour sail down Lake Erie.

The rest of the week was devoted largely to business sessions at the Champion Convention Hall. The big banquet of the week was held at the Toledo Club on Thursday evening, the feature of which was the distribution of cash prizes awarded by Mr. Caswell to members of the sales force. Seventy-three prize checks totaling several thousand dollars were given to those who had shown unusual ability during the past year.

Friday and Saturday the men were grouped for special class meetings supervised by the territorial managers. Saturday night saw most of the salesmen on their way back home.

Salesmen of the Champion Spark Plug Co. assembled at the Sales Convention at Toledo held June 9 to 15

New York-Chicago Aerial Mail Flight Made in Eight Hours

In a trial flight of the New York-Chicago aerial mail route, one of the mail planes on June 25, covered the 745-mile distance between the two cities in eight hours, making stops at Bellefonte Park, Pa. and Cleveland, Ohio.

It is expected that four aeroplanes will be operating regularly between New York and Chicago by July 1. The aeroplanes will leave New York for the first lap of the trip each morning at five o'clock, the final aeroplane delivering the mail in Chicago at one o'clock in the afternoon of the same day.

Although for the present the aeroplanes now in service will be used, the post office authorities intend to put on much larger machines in the autumn, and expect that the excellent time made yesterday will be bettered.

It is intended that the number of aeroplanes will be materially increased as the need for them and the certainty of the service is established. Army aviators are eligible as pilots for the service, and a limited number will be taken on within a short time.

Bids for Aerial Mail in Colombia Asked By P. O. Department

Tenders are being invited by the Government of Colombia for the conveyance of mails by aeroplane, or airship between Bogota and Barranquilla, between Bogota and Pasto, and between Bogota and Cucuta; on each route there will be several landing points. The contractors will have to be responsible for the mail matter conveyed in their machines, except in cases of fortuitous mishaps, duly proved. A fine up to $5,000 is to be paid by the contractors should they fail to transport the mails by air. The first contract will be for four years, and may then be renewed from year to year. Tenders have to be sent to the Colombian Postmaster-General by next September, and it is hoped to start the services in June of next year.

John M. Miller, Formerly Naval Aviator, Piloted Aero Mail Plane Through Winter's Worst Storm

John M. Miller, now in the Aerial Mail Service, received his first aeronautic experience at the Burgess Co. of Marblehead, Mass., and later at the Sturtevant Co. of Boston. He enlisted in the Naval Air Service on May 23, 1917, and was ordered to active duty at the Massachusetts Institute of Technology Ground School. After two months here Miller received elementary flying instruction at Hampton Roads and advanced instruction

Ensign John Matthew Miller, now piloting De Haviland biplanes for the Aerial Mail Service

at Pensacola. He was commissioned on March 16 and ordered to the Rockaway Naval Air Service.

Here Miller did patrol and convoy work off New York harbor, acting as division commander for two months, then being advanced to the position of assistant squadron commander, which he continued until ordered to inactive duty on December 15, 1918.

Since entering the postal service he was stationed at Belmont Park for D. H. instruction; then he was ordered to Bustleton as station manager. While stationed here he made a trip from Philadelphia to New York in the worst winter storm recorded in some years. On May 16 he made his first flight on the Western Division between Cleveland and Chicago, which was the second flight over that route. On May 22 Miller made the first non-stop flight between Cleveland and Chicago.

Aeroplane Mail Cheaper Than Railway Mail

Washington, D. C.—In explaining the reasons for the forwarding of ordinary mail by means of aeroplanes, the Post Office stated that $62,000 has been saved over the Chicago-Cleveland route since its inception several weeks ago. The railway mail rates are based on weight and the Post Office Department has found it more economical to employ aerial mail than railway service.

Philadelphia-Atlantic City Aerial Passenger Service Starts

Atlantic City, N. J.—Inaugurating the Philadelphia-Atlantic City Air Service, James S. Clark, Assistant Secretary of the Land Title and Trust Company of Philadelphia, was the first passenger arriving at Atlantic City on June 25. Clark chose the aerial route for the shore to attend the convention of the National Association of Real Estate Boards.

Frank Mills, head of the flying school field at Essington, piloted the craft. The pair left Essington at 9:20 June 25, manoeuvered over the Land Title Building in Philadelphia and then went to Atlantic City by way of Cape May, flying against a direct head wind. They arrived at the Curtiss flying field here at 11:30 A. M.

Lincoln Aero Club Establishes Landing Field

Lincoln, Neb.—The Lincoln Aero Club has opened a landing field on a very level sixty-acre tract, donated to the Club by Mr. Mark Woods of Lincoln. Fences have been erected and parking space for 250 motor cars provided.

The citizens of Nebraska have taken an enthusiastic interest in flying. The passenger booking office on the field has attracted more business than can be taken care of. Six Curtiss planes have been delivered by the local agency and three more are on order. In this section, as throughout the country, aeroplanes are playing an important part in Fourth of July celebration plans.

Former Army Flier Goes to Commencement By Air

Middlebury, Vt.—Charles S. Jones, of Rutland, left Roosevelt Field, Mineola, L. I., in an aeroplane at ten o'clock on June 19 and landed at the Addison county fair ground here at quarter to five o'clock the next day. Jones, who won the Croix de Guerre while serving as an aviator in France, took this method of coming to attend the Middlebury College commencement. He was the leading athlete of the class of 1915 at Middlebury.

Ralph H. Mann, of Worcester, Mass., on his way to the University of Vermont commencement, accompanied Jones.

LAWSON AERIAL TRANSPORT

THE giant Lawson "C-1" biplane was designed from a strictly commercial point of view and is the first of a number of this type now being built for a trans-continental service between New York and San Francisco to be known as the Lawson Air Line.

The fuselage is built to accommodate 26 passengers and all the details of its construction and performance characteristics take into consideration the safety and comfort of the passengers. In this regard the machine possesses a high degree of inherent stability, a very flat gliding angle which is imperative in a machine of this kind, and a factor of safety which is relatively high. The machine is readily manœuvred in the air and on the ground, for the control surfaces are of such generous proportions and so well balanced that at all times control is positive. Controls may be set and locked when the course is smooth, relieving the pilot from the strain of constantly working the controls.

The seats are readily detachable and sleeping quarters installed for a fewer number of passengers when cruising for considerable distances.

The general specifications of the Lawson Air Transport "C-1" are as follows:

General Dimensions

Span, both planes	85′ 0″
Chord, both planes	9′ 6″
Gap	9′ 3″
Length overall	47′ 7″
Height overall	14′ 0″

Areas	*(sq. ft.)*
Main planes, including ailerons	1,700
Ailerons (4)	168
Stabilizers (2)	172.5
Elevators (2)	57.5
Rudders (3)	52

Angles

Incidence of main planes	3°
Dihedral	1°
Sweepback	6°
Stabilizer setting to wing chord	0°

Weights

Machine fully loaded	12,000 lbs.

Performances

Climb in 10 minutes with full load	4,000 ft.
Ceiling	15,000 ft.
Gliding angle	1 to 8
Fuel duration	5 hours
Flight duration	500 miles

Main Planes

U. S. A. 5 wing section is used. Main planes are in seven sections. The outer center section extends between the outer struts of either engine nacelle. The two lower center sections run from the fuselage to outer engine nacelle struts.

Wings have a factor of safety of 14, which is rather high when it is considered that usually the safety factor is 8. The wings are strongly braced internally and externally by cables which are double in every case. Wing struts are of wood.

Fuselage

Seats are placed at windows at each side of the body, and an aisle between the seats allows passage from the front and rear of the cabin. On the left side of the cabin forward of the wings an entrance door is provided. This door is of such proportions that the usual method of climbing or crawling into the machine is done away with.

To enter or leave the machine one of the pilots' seats is swung out of the way. All seats are of wicker construction upholstered with green leather. They are secured to the floor and provided with safety belts. The interior is finished in mahogany. The floors are covered with carpet. The depth of the body allows one to stand up without stooping when walking through.

The forward part of the body is covered with veneer and the rear of the cabin section is covered with fabric. Internally, both veneer panel struts and wiring is used for bracing. All cables are hidden from view. Longerons are of solid section ash on their forward ends, and spruce in the rear.

Controls

Dual controls are provided at the forward end of the cabin. Control wheels are 18″ in diameter and are mounted on a tube extending from one side of the body to the other. The wheels control the ailerons and elevators, and the usual foot bar is used for the rudders. All control surfaces are interconnected and cables doubled.

In the ailerons wood is used in the construction. For the stabilizers and elevators both wood and steel are used. The rudders are nearly all steel. For night flying, electric lights are supplied for the instrument board, interior of the cabin, and the wings.

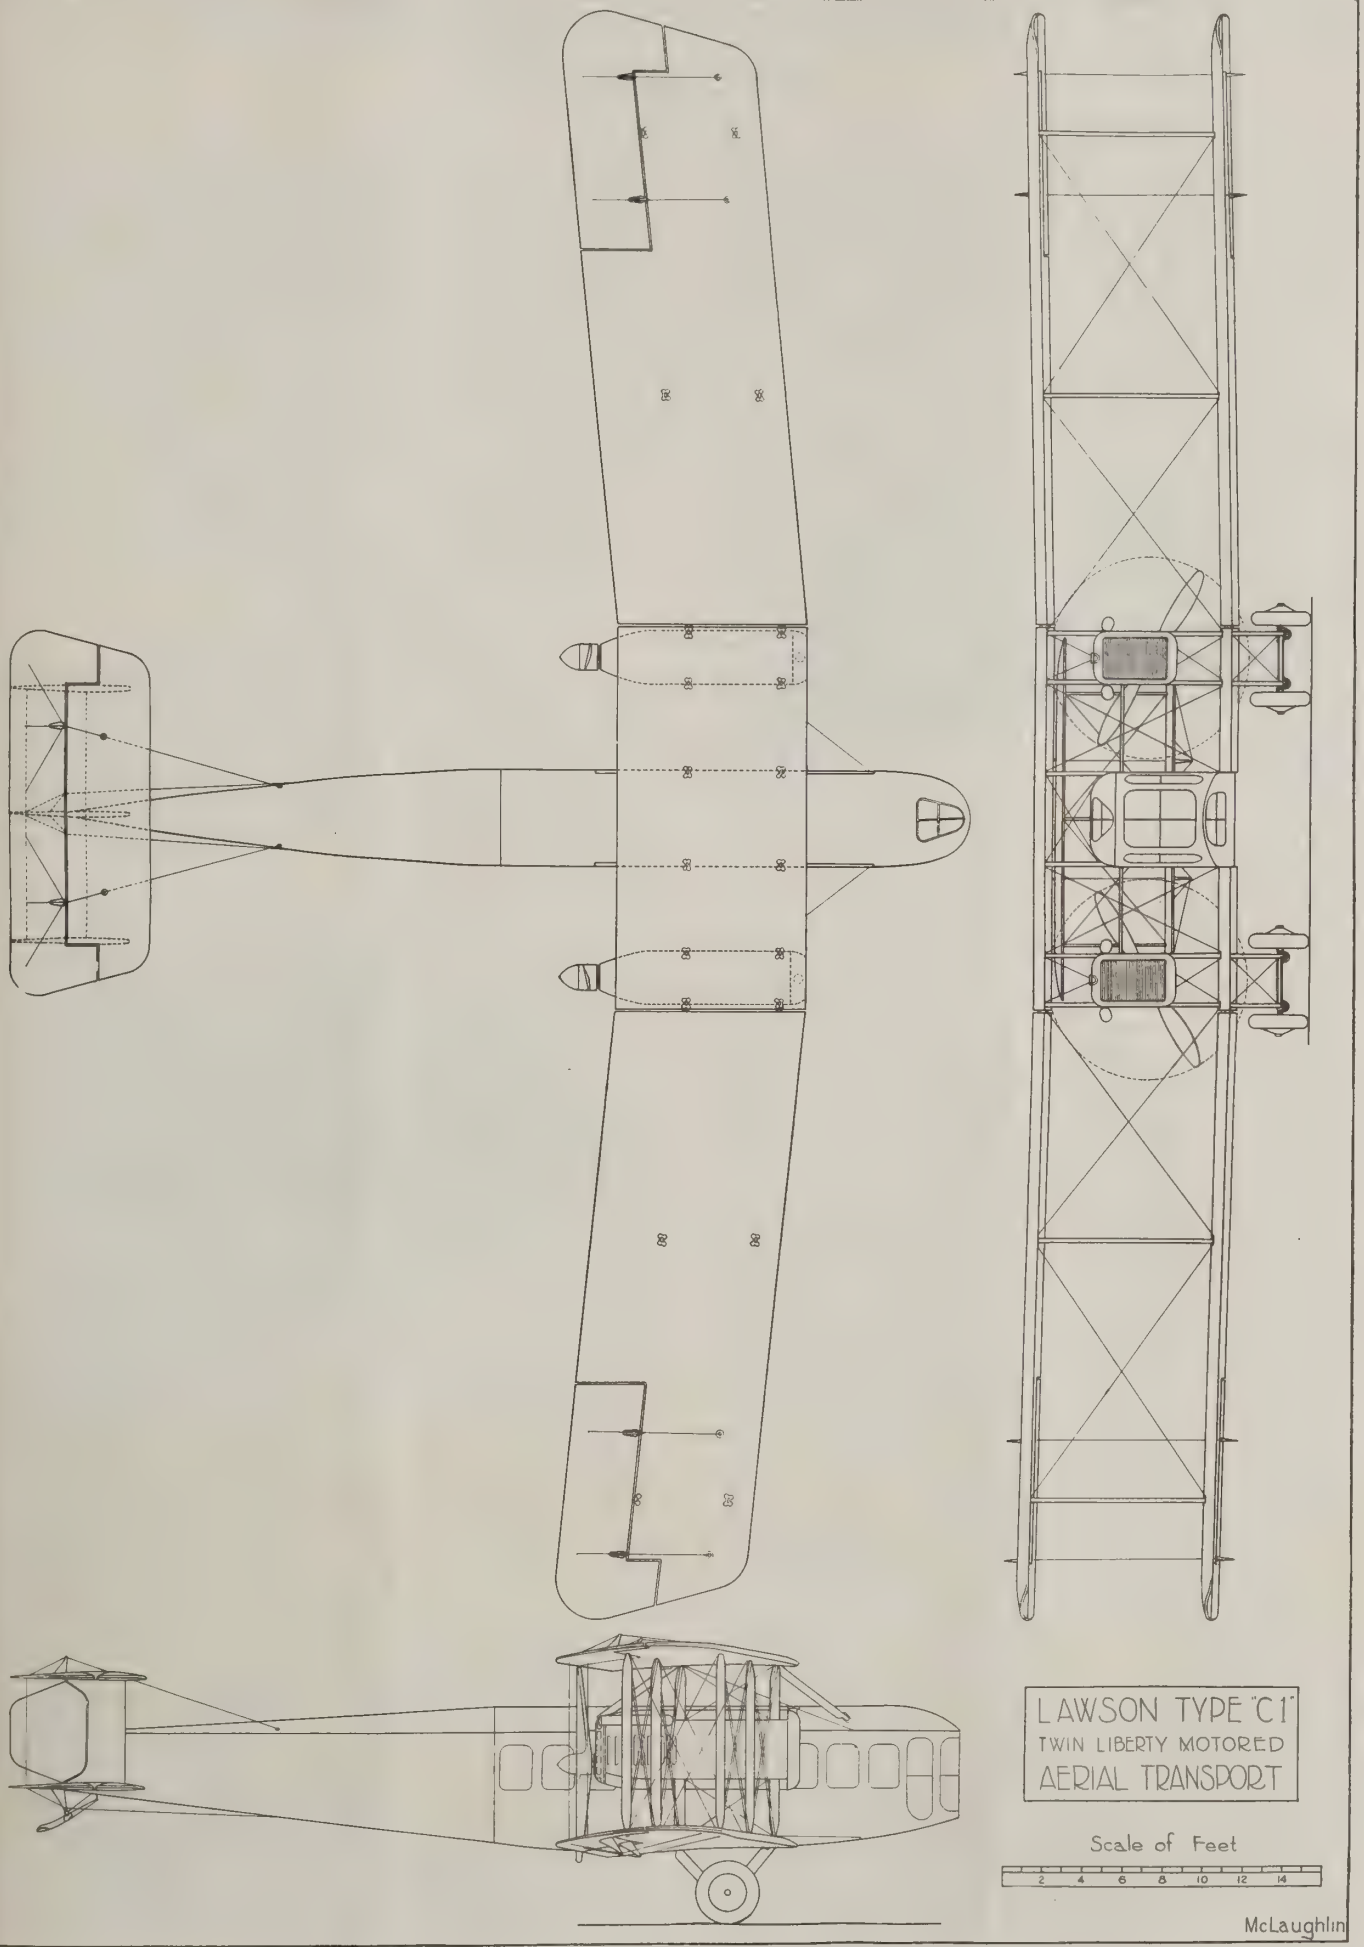
Tail Group

The fuselage terminates in a steel tube stern post to which is attached a rear spar of the lower tail plane and also tail skid. The tail, of the biplane type, is adjustable to counteract any differences in balancing which may ensue. Due to the large size of the machine, passengers may move freely about the fuselage without any disturbance to plane. Rudders and elevators are of the balanced type.

Landing Gear

The landing gear is composed of two pairs of 36″ by 8″ wheels carried on large streamlined steel tube struts. They are attached under each engine in such a way as to evenly take up the landing shocks with a minimum of strain to the wings and fuselage.

Engines



Two 12-cylinder Liberty engines are used. They are completely enclosed in nacelles at either side of the fuselage.

Front ends of nacelles are formed by the radiators. Engines are placed in pusher position with propellers 10′ in diameter revolving in opposite directions. They rest on large ash beds internally braced by steel tubes. Gas tanks are located in the nacelles. Engines are equipped with separate controls to the pilot's compartment, where they may be operated separately or together.

Effective mufflers are provided which add greatly to the comfort of the passengers.

The fuselage of the Lawson Aerial Transport is 45 ft. long, 7 ft. high and 4 ft. 9 in. wide. Provisions are made for seating 26 passengers. Two 400 H.P. Liberty motors are used

THE SPERRY PARACHUTE

By H. E. GOODMAN

A GREAT deal of interest has been aroused by my recent demonstration at the Atlantic City Airport of the Sperry parachute, and readers may find it interesting to know the details of the chute and of its operation.

The diameter of the chute is 23 feet. The descent is made at the rate of about eight miles an hour, which is the equivalent of jumping from a height of about twelve feet. The reason for the small size of the parachute is, strange as it may seem, safety. The larger the chute the greater the strain at the point of opening for a given speed, and when you cut

Harness of the Sperry Salvo Parachute

loose from a high-speed ship a large diameter makes necessary a heavier harness and connections to the parachute as well as stronger fabric throughout. When it is realized that when a jump is made the strain is around 1,200 pounds on my harness it will be appreciated that to increase this strain materially would cause discomfort and the opening would be delayed.

In coming down, I climb out of my harness, standing with one foot in the bottom loop and hanging on to the rope with one hand so that just before touching the ground I can swing free and therefore alight more easily than would be the case if the harness and chute were attached. Should there be a strong wind the parachute would be liable to drag me. Another advantage in this is that the parachute deflates the moment there is no weight attached to it.

An advantage in Sperry's design is that the aeronaut is able to get out of the machine when it is in an abnormal position, such as in a tail spin, on its back, or on one side. This cannot be done with a chute of the type installed under the fuselage, for should the machine be on its back when the jump is made the chute would be dragged over the fuselage, which would be dangerous. With that type also the jumper can get out of only one side of the aeroplane, so that should a wing come off, and he wished to jump from the opposite side of the plane, he could not do so.

A good feature of the cushion type of parachute is that it takes up no extra space in the cockpit, as it simply replaces the regular cushion of the seat. Space in the cockpit is a much needed thing, and besides when you are sitting on the chute you know it is not going to dangle out and get into trouble. I believe the cushion type is most satisfactory, because when I get out of the plane it is my whole weight that is jerking the parachute out of the container, whereas in the pack type it is only the strength of the break cord at the peak that jerks the wad of silk out.

The Sperry chute is arranged with a pig tail of twenty feet which can be attached to the aeroplane. It opens in from one to one and one-half seconds, but should you desire a delayed opening you can get this, not by attaching the rope, but by simply holding the container in your hand until you wish it to release, whereupon the air resistance will jerk the pack open. I used this delayed opening system in getting out of Stinson's plane when it was on its back, because I was afraid that Stinson might come out of his upside-down glide and strike me, because he, of course, always winds up the upside-down glide going in the opposite direction from the direction he goes when I leave the plane. Therefore, I preferred the delayed opening on that occasion, even though it seemed to worry some of the spectators on the ground.

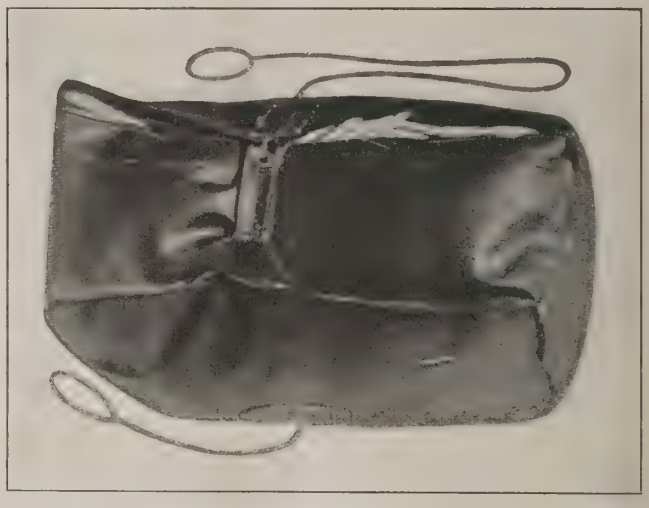
With the type of chute that goes under the fuselage there is danger, especially in high-speed aeroplanes, of the air carrying the parachute into the tail skid, which does not occur in the cushion type, as the jumper is some distance from the aeroplane before the extension occurs.

In the demonstration made of the Sperry Salvo Chute or life-preserver, several distinctive features were brought out:

1. That only five seconds' time is required to make the installation in any plane.

2. The jump can be made from either side of the plane.

3. The jump can be made while machine is flying upside down.



4. There is no difficulty in leaving the plane while in a tail spin.

5. The parachute, not being affected by the high rate of speed in such a way as to become entangled in any part of the aeroplane, it is possible to make the jump during a nose dive.

6. The weight of the entire life preserver equipment is in the neighborhood of 12 pounds.

7. The chute is very compact. It takes the place of the ordinary cushion in the aeroplane and is but slightly larger than such a cushion, thereby not requiring room that is not already available.

8. The harness is remarkable in its lightness (1½ pounds, total weight). It does not interfere with the aviator flying his machine and there is no likelihood of slipping out of the harness at the time that the chute opens. Due to its design, it can be worn by women with special costumes as well as

The compact arrangement of the Sperry parachute, which is used as a seat cushion

men. Its application of strain to the user is in such a way that the minimum tax results.

The device has a safety factor of 40. The harness is tested up to 4,000 pounds.

At the Atlantic City Airport special demonstrations of the Sperry parachute were made before the Contest Committee on parachutes of the Aero Club of America. It was brought out that the above-mentioned points were achieved without resort to complicated mechanism. The simple method employed to extend the parachute and the method of getting away from the slip stream of the aeroplane can be regarded as getting away from any proximity to the plane at the instant the parachute starts to extend.

In regard to the development of parachutes, I might take advantage of this opportunity to mention that Naval Constructor Hunsacker, who is in charge of the Aviation Section of the Bureau of Construction and Repair, has a parachute division in his Bureau. We consider that this division has advanced the art of parachutes for both lighter and heavier-than-air aircraft beyond any other development in this line either here or abroad.

THE GENERAL PROPERTIES AND USES OF PLYWOOD

By B. C. BOULTON, B.S., A.E.

PART II

(*Continued from page 727*)

Plywood Strength Tables

THE very large amount of data available on the strength and other properties of all the common varieties of wood when made up into plywood panels of varying thickness, number of plies, ratio of core thickness to total thickness, and combinations of species, has been collected and summarized in several tables which are reproduced herewith. The woods used in the tests from which these tables were calculated came from various parts of the country, so that slight variations due to locality are eliminated.

Column Tests: Tests to determine the column bending modulus were made on specimens 5 x 12 in. in size. In order that the panel could be computed as a round-ended column, its ends were rounded into a semicircle. The modulus is calculated by the formula $S = P/A + 6M/bd^2$, in which

S = Column bending modulus.
A = Gross area of cross section.
P = Load at maximum moment.
M = Maximum bending moment.
= Px maximum deflection.
b = Width of test piece.
d = Thickness of test piece.

Like the modulus of rupture in the ordinary bending test, the column bending modulus is not a true stress existing in the fibres at the instant of failure, because the elastic limit has been exceeded, but is rather a measure of the comparative strength of plywood in resisting external bending moments. This property includes two factors, a compressive stress and a bending stress, but the former is relatively so small that the column bending modulus can be used and treated as the modulus of rupture.

Fig. 7—Apparatus for Determining Resistance of Plywood to Splitting

In connection with the unit column loading, or P/A factor in a column test, a series of experiments were made on plywood of various thicknesses to determine whether for a given slenderness ratio the length of a plywood column had any effect on its column strength. It was found that the length had no appreciable effect for a large range of values of the ratio of the length of the column to its least radius of gyration. Fig. 3 shows a plywood column ready for this test.

Relative Splitting Resistance: In column 13 of table 1 is given the relative splitting resistance of various types of plywood, as measured by the amount of work required to split a 5 in. square test panel in the apparatus illustrated in Fig. 7. This testing device consists essentially of a sharp pointed plummet or weight that can be dropped from a given height until the test panel is split. The point of the plummet is first embedded slightly in the center of the panel; the weight is then raised to a certain height and dropped. This procedure is repeated until final failure occurs. The amount of work done is the product of the weight of the plummet and the total distance through which it has fallen.

As has been previously noted, resistance to splitting is of importance, principally in connection with the fastening of plywood along its edges by means of screws, nails or bolts. Incidentally, it is important to add that tests have demonstrated the great superiority of screws over any form of nails, a screw being more effective than a nail twice its length.

It will be noticed in table 1 that the splitting resistance of the various species is expressed as a percentage of that of yellow birch. In all the plywood tests this wood has been taken as a standard, and in table 3 certain properties of other species are also expressed as percentages of the corresponding properties of yellow birch.

Table 4 gives the results of tests made to determine the effect of using panels of more than three-plies. The various factors entering into this type of construction have already been discussed. In table 2 are listed the tensile strengths of single-ply and three-ply veneer of various species. Table 3 gives the thickness of a sheet of veneer of any species of wood that will have the same weight as a unit thickness of yellow birch veneer, information of considerable interest to designers. It should be noted that in this table only the relative densities of the woods themselves were considered in computing the thickness factor, and not the densities of glued-up panels. Hence, no account is taken of variations in the amount of glue that different species of wood will absorb. This, as a rule, is greater for open-grained woods than for heavy, dense woods, such as maple and birch. The thickness of any panel that shall have the same strength in bending as a yellow birch panel can be calculated from the thickness factors found in column 6 of table 3. These factors were obtained as follows:

$$M_1 = \frac{S_1 b d_1^2}{6} = M_2 = \frac{S_2 b d_2^2}{6} \quad \therefore d_2 = d_1 \sqrt{\frac{S_1}{S_2}}$$

If d_1 is taken as unity, S_1, the strength of yellow birch in bending, as 100, and S_2 as a percentage of S_1, the thickness factor, $K_s = \sqrt{\frac{100}{S_2}}$, and $d_2 = d_1 K_s$. It should be emphasized that the ratio of core to total thickness must be same for both the birch panel and the one for which the calculation is being made. Also, differences in the number of plies and in the total thickness of the proposed panel may affect this relation somewhat.

In table 5 are given the weights in ounces per square foot of different thicknesses of various species of wood used in aeroplane construction. Using the value for the weight per square foot for a single layer of glue, the total weight of a plywood panel of any thickness, number of plies, or combination of woods can be readily calculated. The results will be as accurate as normal variations in the density of any one species will permit. Here again, however, a slight error is introduced by neglecting variations in the amount of glue absorbed by different woods.

All the tables reproduced in this article were prepared by the Forest Products Laboratory for the Bureau of Aircraft Production. The photographs also were taken in connection with their testing.

TABLE 1

TENTATIVE TABLE OF STRENGTHS OF VARIOUS SPECIES OF 3-PLY PANELS

All plywood was 3 ply with the grain of successive plies at right angles.
All plies in any one panel were of the same thickness and of the same species. Eight thicknesses of plywood ranging from 3/30" to 3/6" were tested.

Design of Various Aeroplane Parts of Plywood

Wing Ribs: Tests have demonstrated that for chord lengths up to 75 in., which, with an R. A. F. 15 section, would give a maximum depth of about 4½ in., the type of construction which employs spruce cap strips, and a plywood web, suitably lightened by holes, is fully as efficient and strong as any built-up or trussed rib, and in addition is more reliable and easier to construct than these types. That there is a limit, however, beyond which the trussed construction is superior to the plywood, is obvious, but only more extended experimentation can determine what this limit is. In the webs of plywood ribs two types of cutouts are used, the circular and the elongate; the latter may be oval or often nearly rectangular, with a length two or three times its depth. Since the vertical members of the web serve to carry compression and horizontal shear, and to prevent buckling of the web as a whole, it is usually best to have the grain of the face plies vertical. This is an illustration of the principle that the grain of the outside plies should be in the direction of a column load. Furthermore, as a function of the web is to act with the flange or capstrip in carrying both compression and bending, it is best to have the core, in which the grain runs parallel to the capstrip, form a large proportion of the total web. Where low density woods are used in both the faces and core, the ratio of core to total thickness should be about 1 to 2; and where high density faces are used with a low density core this ratio may increase to 2 to 3. Among the light woods, Spanish cedar has proved most satisfactory for rib construction; while in the heavier species, combinations of yellow birch or maple faces with basswood or poplar cores are most suitable. Within the range of chord lengths which have been tested the following thicknesses have been found to give good results: For Spanish cedar throughout, 1/40 in. faces and 1/16 in. core; for birch outside plies and poplar core, 1/55 in. faces and 1/13 in. core.

Fuselage Skin: Plywood in fuselage construction may be used merely as covering, or as reinforcement for a truss that is designed to carry either the entire load or a large portion of it. Or, if the fuselage is of the all-veneer type, the plywood shell itself, strengthened by the longerons, carries all the load.

When plywood is used in conjunction with a fuselage truss it is important that it should not wrinkle or buckle. This tendency is more pronounced when the plywood has to lie flat than when it is curved. To decrease wrinkling or similar distortion, the core of the plywood is made relatively thick, and of a low density wood like poplar or basswood, while the face plies are of thin mahogany or birch. In the first application of plywood to fuselage trusses it served merely as a covering to replace linen. Any strengthening it afforded was incidental and was neglected in computing the longerons and wires of the truss. This was of course uneconomical. In later designs the plywood was made slightly heavier and stiffer, and could therefore be depended upon to carry shear stresses, to afford lateral support to compression members, and to bind together and stiffen the entire truss. It was found

*Specific gravity based on oven-dry weight and volume at test.

that all diagonal bracing wires could be omitted and the size of the longerons considerably decreased. The use of diagonal struts, running from the lower longeron at the points of attachment of the chassis struts and flying wires, to distribute the stresses from these members to several points on the upper longeron, is advisable. The ease with which a fuselage of this character can be built, together with its comparative lightness, makes it a close competitor of the newer, all-veneer body.

One of the chief advantages of the latter type is its high aerodynamic efficiency due to the excellent streamlining that can be obtained, and to the fact that changes in the attitude of a plane do not sensibly increase the resistance of such a faired body. In the veneer fuselage, the skin resists all the vertical and horizontal shear, and together with the longerons, it carries the bending moment produced by air loads on the tail surfaces or by dynamic loads. This second function determines that the grain of the face plies shall be longitudinal with respect to the axis of the body, and that of the core, transverse.

Spruce plywood because of its lightness and stiffness has given excellent results, particularly in designs of fairly good depth and moderate length. But for the fuselages of larger, heavier planes, especially those which are relatively shallow or unusually long, a stronger wood such as elm or birch is better. In many instances a combination of elm faces and basswood core is most suitable.

Since the bending moment increases rapidly forward of the rear cockpit, it has been found economical to use more plies in the part of the fuselage extending from just aft of the rear cockpit forward to about the center of the engine section, than in the rear portion of the body. In a comparatively heavy fuselage, for example, this rear section is usually of three-ply veneer and the critical section forward of the rear cockpit, of five-ply. The purpose of the heavy construction near the engine section is to resist the great shearing stresses produced by the engine and fuel tanks. Where the outer plies become unnecessary they taper down to a feather edge. For smaller bodies the skin is three-ply at the critical section, and toward the rear two-ply. In this case fabric often is used between the plies because of the greater toughness and stiffness that it imparts to the skin.

With this general type of fuselage the skin is divided into four longitudinal sections, the top, bottom, and sides. These sections may in turn be spliced transversely at one or more points. The chief function of the top and bottom portions of the skin is to resist bending moment, that of the side sections, to resist shearing stresses. The longitudinal sections join at the longerons to which the plywood is glued, and screwed or nailed. A scarf joint is considered superior to a butt joint, largely because it stands weathering better. In making transverse splices in the plywood it is the best practice to employ a long, glued scarf joint having a slope of approximately 1 to 25, which with 3/32 in. plywood, for example, forms a lap of about 2½ in. Such a joint would usually be made at a bulkhead. Figure 8 shows both longitudinal and transverse splices.

(To be continued.)

HISPANO-
SUIZA
Aeronautical
Engines

Battery of Hispano-Suiza Aeronautical Engines in final test under Government Inspection.

"The Motor that made the Spad possible"

IT is significant that these Government tests are even less exacting than the tests given Hispano-Suiza Aeronautical Engines by this Organization.

It is this policy—a standard higher than is governmentally necessary—which accounts for the remarkable record of this great engine.

New Brunswick, N. J.

NAVAL and MILITARY AERONAUTICS

Army Aviators in Cross Country Flight

Flying from Globe, Arizona, to Phoenix, Arizona, in a De Haviland 4 Lieutenant Wilbur Wright, pilot, with Captain J. T. Darrow, passenger, at an elevation of 7,000 feet passed over the Roosevelt dam and covered the distance between the two points 110 miles in 52 minutes. Topography of the country is exceedingly rough and mountainous.

Lieutenant Henry E. Wooldredge in a De Haviland 4 flew from Ellington Field, Houston, Texas, to Kelly Field, San Antonio, Texas, at a maximum elevation of 8,000 feet, a distance of 210 miles in 95 minutes. Returning in order to pass away from heavy thunder storms he rose to an elevation of 12,000 feet, made a considerable detour to escape the storms and vivid lightning, making the distance of 210 miles exclusive of the detours in 150 minutes.

Lieutenant A. T. Steele carried an Air Service recruit from Birmingham, Ala., back to his station at Montgomery in a De Haviland. The distance of 206 miles was covered in 93 minutes on a speed of 132 miles an hour.

Lieutenant R. S. Worthington on June 17 made what is believed to be a record for an SE-5 single-seater scout by covering the 500 mile distance between Palo Alto and San Diego in 260 minutes, an average speed of 115 miles per hour.

Naval Aviation Officers Get the Legion of Honor

Washington, D. C.—The French Government has decorated more than a score of American naval officers, among them the retiring Commander in Chief of the Atlantic Fleet and some of the higher ranking officers who served in important capacities under Admirals Sims, Wilson and Rodman in European waters, with the order of the Legion of Honor. Among the other officers to be so honored were Lieut. G. J. Romulus, who was at the naval air station at Brest; Lieut. R. E. Read, U. S. N. R. F., who was at naval aviation headquarters in Paris; Ensign E. G. Rose, U. S. N. R. F., and Ensign H. G. Campbell, U. S. N. R. F., who was at the naval aviation station at Brest.

19,000 Hours Flown by Air Service Cadets in Six Weeks

Washington, D. C.—According to a report from the Air Service, from April 3 to June 12, there were over 19,000 hours flown in training of air service cadets. There were eight fatalities in this period, or one for each 2,380 hours of flying.

War Department Turns Over Hispano-Suiza Motors to Navy

Washington.—The Air Service has transferred to the Navy Department 50 300 H.P. Hispano-Suiza engines and spare parts for replacement, according to an announcement of the War Department. The Navy Department acquired the engines and parts at their actual cost to the War Department, which was $227,000. These engines were purchased by the War Department to equip bombing planes.

Colonel Chandler Made Officer of the Legion of Honor

Washington, D. C.—General Collardet, Military Attache, French Embassy, announces that the Government of the French Republic has conferred upon Col. C. de F. Chandler, Chief Balloon and Airship Division, Air Service, the rank of Officer of the Legion of Honor in recognition of the meritorious services rendered by Col. Chandler as chief of the American balloon service in France.

Air Service Fields May Be Used by Civilian Fliers

Washington, D. C.—The following statement has been issued by the Director of the Air Service regarding the employment of Air Service planes and landing fields:

I. 1. Flights in aircraft under the control of the Air Service are authorized for all training or war purposes and such other purposes as are here set forth:

(a) For the proper execution of any approved project of the Air Service or of the Air Service in co-operation with any other branch of the service or department of the Government—special approval of this office to be secured in each case.

(b) For the demonstration of aircraft and aircraft development to officers of the Executive, Legislative and Judicial branches of the Government.

(c) For the rapid transportation of military or civilian officials of the Government, of messages or parcels in cases of urgent necessity and for the convenience of the Government.

(d) For the assistance of stranded civilian aviators or where it is necessary for the saving of human life.

2. The following may be carried as passengers in aircraft under the control of the Air Service:

(a) Any person necessary to be carried as a passenger to accomplish the purpose of any of the flights authorized in Paragraph No. 1, above.

(b) Officers and enlisted men of the Army, Navy and Marine Corps, both active and reserve.

(c) Officers and enlisted men of foreign armies, as a courtesy when they are visiting the United States.

3. No person will be permitted to pilot aircraft under the control of the Air Service except regularly authorized Air Service pilots or bona fide student-pilots of the Air Service.

II. 1. Persons operating aircraft who are not in the military service or who are not under the jurisdiction of the Air Service, will be permitted to use government facilities at Air Service stations contingent upon their proper observance of the air and ground rules in force at the particular station in question, and subject to the discretion of the Commanding Officer thereof as not interfering with the proper conduct of official business of his station, as follows:

(a) They may be permitted to land and

© International Film Service

The Martin Bomber, which will attempt a trans-continental flight with but one stop, undergoing tests at the Army aviation field at Dayton

take-off from Flying Fields.

(b) They may be permitted to place aeroplanes in government hangars over night or for a short time pending repairs.

2. The sale of gasoline, oil, spare parts, etc., or the furnishing of the labor of Air Service mechanics in any form to pilots not in the military service is forbidden.

Demobilization of Air Service

Washington, D. C.—According to reports received from the Air Service the net decrease in the total commissioned and enlisted strength from the date of the armistice to June 12 was 82 per cent.

The following table shows the present distribution of personnel as compared with the figures of November 11, and per cent. decrease. The June 12 figures do not include 417 officers and 2,320 enlisted men in transit to or at demobilization camps awaiting discharge.

	Nov. 11	June 12	Per cent. net decrease
Cadets	6,483	101	98
Enlisted men	170,436	30,237	82
Officers	20,852	4,720	77
Total	197,771	35,058	82

During the week ended June 12, 1919, the decrease in the Air Service personnel overseas was 1,845 as against a weekly average of 1,343 for the four preceding weeks.

The strength of the Air Service in the U. S. and overseas on November 11, January 30, and June 12 is shown in the following diagram:

	U. S.	Overseas
Nov. 11.....	119,882	77,889
Jan. 30.....	46,919	57,527
June 12.....	13,558	21,500

1,351 Discharged Flying Officers Enter Reserve

Washington, D. C.—From the date of the armistice to June 7, 1919, the number of Air Service officers discharged was 14,292; of these 2,530, or 18 per cent. accepted commissions in the Reserve. Following is a comparison of flying and non-flying officers discharged and re-commissioned in the Reserve:

	Number discharged	Accepted Reserve commis'ns	Per cent. accepted Reserve commissions
Non-flying officers	5,654	1,179	21
Flying officers	8,638	1,351	16

Air Service At Sixty Per Cent. of Authorized Strength in Avance Zone

Washington, D. C.—For the week ended May 21, 1919, the Air Service strength in planes operating in the Zone of Advance was 60 per cent. of the authorized strength. Of the planes on hand 65 per cent. were available for service.

In the following diagram is shown a comparison of planes "on hand" and "available" in the Zone of Advance:

	Pursuit	Observation	Total
Authorized strength	25	96	121
Planes on hand....	27	45	72
Planes available....	16	31	47

Special Orders Nos. 139 to 143 Inc.

Second Lieut. Aubrey W. Schofield is transferred to the military hospital, Cooperstown, N. Y., for further observation and treatment.

Second Lieut. Charles H. Dowman is transferred to General Hospital No. 28, Fort Sheridan, Ill., for further observation and treatment.

Capt. John D. Jones will proceed to Washington, D. C., on temporary duty, not to exceed five days, for the purpose of a conference; thence to Hazelhurst Field, Mineola, Long Island, N. Y.

Lieut. Brack-Papa (on left) and Capt. Guido, who will attempt the trans-Atlantic flight in a speedy Fiat biplane

Capt. Harold M. Gallop is relieved from further duty at Hazelhurst Field, Mineola, Long Island, N. Y., and will proceed from Washington, D. C., to Langley Field, Hampton, Va.

Second Lieut. Glen Eyre Wood will proceed to Langley Field, Hampton, Va.

Second Lieut. Herbert E. Metcalf will proceed to Washington, D. C., and report in person to the Director of Air Service for duty.

Capt. Paul P. Robinson will proceed to Carruthers Field, Benbrook, Texas.

Second Lieut. Bernard B. Robinson will proceed to Langley Field, Hampton, Va.

First Lieut. Robert J. Kennedy is relieved from further duty in the Office of the Director of Finance, Washington, D. C., and will proceed to Philadelphia, Pa., and report in person to the zone finance officer for assignment to duty as assistant to the zone property auditor.

Second Lieut. Freeman Albery will proceed to Dayton, Ohio, and report in person to the Chief Engineering Division, Air Service, for duty.

Second Lieut. Thaddeus W. Shackleford will proceed from Camp Little Rock, Ark., to Selfridge Field, Mount Clemens, Mich.

Upon receipt of proper clearances, Cap. Arthur Gosling, Air Service is relieved from his present duties at the Air Service Mechanics School, St. Paul, Minn., and will proceed to Fort Snelling, Minn., for discharge.

The following-named officers are relieved from their present duties and will proceed to the stations indicated: Capt. Guy W. Arnold to Aviation General Supply Depot, Middletown, Pa.; Second Lieut. Michael J. Hurley to Aviation Repair Depot, Speedway, Indianapolis, Ind. and Second Lieut. William J. Tuttle to Taliaferro Field, Hicks, Texas.

Second Lieut. Merle R. Husted is relieved from observation and treatment at the General Hospital No. 2, Fort McHenry, Md., and will proceed to Garden City, Long Island, N. Y., and report in person to the commanding officer, Air Service Depot, that place, pursuant to provisions of Circular Letter 57, S. G. O., 1919.

Second Lieut. Stacey C. Hinkle will proceed to Mineola, Long Island, N. Y., and report in person to the commanding officer, Hazelhurst Field for assignment to duty with the 3d Aero Squadron.

Capt. William H. Smith will proceed with the least practicable delay to Camp Owenbierne, Texas, and report to the commanding officer for discharge, under the provisions of Circular 75, War Department, 1918.

First Lieut. Carl E. Royer is relieved from his present duties, and will proceed from Ross Field, Arcadia, Cal., to Hazelhurst Field, Mineola, Long Island, N. Y.

First Lieut. Albert C. Adams, unassigned, now at Mitchel Field, Long Island, N. Y., is transferred to United States Army General Hospital No. 43, Hampton, Va., for further observation and treatment.

Second Lieut. Robert Leroy Warfield is announced as on duty requiring him to participate regularly and frequently in aerial flights from November 4, 1918, to December 9, 1918.

First Lieut. John F. Proctor is relieved from his present duties, and will proceed to Rockwell Field, San Diego, Cal., and report in person to the commanding officer for assignment to duty with the 2d Aero Squadron.

First Lieut. Carl L. Kohlmeier is announced as being on duty requiring him to participate regularly and frequently in aerial flights from April 1, 1918 to July 4, 1918.

Second Lieut. Sefus Sutton, Air Service, is relieved from his present assignment and duty, and will proceed to Camp Dix, N. J., and report to the commanding general for assignment to duty.

First Lieut. Roy Robinson is announced on

FOREIGN NEWS

Bossoutrob, French Aviator, Tests Smallest Plane in Existence

A French aviator, Bossoutrob, has made successful experiments with the smallest aeroplane in existence, known as the "mosquito." It has a 20 h.p. engine, and measures 4 yards between the wing tips. It flew for an hour at an altitude of 5,000 feet.

Gathergood Wins London Aerial Derby

London.—The London Aerial Derby, held on June 21, was won by Capt. Gathergood, who made the flight of two circuits of London, aggregating 190 miles in 87 minutes and 45 seconds. His average speed was 140 miles an hour. The best previous time was made by Hamelin in 1913, when he made an average speed of 76 miles an hour. The race has not been contested since 1914.

Captain Gathergood is an experienced pilot, and has made a record in testing machines, having flown, it is said, 87 different types of aeroplanes.

The turning-points and the distances round the course are as follows:

Turning points	Distance From Start. Miles.	Distance From Last Point. Miles.
1. Kempton Park (Waterworks north of railway station)	14	—
2. Epsom (Grand Stand on Race Course)	24	10
3. West Thurrock (Wouldham Cement Works, tall factory chimneys and large shed)	50¼	26¼
4. Epping (Parish Church)	67¾	17½
5. Hertford (large White Cross in Field adjoining railway station, north of town)	78½	10¾
6. The London Aerodrome, Hendon (Starting, *Passing Over* on first circuit, and Finishing at No. 1 Pylon)	94½	16

Aerial Mails to Greece

It has been announced in Athens that the Italian government has informed the Greek government that it will start giving effect to the convention recently signed between the two countries for air mail service. Two aerodromes are to be established, the one at Corfu, the other at Brindisi.

Aerial Defenses of Panama Canal Zone Being Strengthened

The importance of the aerial defenses of the Panama Canal has led to increased construction at France Field. The natural conditions of the terrain in the Canal Zone are decidedly unfavorable to the use of land machines, the heavily wooded and hilly surface of the land makes landings most hazardous.

France Field has been in existence since April, 1918. It is filled in marsh land and has facilities for housing both land and sea planes More hangars and quarters are under construction and room is being made for increased personnel and equipment.

The only Army Aero Squadron on the Zone at the present time, is the 7th Aero Squadron. It is an observation unit consisting, at the time of writing, of but one flight of six De Haviland planes. Before long however flights B and C will be in operation as soon as personnel and material are available. Flight A consists of Lieut. R. V. Blessley, flight commander; Capt. H. W. Holden, senior observer; pilots, Lieuts. S. M. Connel, J. G. Williams, R. D. Knapp, T. A. McArn, W. B. Souza; observers, Lieuts. D. D. Watson, J. E. McCabe, F. N. Stratton, J. F. Whiteley, and M. D. Adams. Both pilots and observers have all had considerable experience in the Air Service having been developed with the development of the Air Service itself. Many have been overseas from three months to a year. Several were attached to the French and British armies.

Single-motored Plane Long Distance Record Held by French

Cables from France announce that the recent non-stop flight made by the French aviators Roget and Coli from Paris to Rabat, Morocco, a distance of 1,116 miles, constitutes a world's record for a single-motored plane, their machine being driven by one 300-horsepower Renault aviation engine. The flight in question was intended as the initial jump of a trans-Atlantic flight, with scheduled stops at Dakar, West Africa, and St. Paul Rocks in the Virgin Island group, and the terminal some point on the Brazilian Coast of South America. In a forced landing near Rabat for fuel rough ground was encountered, the machine wrecked, and the aviators slightly injured.

Handley Page to Operate Buenos Aires-Pernambuco Service

The Handley Page Co., London, England, has secured concessions to operate aeroplanes in Brazil. The concession is for ten years but does not give exclusive monopolies on privileges. It further provides that within two years the Government may demand that the pilots be Brazilian citizens, and that the machines must be registered with the Inspector of Navigation.

The Handley Page Co. will inaugurate an aerial line between Buenos Aires and Pernambuco and will use machines of 3,000 h.p. and capable of transporting 7,700 lbs., at an average speed of 112 kilometers per hour. It is expected that the voyage between Buenos Aires and Pernambuco will be made in three days with stope at Porto Alegre and Rio de Janeiro. The planes will travel by day only and the passenegrs will stop at night in hotels to be operated by the company. It is expected the service will start within six months. The airships will have a capacity for 12 passengers, with baggage, and one ton of freight.

Chair of Aeronautics at London University

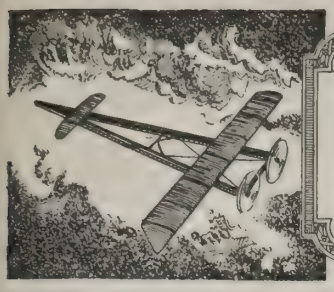
London.—It is announced that a chair of aeronautics has been instituted at London University. It is understood that several of the older universities are contemplating the establishment of a curriculum for aeronautical engineering students, but it remained for London University to initiate the first regular course of study.

Amsterdam Exposition Postponed to August 1st

With further reference to the First Aeronautical Exposition at Amsterdam, which was to have been held during the month of July, and perhaps August, a cable has just been received from Holland stating that this exposition will be held instead, starting August 1, and close some time in September. The cable also states that German participation is excluded and a large English and French participation is expected. It is hoped that America will not remain behind in its exhibits.

The Austin "Greyhound" Aeroplane

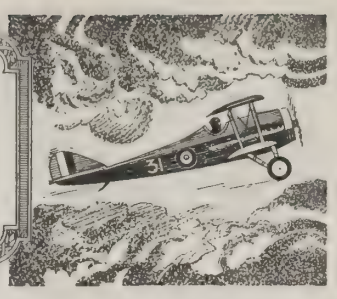
The Austin "Greyhound" is equipped with a nine-cylinder A. B. C. radial engine of 320 h.p. The modification of average practice chiefly noticeable is the difference in size between the upper and lower planes. The top plane has a chord of 6 ft. 4 in., while that of the lower plane is 4 ft. 3 in., dimensions which give a wide field of view, especially for the pilot, the "blind" area being almost negligible. The interplane struts are each made in two pieces with the objects of economizing on timber and preventing the warping of the wood experienced in one-piece struts. The stream-line of the machine is good.



With the object of securing a low landing speed the wings are given a large angle of incidence with the ground on landing.

In a fuel pump of special and novel design all glands are done away with, a positive fuel seal being secured by the aid of an India rubber tube which conveys rotary motion to the pump spindle without itself rotating.

Easy and rapid manufacture has been kept in mind in the design of the machine. Complete dual control has been provided. Two Vickers guns are fixed to fire forward, while a Lewis gun is mounted on a rotating ring on the rear cockpit.



The Austin "Greyhound" two-seater. It has a 9-cylinder 320 H.P. radial A.B.C. engine

ELEMENTARY AERONAUTICS *and* MODEL NOTES

By John F. McMahon

Model Building as a Trade

THE accompanying illustration shows the "Model Department" of the Curtiss Aeroplane Company. This is a part of the experimental department, and the purpose of building these little models is to make a miniature of some large machine for test in a wind tunnel.

As a wind tunnel is not familiar to many people I will describe one before going further. A very complete description of the Curtiss wind tunnel appeared in the June 30th issue of AERIAL AGE.

A wind tunnel is a long tube or funnel, through which is conducted a draft of air, generated by a large fan or propeller and kept in constant motion at a uniform velocity. To keep the air from twisting as would be the case as it leaves the blades of the fan, it is forced through a sort of honeycomb, which looks a good deal like an enlarged automobile radiator, and the air is steadied and continues on without any disturbing motion.

In the centre of this tunnel a special bar hangs from the top. To this bar the model is fastened, and any movement, no matter how small, is registered by instruments attached to the other end of the bar. The resistance of the model as well as the lift of the wings is noted, and from the results shown on the scales, the performance of the big machine can be determined and the designer knows whether or not to change the design.

As this model cannot be larger than three feet spread (this is the largest model most wind tunnels will accommodate) and as some of the larger machines have a spread of 125 feet or more, one can see how accurate the model must be made to get correct results. The tolerance by which the model makers much work is .001 inch and the finish of these models is like that on a high priced piano. These model makers earn large salaries for this work. The government hired hundreds of these titled people during the war to make models for experimental purposes, so the model enthusiasts who follow this page can see what a profitable and interesting art model making is. While the model makers shown in the picture are mostly men of age, there is no age limit or no ban against boys as model makers, as the only thing necessary is to make perfectly accurate models from blue prints and this like all other things must be practised.

The reader can distinguish many well-known machines on the bench and the one nearest looks like a "JENNIE," as our young lieutenants call the JN-4. Many other types of models can be seen, among them the Langley Tandem Monoplane.

Pontoon for Ford Motored Aeroplane

As promised in the last issue of AERIAL AGE I will describe how to build a pontoon for the Ford motored aeroplane recently designed and described by the writer in these columns. This pontoon is constructed in the same fashion as the ordinary "Box-girder" built-up body of an aeroplane (the Curtiss JN for instance), having four main members which are designed as longerons and the cross braces which are called struts. Instead of using wires and turnbuckles to brace the affair, a strut running from one corner of the cross struts to the corner of the one opposite is used.

The general dimensions are 8 feet long, 3 feet wide, and 9 inches deep. The front of bow has what is known as the scow type of entering edge. That is, it does not come to a point, but simply turns up in order to plane on the water. The back is made like the front, only the scow end is reversed. The main longerons are made of 1 inch square ash. The brace struts are made of ¾ inch ash except where the landing chassis struts attach to the float. At this point the struts are 2x1 inch.

The regular landing chassis struts are used with the addition of two or more struts running from the front body connection of the regular struts to the bow of the pontoon. When finished the frame work is covered with three-ply veneer and silk is fastened on with waterproof glue and varnished with a good spar varnish. The wing balancing floats are made of balsa wood and measure 2 feet x 9 inches x 6 inches.

Balsa wood is very light, but not strong. So in order to make it strong enough to stand up under hard usage it will be necessary to bind it with silk and waterproof glue, after which it is sandpapered well and given about five coats of spar varnish. It is necessary to sandpaper each coat before applying the next.

Drawings of this float will appear with the full dimensions and layout in the next issue of AERIAL AGE. We shall then start on the Flying Boat.

An interior view of the model shop at the Curtiss plant. It is in this department that models are made for wind tunnel experiments. About the room may be seen models of the J.N.4; the 18-B Biplane, 18-T Triplane, H-A Hydro, and suspended from the ceiling, the Langley Tandem Monoplane and one of the older model F Flying Boats

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

An Elegy in an Aerodrome

With apologies to Gray

The Verey fires the knell of parting day,
  The whining "Crabbes" flip slowly o'er the 'drome.
The Airman messwards plods his muddy way,
  And leaves the sky to Bristols and to bombs.

Now fade the twinkling hangars from the sight,
  And all the air a solemn silence holds,
Save where the "Camel" wheels his droning flight
  And distant rumblings stir the evening peace.

Save that from yonder camouflaged shed
  The bombers creep upon their nightly strafe,
To fill the Bosche with circumspectly dread
  And watch the movements of his troops upon the Front.

Oft does the flight to Death's dread sickle yield,
  And some brave man spins down to earth,
To crash beneath in some lone field,
  Oft-times to lie unmarked and quite unknown.

Ere long the roar of some twin engine breaks the night,
  As each machine comes down to land;
And so the sleepy pilots, weary from the fight,
  Wend their way to huts and sleep unseen.

—Blip-Switch, *Flight* (London).

The blushing young thing: "Thanks awfully for the flight. Do you know you inspire me with such confidence in the air that I would always trust you."

Aviator: "Is that so? I must take my tailor for a flip."—*Aircraft.*

Dropping a Passenger

Traveler (on the aerial express)—"I want to drop into Hickville, conductor!"

Conductor (looking at watch)—"Strap on your parachute—you walk the plank in seven minutes!"—*Buffalo Express.*

A well-known aviator fell ill and passed away peacefully. "Hullo, Jones," spoke his friend, when the two met in the abode of blues. "How did you get here?"

"Same old way," was the reply—"Flu." —*Aircraft.*

"What did you do in the Greek wars, daddy?"

"I was an aviator, my son. I was the first to fly from Troy when the invaders reached the city."—*Aircraft.*

Up in An Aeroplane

There's a charm fascinating,
That none but we know,
  Up in an aeroplane;
Ozonic elixir sets heart's fire aglow,
Supremely we hover o'er the earth-worms below.
  Up in an aeroplane;
Shrapnel may burst and cannon may roar,
Yet steadily on o'er the battle we soar,
While voices of vengeance are crying encore,
  For the bomb that we launched on the foe.
Then swiftly we turn and are back on our way,
The foe in pursuit, and we've no time to play,—
Death races with us, in a fanciful way,
  But we're ready for aught,—don't you know!

Perchance we are struck,
By a shot from below,
  Up in an aeroplane;
Our exit would quickly be taken, we know,
In defense of the Flag we're ready to go,
  Up in an aeroplane;
A "Devil Ace" moves at bugle's first call,
'Tho' under the wave or sailing o'er all,
He's ready for aught, and whate'er may befall,
  E'er eager to do and to dare.
If death wins, we drop as a meteor shoots,—
Like warriors true, we shall "die in our boots,"
And rest, in the ranks of the silent recruits,
  Till trumpet of Gabriel shall blare.

—*Frederick T. Rudiger.*

The NC-4 is Varnished with Valspar

ONCE more it has been conclusively demonstrated, in the most spectacular flight in history, that Valspar is the *supreme* varnish.

The Navy Department varnished the NC-4 with Valspar because of its absolute *water-proofness*, its unequalled *toughness*, and because it possesses the marvelous *elasticity* required to stand the terrific vibration of a seaplane in flight.

yourselves and the United States naval service."

Admiral Glennon then shook hands with each of the airmen, telling them that they were free to do as they pleased until Monday, when they have to report to Washington for further orders. The officers and crew of the three NC boats then walked to the end of the pier, where their wives and friends were waiting in a room set aside for them. E. H. Howard, former chief machinist's mate of the NC-4, whose hand was cut off by a propeller on the eve of the flight from Rockaway Point, was one of those who greeted the aviators. He told them that he was glad the accident had not happened before it did, for then he would not have had the opportunity of working on the seaplane which made history for this country. Howard, who is regarded as one of the best mechanics in the naval air service, is still under treatment in the hospital.

Wearing the ribbon of the Royal Air Force Cross, which was first awarded to Hawker, and the emblem of the Order of the Tower and Sword, which was bestowed on him by the Portuguese Government, Commander Read talked briefly of the flight to Europe.

"I regret that the operation was not entirely successful," he said. "By that I mean that all of the three seaplanes did not get over. We have had a wonderful reception everywhere, but I am beginning to realize that the receptions are only just starting. If to-day's greeting is to be any criterion it will be a glorious homecoming."

After gathering in the office of Brigadier General G. H. McManusfi where they were congratulated by Colonel Archie Miller, commander of the army aviation field at Mineola, L. I., Colonel Frank Andrews, Inspector General of the Air Service, Captain King Snell, and other representatives of the army's air service, the entire party was taken in automobiles to Manhattan.

The navy's committee of welcome, in addition to Rear Admiral Glennon, included Captain P. Dymington, Lieutenant Commander W. F. Frost, Commander R. W. Cabaniss, in charge of the naval station at Rockaway Point, from which the NC planes started on their flight, and Lieutenant Commander Robert Donohue.

The piers at Hoboken were guarded by four hundred men of Companies C and D of the 13th Infantry, under command of Major Barrett. While the reception to the returning fliers was in progress the soldiers stood at attention along both sides of the pier.

The personnel of the NC-4, which returned on the *Zeppelin*, was as follows: Commanding officer, Lieutenant Commander A. C. Read; pilots, Lieutenant E. F. Stone and Lieutenant W. Hinton; radio operator, Ensign H. C. Rodd; engineer, Chief Special Mechanic E. Rhoades, and reserve pilot, Lieutenant J. L. B. Reese.

The members of the crew of the NC-3 who returned were: Commander J. H. Towers, commanding officer of the squadron; Commander H. C. Richardson, pilot; Lieutenant D. H. McCullogh, pilot; Lieutenant Commander R. A. Lavender, radio operator, and Lieutenant B. Rhoades, reserve pilot.

The officers and crew of the NC-1 were: Lieutenant Commander P. N. L. Bellinger, Lieutenant Commander M. A. Mitscher, pilot; Lieutenant L. T. Barin, pilot; Chief Machinist's Mate C. I. Kesler, engineer, and Machinist R. Christensen, reserve pilot.

Among the invitations extended yesterday to the fliers was one from Glenn H. Curtiss, who asked them to be his guests at a dinner at the Commodore on the evening of July 10. At this dinner Mr. Curtiss will present to the commander of each of the NC boats a model of the plane. Secretary Daniels has promised to attend, and invitations have been sent to the Governor General of Newfoundland, Brigadier General L. E. O. Charlton of the British Air Service, and scientists.

(*Continued from page* 819)

duty requiring him to participate regularly and frequently in aerial flights from March 18, 1918, to June 10, 1918.

The following-named officers will proceed to Fort Sam Houston, Texas, and report in person to the commanding general, Southern Department for assignment to duty: Second Lieut. Ernest M. Allison and Second Lieut. William H. Laughlin.

Second Lieut. Cornelius J. Maguire will proceed to Mineola, Long Island, N. Y., and report in person to the commanding officer, Hazelhurst Field for assignment to duty with the 3d Aero Squadron.

The following-named Air Service first lieutenants will proceed to Palm City, Cal., and report to the commanding general, Camp Hearn for duty with the Eleventh Cavalry: Albert H. Tebo and Hiram E. Wilson.

Second Lieut. Charles L. Webber will proceed to San Diego, Cal., and report in person to the commanding officer, Rockwell Field, for assignment to duty with the 2d Aero Squadron.

Capt. David S. Seaton will proceed to Washington, D. C., and report in person to the Director of Air Service, for duty.

Second Lieut. Thomas H. Marshall is transferred to Army and Navy General Hospital, Hot Springs, Ark., for further treatment.

Lieut. Col. Harry W. Gregg will proceed to Washington, D. C., reporting upon arrival to the Director of Air Service, on temporary duty not to exceed five days, thence to Detroit, Mich., take station there, assume command of the aviation general supply depot.

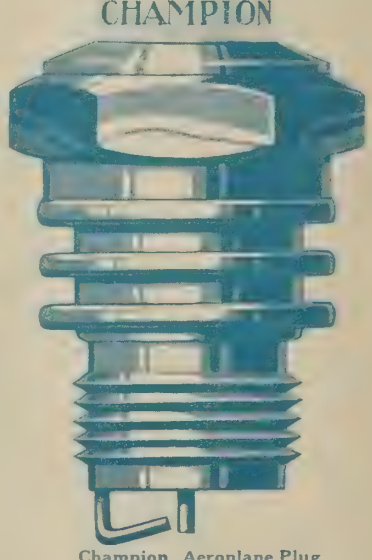
Champion Dependable Spark Plugs



Rigid Inspection Insures Dependability

The success dealers have with Champion Spark Plugs is due in a large measure to the rigid final inspection in our factory.

Long trained experts go over the plugs to make sure that every detail is right, and that there are no imperfections.

This care and thoroughness, coupled with our No. 3450 Champion Insulator and our patented asbestos gasket construction, are responsible for the better performance of Champion spark plugs as compared to other plugs, and their greater resisting power to temperature changes and to shock and vibration.

Insist upon spark plugs with the name "Champion" on the Insulator and the World trade mark on the box.

THE R-34 CROSSES THE ATLANTIC

By HENRY WOODHOUSE

Chairman of the Dirigible Balloon Committee of the Aero Club of America, Vice-President of the Aerial League of America, author of the Textbooks of Military and Navy Aeronautics, etc., etc.

THE crossing of the Atlantic by the R-34 is an epoch making event and a splendid achievement, demonstrating what can be done by dirigibles.

The R-34 was at a disadvantage in this trip because it is the first trip across the Atlantic, and there was no definite meteorologic data available to assist the navigators.

Reading the log of the R-34 is very much like reading the log of an ocean liner, excepting that it was free from rough seas.

Their ability to escape the angry waves and its greater speed are two advantages which airships have over ships of the sea.

Once the air lanes are charted and the prevailing winds are known and suitable arrangements are made to manage the airships on the ground when they land, aerial navigation by airships will be much easier than the navigation of ships at sea.

We must learn to consider ships of the air as we consider ships of the sea. We must learn to operate and moor airships in the air, and only take airships into hangars when it is necessary to make repairs.

Towers and masts are to take the place of hangars for mooring airships, and the hangars will be used essentially as "docks" where airships are repaired.

With dirigibles of close to 3,000,000 cubic feet gas capacity already in operation, and others of 10,000,000 cubic feet capacity being planned, the dirigible looms up as a potential factor in the development of aerial transport.

We have learned a lot about dirigibles during the war, and when what we have learned is put into effect the result will be the operation of large dirigibles capable of carrying 100 tons of useful load each trip and commercially operated and capable of staying in the air for weeks without stopping.

Dirigibles have progressed very rapidly during the past eight years, but their greatest development is to come during the coming three years, when we may expect to see 10,000,000 cubic feet dirigibles capable of a speed of over 100 miles an hour, capable of rising to a height of 30,000 feet when necessary to escape storms or take advantage of trade wind currents.

Great Britain now leads in aeronautics, especially in the construction of dirigibles. She has surpassed Germany.

In the United States we have not yet begun to build large dirigibles, although they are most necessary to our national defenses and would be useful for transportation, to solve difficult problems of transportation.

Prompt Action Necessary

THE United States Army, Navy, the Aero Club of America, the Aerial League of America and civilian aeronautic authorities are anxious to end the ten years spell of national procrastination regarding dirigibles and would like to have the United States purchase the R-34 or its sister airship the R-33 as a model ship to use as a pattern for constructing a larger one in the United States, and as a practice ship for training a nucleus of personnel for a rigid airship service.

The cross Atlantic cruise of the R-34 has vindicated the sponsors of the rigid dirigible who have been urging the construction of rigid airships in this country for the past eight years.

Among the pioneers who urged the United States to build large airships in the United States have been Major Thomas S. Baldwin, who built the first U. S. Army dirigible in 1907 and who has been a persistent advocate of rigids for ten years; Rear Admiral Colby M. Chester, U.S.N., who urged the use of dirigibles for naval operations in 1906, thirteen years ago; Rear Admiral Bradley A. Fiske, U.S.N.; Colonel Charles DeF. Chandler, at present in charge of the Balloon Section, U. S. Army; Colonel Frank P. Lahm, U. S. Army; Colonel H. B. Hersey, U. S. Army; Major J. C. McCoy, U. S. Army; Alan R. Hawley, Augustus Post, Major Albert Bond Lambert, U.S.A., all of whom were pioneers in the development of the science and art of aerostatics, which comprises the dirigibles and captive and free balloons.

The construction of large dirigibles for the Navy was recommended on October 9, 1913, by the first Board of Aeronautics, which was convened by the General Board of the Navy for the purpose of formulating an aeronautic policy for the Navy. This first Board of Aeronautics consisted of Capt. W. Irving Chambers, U.S.N., Aeronautic Expert; Commander C. B. Brittain, U.S.N., Assistant Chief of Bureau of Navigation; Commander S. S. Robinson, U.S.N., Assistant Chief of Bureau of Steam Engineering; Lieut. M. H. Simons, U.S.N., of the Bureau of Ordnance; Naval Constructor H. C. Richardson, U.S.N., Bureau of C. and R.; Lieutenant J. H. Towers, U.S.N.; Aviator First-Lieut. A. A. Cunningham, U.S.M.C.

Similar recommendations were made subsequently by Rear-Admiral Mark L. Bristol, who was Director of Naval Aeronautics; Commander V. D. Herbster, U.S.N., who was Naval Attaché in Berlin; Commander J. C. Hunsaker, U.S.N., and Lieut. A. L. Smith, U. S. Marine Corps, who was Naval Attaché in Paris up to the beginning of the great war.

Major Baldwin, Commander Hunsaker, Commander Herbster and several other authorities actually went to Germany to study the construction of Zeppelins and gathered the knowledge and data required to build large rigid dirigibles.

Subsequently Admiral Sims, Admiral Taylor, and other naval officers and Secretary Daniels himself urged building large rigid dirigibles.

But once more the subject was treated like Mark Twain's weather. "Everybody talks about the weather," said Mark Twain, "but nobody does anything about it."

The Army and Navy authorities, like the civilian aeronautic authorities, now feel that the sure way of bringing this national procrastination to an end is to purchase immediately a large dirigible from Great Britain and use it as a model for the construction of a larger one and to train engineers and experts in this country.

The Army can finish the large hangar under construction at Langley Field by the end of next month to house the R-34 or the R-33, and the Navy is ready to construct a large shed at one of the Naval Stations for future rigids.

All that is required is prompt decision to go ahead.

Heretofore the practice has been to send a commission to Europe to study the subject. When the commission was away the Army and Navy administrations changed, and when the commissions returned their reports were filed away and no action was taken.

It is recommended that from now on the policy be to bring the best dirigibles available to the United States with competent experts if necessary to co-operate with American experts in producing even better dirigibles.

Encouragement should also be given to American firms and inventors to demonstrate the value of their products. A number of original American plans for what seem to be promising dirigibles have gone begging for the past three years. These should be investigated. This is a young science and revolutionary developments are possible. Inventive genius and experiments should be encouraged.

HOW THE R-34 WAS BROUGHT TO THE UNITED STATES BY THE AERO CLUB OF AMERICA AND AERIAL LEAGUE OF AMERICA

HOW the huge British dirigible, the R-34, was brought to the United States by the Aero Club of America and the Aerial League of America, through the generous offer of a very progressive officer of the Aero Club and Aerial League, who guaranteed the expenses of bringing it to the United States, became known to-day through a report made to the Board of Governors of the Aero Club by Mr. Augustus Post, the Secretary of the Club.

The report follows:

To the Board of Governors, Aero Club of America.

Gentlemen:

I herewith submit to the Board the report of the acts which resulted in bringing to the United States the large British dirigible, which is on its way to the United States.

This matter started last winter when Colonel T. E. Gilmore and another prominent British officer called on Messrs. Alan R. Hawley, the President of the Aero Club of America, and Henry Woodhouse, Vice-President of the Aerial League of America, and asked whether the Club and the League could assist in bringing to the United States one of the large British dirigibles, and stated that the greatest obstacle in the way of its coming was the lack of suitable landing place in a popular section of the United States.

It was found that the United States Army and Navy officials were willing to have this dirigible come over, but could not take the initiative in bringing it over. Therefore the assistance of the Aero Club and the Aerial League was enlisted.

As there were not any civilian landing fields available, nothing could be done at the time.

But in April, as soon as the Atlantic City Airport was established, an invitation was sent to the British Air Ministry to send the dirigible over.

The Air Ministry cabled that they were considering the invitation, and their cable was followed by a letter from Brigadier General L. Charlton, British Air Attaché, stationed at Washington, inquiring whether the Club could enter into an agreement with the British Government to supply the landing grounds, 700,000 cubic feet of hydrogen, 6,000 gallons of gasolene, 500 gallons of oil, mooring facilities—including 3,000 bags of sand, 300 men to handle the balloon, and other necessary equipment. He asked how much this would cost and whether the Aero Club of America could contract with the British Government to supply these things at a given price.

As the matter required immediate action and the Club and the Aerial League of America as organizations could not, without first canvassing their membership, assume the huge liability of bringing over this dirigible, which cost $2,900,000, an official of the Aero Club and of the Aerial League arranged to guarantee all the expenses and to supply free of charge all the above mentioned equipment.

It was estimated that the total cost would be about $70,000, excluding the cost of the grounds, and this gentleman stated he would be glad to meet this obligation for the Aero Club of America, the Aerial League of America and affiliated organizations so as to bring this remarkable dirigible to the United States without delay. He also agreed to pay the expenses of entertaining the staff of the dirigible at Atlantic City for fifteen days. General Charlton was advised to this effect, and he called at the Club and had a meeting with Mr. Alan R. Hawley and Mr. Henry Woodhouse, at which they went over every item of this project and a verbal agreement was entered into, which was confirmed in a letter dated April 9 from Colonel E. Gilmore, Assistant British Air Attaché, to Mr. Hawley, which is quoted herewith:

From: British Air Attaché,
Washington, D. C.

To: Alan R. Hawley, Esq.,
President, Aero Club of America,
New York City.

Dear Sir:

Following your conversation with General Charlton a cable embodying your verbal agreement, of which the following is a paraphrase, was forwarded to the Air Ministry:

Begins:—In connection with the proposed visit of a British dirigible the Aero Club of America and affiliated clubs will guarantee all expenses pertaining to hydrogen, oil, petrol, police, labor, housing, subsistance of personnel and mooring ground, requiring in return that airship visit Atlantic City during May, remaining at least fifteen days. If desirable, accommodation as terminus at Atlantic City available all summer. I recommend the visit and consider the terms satisfactory. A guarantee that the State Department will raise no objection will follow. Ends.

Will you kindly be return of post notify that this is satisfactory to you, upon which General Charlton will consider, conditional to a final ratification by the Air Ministry, the terms settled.

(*Signed*) *T. E. Gilmore, Ass't. Air Attaché,*
Washington, D. C.

The agreement was confirmed in the following letter to General Charlton, dated April 15, 1919:

Brigadier General C. E. O. Charlton, D.S.O.,
British Air Attaché,
Department of Military Aeronautics,
Washington, D. C.
My dear General Charlton:

This confirms the acceptance of the terms stated in your letter of April 9, regarding the proposed visit of the British dirigible to Atlantic City during the month of May and, possibly, for all summer.

Please assure your Government of our hearty co-operation in this and in any other matter in which we can assist.

Trusting you will not hesitate to call upon us whenever we can be of assistance in your splendid work, we remain

(*Signed*) *Alan R. Hawley.*

The Atlantic City Aero Club, through its President, Mr. Albert T. Bell, who has been a pioneer worker in aeronautics and arranged for the aviation meet held in Atlantic City in 1910 and also for the Vaniman dirigible projects in 1911, offered its co-operation in arranging for the receiving and mooring the dirigible at the Atlantic City Airport and also co-operated in securing the approval of the Department of State for bringing the dirigible over.

The Department of State answered that it had no objection to the dirigible coming over and that it had submitted the matter to the War and Navy Departments and that neither Department had any objections, but they believed that, whereas the dirigible is an official dirigible of military character, it should land in the United States at an Army or Naval Station.

It was stated that it would also be advisable to secure the approval of the Governor of New Jersey.

The officials of the Aero Club of America, Aerial League of America, and Atlantic City Aero Club, who were co-operating in this matter, agreed that, in view of the fact that the dirigible is a British military dirigible, it would be advisable to have it land at an Army or Naval Station, and that if either the Army or Naval authorities could arrange for it, it would be best to turn over the proposition to them.

Pending the making of such arrangements with either the Army or Navy, the matter was taken up with Hon. Joseph Tumulty, Secretary to President Wilson, and Hon. Walter E. Edge, Governor of New Jersey, and other officials, inviting their co-operation in arranging to have the unanimous official approval to bring the dirigible to the United States.

Mr. Tumulty referred the letter to the Department of State, which assured us of their approval. Governor Edge gave his approval in the following letter to Mr. Bell, President of the Atlantic City Aero Club:

My dear Mr. Bell:

I have yours of the 10th instant, and it gives me pleasure on behalf of New Jersey to second the efforts of the Atlantic City Aero Club and the Aero Club of America to have Atlantic City selected as the landing place for the British dirigibles,

(*Continued on page* 863)

The News of the Week

Aero Club Luncheon to NC Crews July 10

The luncheon planned by the Aero Club of America, in honor of the navy's transatlantic flyers, for July 2, which could not be given on that day because the commanders of the flying boats had to report at Washington, has been set for July 10 at the Waldorf-Astoria. An announcement to that effect was made over the signatures of President Hawley of the Aero Club and H. Pushae Williams, President of the Queensboro Chamber of Commerce.

The Aero Club will present medals to the aviators. Prominent officials of the navy, the army and the Government will be present.

$3,500,000 Expenditure for Naval Dirigible Hangars

Washington, D. C.—Under authority of the Naval Bill, construction on two large dirigible hangars will be begun in the near future. Rear-Admiral Taylor, head of the Bureau of Construction and Repair and Rear-Admiral Parks, Chief of the Bureau of Yards and Docks have been ordered to prepare the plans for the two hangars, which will probably be erected somewhere in the state of New Jersey.

Joseph A. Steinmetz Elected President of Engineers' Club of Philadelphia

Philadelphia, Pa.—Mr. Joseph A. Steinmetz, president of the Aero Club of Pennsylvania, was recently elected president of the Engineers' Club of Philadelphia. Mr. Steinmetz, in addition to belonging to many technical and industrial organizations, including the Aero Club of America, is a member of the firm of Janney, Steinmetz and Co. His election to the new honor has caused a great deal of felicitation and satisfaction among the membership of the club.

Los Angeles to San Diego in 75 Minutes

San Diego, Cal.—Lieut. A. Brokaw, piloting a Spad scout, flew from Los Angeles to San Diego, a distance of 160 miles, in 75 minutes.

Bishop to Preach From Dirigible Car

Columbus, Ohio. — Pending sanction from the War Department, plans are being made by the officials of the Methodist Centenary for a sermon by one of the bishops from the decks of a huge dirigible, the A-4, which has arrived here from Akron. If plans materialize, a bishop will ascend with the four army officers and will deliver his sermon through a large megaphone.

Dr. Helm Buys Curtiss Plane to Cover Professional Rounds

Garden City, L. I.—As a result of the successful use of the aeroplane by Dr. Frank Brewster of Beaver City, Neb., in making professional calls, Dr. W. B. Helm of Rockford, Ill., has ordered a Curtiss biplane. He was a visitor at the Curtiss plant at Garden City recently to look over a plane he expects to use in Illinois. He is one of the best-known surgeons in the middle West. Dr. Brewster recently flew sixty miles to perform an operation, making the trip in fifty minutes. It would have required two and a half hours by automobile and more than four hours by train.

Photograph of the reception and lunch given to the commanders and staff of the NC seaplanes in Paris, by the Foreign Service Committee of the Aero Club of America, on June 12th, at the former Aviation Officers Club. The American Ambassador, Hon. Hugh C. Wallace, as Hon. Chairman of the Aero Club Committee, presided. The following were present: Commanders A. C. Read, Towers, Bellinger; Captain Richardson; Lts. Mitscher, McCulloch, Stone, Barin, Hinton, Breese, Rodd, Christiansen, Thoades and Kessler.

Hon. Hugh C. Wallace, American Ambassador; Sidney B. Veit, Robert Woods Bliss, William S. Hogan, Dr. A. L. Hipwell, Louis D. Beaumont, Frank S. Lahm, Col. Ed. L. Gros, G. F. Campbell Wood, IsaacJones, M.D., Admiral Long, General Foulois, U. S. A. Air Service; Col. Whitehead, Captain Paulding, Secretary American Ambassy; Dr. Lines, President, American Club; Ridgley Carter, Chairman, Paris Section, U. S. Navy League; Mr. Mower, Hon. Secretary, Paris Section, U. S. Navy League; Prof. Mark Baldwin, Former Pres., Paris Section, U. S. Navy League; A. Mascuraud, Member of French Senate; de Saint Blancard, Secretary, Aero Club of France; Mr. de Sillac, Foreign Service; Louis Bleriot, first to cross English Channel in a plane; Lieut. H. Roget, French Army Air Service, who flew from Willacoublay (near Paris) to Rabat (Morocco); Comte de Beaumont, Vice-President, Cercle Interallié; Lieut. de Romanet, French "Ace"; General Harts, Base Commander of Place of Paris; Major Angelo di Nola, Italian Air Service; Comte de la Vaulx, Vice-President, Aero Club de France; Mr. Howard E. Coffin, American Aviation Mission; Mr. S. Bradley, American Aviation Mission; Captain H. C. Mustin, American Aviation Mission; Lieut.-Commander Correy, American Aviation Mission; Mr. Keys, American Aviation Mission; Lt. Wurtz, American Aviation Mission; Lt. Masquielin, American Aviation Mission.

The speakers at the banquet were as follows: Hon. Hugh C. Wallace, Admiral Knapp, U. S. N. Air Service; General Foulois, U. S. A. Air Service; Baron d'Estournelles de Constant, President of the Aviation Commission in the French Senate; Captain de l'Escaille, French Naval Air Service; Deutsch de la Meurthe, President, Aero Club de France; Commander Read, Commander Towers, Mr. Louis Bleriot.

Handley Page Attempts Newfoundland-Atlantic City Flight

The huge Handley Page biplane which has been at Harbor Grace, Newfoundland, for the past few weeks preparatory to a transatlantic flight, attempted a flight from Newfoundland to the Atlantic City Airport on July 5, but was forced to land through engine trouble at Parrsboro, N.S., 525 miles from the starting point. The incomplete reports which are available as we go to press would indicate that the damage done to the machine is so great that it will be unable to proceed to its destination. None of the crew was injured.

Banquet to Commander Read and NC Crews

Lieut. Commander A. C. Read, American naval flyer who crossed the Atlantic in the NC-4, and Commander John H. Towers and Lieut. Commander P. N. L. Bellinger, who also attempted the crossing and made a gallant fight in reaching the Azores, were dined at the Hotel Commodore on July 3.

Commander Read told the people present that the airboats of the future will have to be considerably larger than the NC craft.

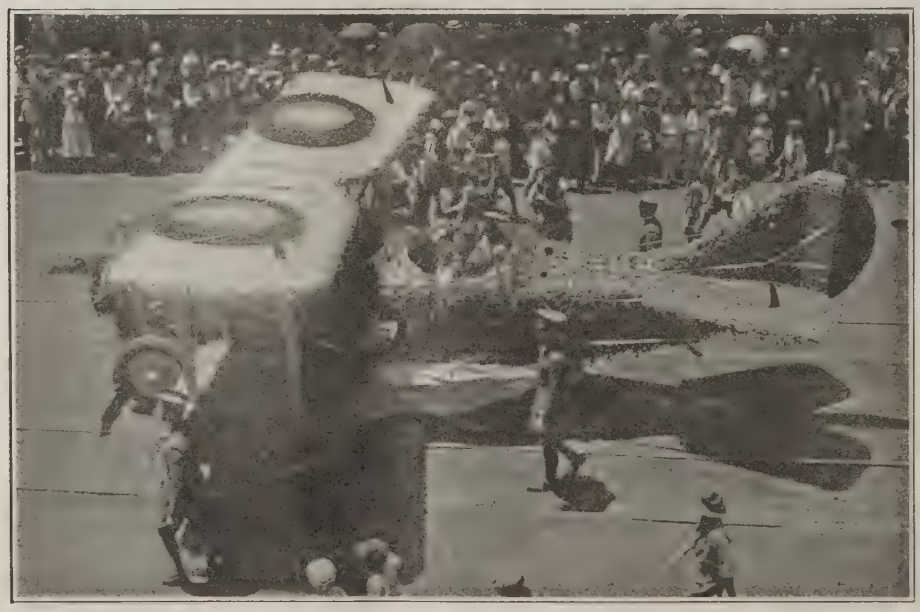
At the guest table besides the aviators were Major Gen. Charles T. Menoher, Chief of the Army Air Service; Rear Admiral James H. Glennon, commandant of the Third Naval District; Commander H. C. Richardson of Commander Towers' crew; Commanders J. C. Hunsaker, G. C. Westervelt, Glenn H. Curtiss, United States Senator New of Indiana, Congressman La Guardia, and Brig. Gen. L. E. O. Charlton, British Air Attaché at Washington.

Army Aviator Elopes in Aeroplane

Hays, Kans.—Lieut. Warren P. Kite, for twenty-two months instructor at Kelly Field, eloped with Miss Orpha Kate Arnold, ranch owner and oil operator of Larned, Kans. After a 55-minute flight, he landed at Hays, where the ceremony took place. Lieut. Kite arrived at Larned nine days previous to the wedding in order to participate in local homecoming celebrations, during which he became acquainted with the bride. Lieut. Kite is from Springfield, Mo., and will make his home there.

Spares Delivered 150 Miles by Plane An Hour After Order

Washington.—A De Haviland-4 aeroplane flew recently from Hazelhurst Field, Mineola, to Albany, with spare parts, to make minor repairs on one of the seven De Haviland planes in the squadron making the Dallas-Boston flight.



Col. H. B. Claggett, commander of the squadron, telephoned Col. Archie Miller, at Hazelhurst, to send up the spare parts. Sixty-five minutes later they arrived. Fifteen minutes were required to make the repairs. Sixty minutes later Lieut. Ralph C. Kilpatrick, pilot, and Major Henry J. E. Miller had returned to Hazelhurst. They made the 220 miles of the round trip in 125 minutes.

Navy Dirigible C-8 Explodes

The U. S. Navy dirigible C-8, sister ship of the C-5, which was blown to sea from St. John's, Newfoundland, some weeks ago, and never heard of again, exploded with great force at Camp Holabird, near Baltimore, Md., on July 1, just after having made a forced landing while on her flight from Cape May, N. J., to Washington. It is uncertain if the sudden heat in the atmosphere to which the ship was subjected when she made her landing, or the careless handling of a cigar or cigarette by some civilian, ignited the gas. A large crowd surrounded the craft at the time of the explosion and several civilians were burned, but none killed. The officers, crew and passengers of the dirigible who escaped injury included Lieut. N. J. Learned, U.S.N.R.F., commanding officer; navigation officer, Lieut. R. I. Weyerbacher, U.S.N.; directional pilot, Ensign C. W. Tyndall; engineer, Warrant Officer B. F. Sherman; Machinist's Mate Kellar and Radio Operator Lynch. The passengers were Lieut. Commander Quigley and Lieut. A. R. Tilburne. A court of inquiry was ordered to determine, if possible, the cause of the explosion.

Lowney's Chocolates Delivered by Air

Boston, Mass.—Deliveries of Lowney's chocolates by aeroplane was inaugurated on June 27, between Boston and Portsmouth, N. H. Circulars were dropped from the plane which was piloted by E. A. Terhune, Jr., general manager of the North Shore Aerial Transportation Co.

Los Angeles "said it with flowers" to Eddie Rickenbacker, on his first visit there after his return from France

Cotton to Be Shipped by Aeroplane From Georgia to Massachusetts Cotton Mill

Air service of the Army has accepted the offer of the Chamber of Commerce of Americus Georgia to furnish a bale of cotton to be transported by aeroplane from Americus to the Merrimac Manufacturing Company at Lowell. Mass., to be manufactured into print cloth of a specially prepared design submitted by the Air Service and to be distributed by aeroplane as a souvenir representing aerial progress in the transportation of raw material from the cotton fields of the south to the factories of the north to be manufactured and distributed as a finished product.

Mayor Perry D. Thompson, of Lowell, has completed arrangements for the reception of the cotton and its manufacture into cloth and President J. E. Hightower, of the Americus Chamber of Commerce, will have it compressed for shipment. Orders have been issued to the commanding officer at Souther Field, Ga., to provide the aeroplane and assign an officer to make the flight and to the Air Service officer of the Northeastern Department at Boston to designate a suitable landing place at Lowell.

It is quite probable a DeHaviland 4 will be used to transport the cotton. Distance via Washington, New York and Boston about eleven hundred miles.

NC-4 to be Placed on Exhibition in New York

Washington, D. C.—Secretary of the Navy Daniels, in response to numerous suggestions, has ordered Rear-Admiral Glennon to make arrangements for exhibiting the NC-4 in Central Park, New York City, for a period of one week, provided City officials approve the plan.

Count di Zopolla, of Italian Air Service, Weds Miss Mortimer

Count Maris di Zopolla, of the Italian Air Service, who took an active part in the air service on the Italian front, married Miss Edith Mortimer, daughter of Mr. and Mrs. Stanley Mortimer.

Aerial Board Created in Canada

An Aerial Board has been created in Canada under an act passed during the present session, with Hon. A. L. Sifton, chairman; General Mewburn and Hon. C. C. Ballantyne representing the militia and naval service departments respectively, as members; Lieut.-Col. C. M. Biggar, vice-chairman, and other members including: Dr. R. M. Coulter, Deputy Postmaster-General; J. A. Wilson, assistant deputy Minister of Naval Affairs, and Edward S. Busby, chief inspector of the Department of Customs and Inland Revenue.

The board will frame regulations regarding civil flying. Present regulations in force were passed under the War Measures Act and will lapse with the declaration of peace. It will supervise all matters connected with aeronautics; the control and management of aircraft necessary for the conduct of the public service; the fixing of routes of travel, etc.

First Flight Over Adirondacks Successful

Lake Placid, N. Y.—In the first aeroplane to fly over the Adirondack Mountains Lieutenants W. R. Taylor and F. Paul Stevens arrived here on July 1, after a 300 mile flight from Mineola to take part in the official homecoming welcome to be extended to its war heroes by Essex County.

Curtiss "Oriole" to be Delivered From Garden City to Denver by Air

In order to facilitate delivery of a Curtiss "Oriole" which he purchased, I. B. Humphreys of Denver, Col., is sending a pilot to New York with the intention of flying the plane to Colorado. A. M. Lendrum, who is an experienced army pilot, is expected to leave New York early next week to make the flight. The "Oriole" is the plane that won the prize for being the first to fly to Atlantic City. This one will be equipped with one of the new Curtiss K-6 150-horsepower motors. It is designed especially for high altitude work.

Bout in An Aeroplane Latest Recruiting Stunt

The recruiting service of the Army has planned a novel stunt in connection with their recruiting campaign. A boxing match aboard an aeroplane will take place over Camp Dix, providing the New Jersey State Boxing Commission enters no objection, though how far above the earth the authority of the commissioners may run is a question.

Lieut. John S. Donaldson, of the First Pursuit Squadron, challenged all comers to meet him with gloves. The challenge was accepted by Lieut. Leroy M. Wightman, a machine gun officer handy with the padded mitts. The boxers will be belted within a tiny ring in the tonneau of a large bombing plane so that there will be no danger of a plunge to earth in case of a knockout. The flying ring will be driven by Sergeant John Moore, and it is planned to have the referee and timers in another plane that will keep alongside the boxers' plane so that they can judge the points and time the rounds.

San Diego to San Francisco Non-Stop Flight in 4½ Hours

Washington, D. C.—Official announcement from the Air Service states that on July 2 two army aeroplanes, a De Haviland 4 and a La Pere fighter covered the 610 miles between San Diego and San Francisco in 272 minutes, at an average of 136 miles an hour. Lieut. John W. Shartnack piloted the La Pere with M. S. E. Barnard as passenger, and Capt. Lowell H. Smith flew the DH-4.

Sales of Surplus Supplies

Washington, D. C.—The Director of Sales announces that on June 20, $3,254,619 had been paid for surplus material from the Department of Military Aeronautics, which cost the War Department $21,700,000. The surplus of November 11 is valued at $85,000,000, of which 26 per cent is sold. For the Bureau of Aircraft Production the figures are as follows: Surplus, Nov. 11, 1918, $62,000,000; value of material sold, $5,400,000; price paid for material sold, $3,317,809; percentage of surplus sold, 9%.

Woman of 80 in Aeroplane Flight

Washington.—Mrs. Martha H. O'Neill, 80 years old, of Gettysburg, Pa., on June 27 experienced the thrills of her first flight in an aeroplane. She had won the right to make this flight by selling the largest number of Victory bonds in the recent campaign in her home town. She was a passenger in an army aeroplane piloted over Gettysburg battlefiebld by Lieut. Fred Nelson of the Aviation Supply Depot staff at Middletown, Pa.

Aeroplane Reconnaisance to Locate Mosquito Breeding Places a Success

One of the novel uses to which the aeroplane is now being put is that of locating pestilential swamps and marshes. The Navy Department reports that Ensign Van Court, of Hampton Roads, recently made a successful trip along the North Carolina coast in the vicinity of Morehead City for the purpose of spying out territory which should be drained or purified.

Ensign Van Court's job particularly is to find the breeding places of mosquitoes, and as those are discovered steps are taken by sanitation engineers for their elimination.

Admiral Sims Predicts Extended Use of Aerial Bombs and Torpedoes in Naval Warfare

New Haven, Conn.—In depicting the naval battle of the future in an address at the alumni banquet of Yale University, Admiral William S. Sims emphasized the importance of aircraft in deciding naval combats.

"Aeroplanes will launch torpedoes that have a range of more than five miles," said Admiral Sims. "Other 'planes will drop bombs of great size, weighing 3,000 pounds, and still others will control by wireless super-torpedoes carrying an explosive charge of more than one ton. Fleet submarines may be present in great numbers, and many automatic mines may be laid in front of the fleets.

"With both commanders determined to fight a decisive action, the issue will be decided in a short time, and the result will be the practical destruction of the defeated fleet."

Chaperones Must Accompany Vassar Girls on Aerial Joy Rides

Poughkeepsie, N. Y.—Because a student at Vassar took a long air ride with a young lieutenant in the U. S. Air Service, the possibilities are that aeroplane joy rides may become prohibited by the social laws of Vassar College. The student's name has been withheld, but because of her exploit the students have considered inserting rules for aeroplaning into the laws, which are made and enforced by the students' association.

An army aviator was flying over the college grounds, and landed in the driving park. He asked one of the students strolling nearby whether she would care to go up with him, and she accepted. It is not yet decided whether this is a violation of the rule against going riding unchaperoned but aviators are advised for the present to use three-passenger planes.

The Bristol Coupé with 264 H.P. Rolls-Royce Engine

BRITISH DIRIGIBLE R-34 SUCCESSFULLY TRANS-NAVIGATES ATLANTIC FROM SCOTLAND TO UNITED STATES

THE British dirigible R-34 arrived at Roosevelt Field, Mineola, L. I., at 8:45 o'clock in the morning of July 6, circled the field three times to make observations, and at 9:21 o'clock the first overseas air pilgrim Major John Edward Maddock Pritchard, landed upon American soil, after a parachute drop of 2,000 feet.

This completed the longest flight in history, the distance covered being 3,200 miles, not counting the mileage forced upon the flyers by adverse winds. The time consumed was a few minutes more than 108 hours. The big airship brought over thirty-one persons, one of whom was a stowaway, and a tortoise shell cat.

The R-34 was built for the British Admiralty at the Airship Works of Wm. Beardmore & Co., Ltd., Inchinnan, Renfrewshire, Scotland. The ship is about 650 ft. long by 80 ft. in diameter, and it has a capacity of more than 2,000,000 cubic feet, with a useful lift of over 30 tons. She is fitted with Sunbeam-Cossack engines and capable of attaining a speed of about 70 miles per hour. The ship's complement numbers about 30.

The R-34 is one of the two largest dirigibles in the world and is about 670 feet long. Although the construction of the two dirigibles had been in progress at Inchinnan, near Glasgow, for months before the end of the war, it was not until last February that the Admiralty admitted that it had plans for airships even larger than the German Zeppelins.

The R-33, equipped as an aerial battle cruiser, had her trial flight about March 1, and her sister craft took to the air a few days later. It was announced on March 22 that the war equipment of the ships would be partly dismantled and that they would be prepared for a flight across the Atlantic.

It is an open secret that the large rigid airships, R-33 and R-34, do not represent the last word of the Admiralty in this branch of aeronautical effort. There are in hand at the present time at least four other rigid airships of greater size than the R-34, representing a distinct step in advance of any already produced, and it is understood that their completion is hoped for by the end of the year.

The secret of successful long distance flying lies mainly in the efficiency and reliability of the engines, which, in the case of the later rigid airships built or building for the Admiralty, are of Sunbeam-Coatalen design. The R-34 is fitted with four 350 "Cossack" type engines, whilst the two others in addition to having a similar number of "Cossack" engines are equipped with two "Maori" engines of 250 h.p. each, making a total of 1,900 h.p. for each airship. Such figures of engine power in comparison with what obtained in the early days of aviation, when perhaps a 20 h.p. engine was the sole unit, are staggering, but it is safe to say that even now the limit of engine power has not been reached. A very high degree of general efficiency and power maintenance over long periods has been attained for some time past by Sunbeam engines, which possess a reputation second to none.

The Sunbeam Maori engine is of the 12 cylinder, 60°, water-cooled, "V" type, rated at 250 h.p. At ground level the b.h.p. at 2,100 r.p.m. is 265 and at 2,200 r.p.m., 280. Bore, 3.93" (100 mm.); stroke, 5.31" (135 mm.). Bore and stroke ratio, 1.08 to 1. The mean effect of pressure in pounds per square inch is 128. Compression ratio, 3.6 to 1.

There are four valves per cylinder, two inlet and two exhaust. Inlet valves have a lift of .3543" and exhaust valves a lift of .3500". The firing order of the cylinders is as follows: 1-5-3-6-2-4.

Either four Siemens or four W.B.G. Magnetos are used. The W.B.G. Magnetos each weigh 19.1 pounds and their speed x engine speed is 1.5. K.L.G. or C.B. spark plugs are used.

Two gear type oil pumps, one centrifugal water pump and one plunger type air pump are provided. Four C.H.B.Z.S. 42 mm. carburetors are used.

The ratio of gear reduction is 2 to 1 in the "Maori" aeroplane engine, and the propeller is run at one-half engine speed, but in the airships R-33 and R-34, the propellers are driven direct.

The engine complete weighs 830 pounds. Fuel is consumed at rate of 139 pints per hour and oil at 6.5 pints per hour.

The overall dimensions of the Sunbeam "Maori" are as follows: Length, 55.11"; width, 35.46"; and height, 33.85".

When the Air Ministry began to discuss the ocean flight it was planned that one of the ships should take a northerly course and the other should proceed to America by swinging to the south. In dismantling the war equipment, however, it was found that there was too much work to do on the R-33 to prepare her for the flight, and it was decided that only the R-34 should be remodeled. In carrying out this plan the Admiralty formally took over the dirigible from the Air Ministry about May 30 and sent her out on a series of practice flights. The ocean flight was held up by the uncertainty preceding the signing of the Peace Treaty, and the airship took a test flight toward Germany.

The length of the vessel is equal to that of a good-sized ocean liner, and she has a beam of seventy-nine feet, making her almost as wide as some of the large ocean-going ships. From the bottom of her lowest gondola to the top of her gasbag is about ninety-two feet. She has five cars, or gondolas, suspended from her framework, and all are connected by an immense platform about 600 feet long.

The officers in charge of the R-34 on its epoch-making journey from Scotland to America

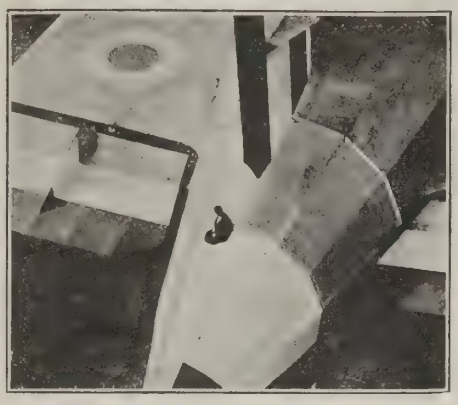
© Keystone

A wireless set in the forward gondola has a range of about 1,500 miles and will be used in enabling the captain to direct his course if the sun and stars are obscured.

The airship weighs about thirty tons, and its useful load is about twenty tons, according to Colonel Lucas. According to the same authority it displaces about sixty tons of air.

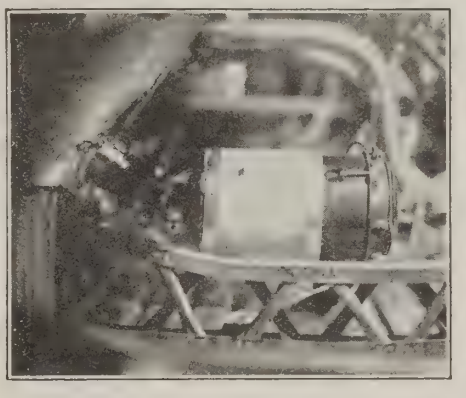
Major G. H. Scott, the commander of the R-34, described the trip as follows:

"The voyage was a very enjoyable and most successful one. The total mileage was 3,200, and we covered that distance in 108 hours and 12 minutes. The thunder squalls we encountered on the way across caused the delay.



"We will leave for home on Tuesday morning about daybreak. We may start around eight o'clock. That is not settled definitely yet, and much depends on the atmospheric conditions.

"We are not certain whether we will go to Washington and Philadelphia, but probably will not. We are planning now to make a flight over New York City before we take out across the ocean. We may go back by way of Boston.



"The return trip, I think will not take more than seventy hours. Of course it will not be so difficult, as we will have the wind with us and probably will meet better weather conditions.

"Coming over we had a crew of thirty men and one stowaway. Not one man suffered any kind of illness. We were all in fine shape when we landed at Roosevelt Field. But we had only enough gasolene to operate a few more hours, and you can see we were very fortunate.

"The stowaway will not make the return trip, but will be left here. He probably will be court-martialed in the near future, but I do not think he will be subjected to any severe punishment. The only change in the crew on the way back home will be the addition of Lieutenant Commander W. A. Henssley, of the United States Naval Air Service, who will take the place of Commander Zachary Lansdowne.

The "crow's nest" of the R-34

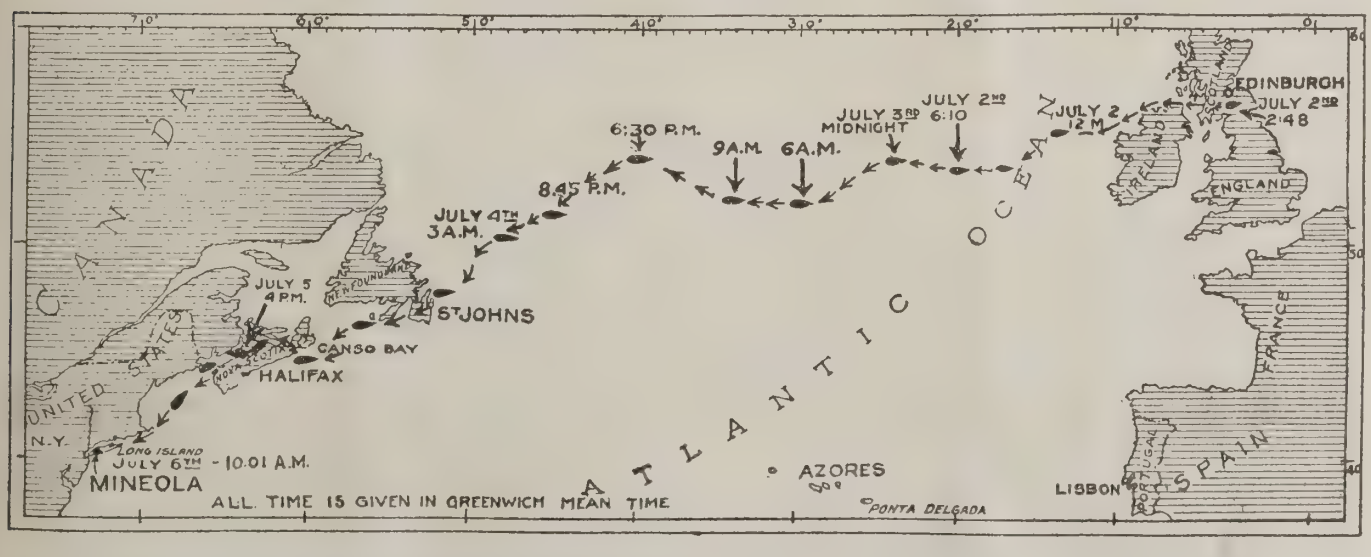
The "cooker" on the R-34, which was used for the preparation of meals en route

"Some of the time we were flying as low as four hundred feet above the ocean. At other times we were as high as 6,000 and 7,000 feet. The altitude varied greatly. All the way over it depended on the wind. We had to keep changing our altitude with the changes in the weather. We encountered strong winds and used five engines, and then at times when the weather was real good we only used two engines. We ran out of gas sooner than we expected because of the strong winds.

"Had the heavy wind over the Bay of Fundy continued through the night we would have been forced to land near Boston. We would not have been able to have made Mineola. The change in the wind came early this morning and it was then that I decided that we could reach Roosevelt Field. I ordered the course changed then.

"We had only four ticklish moments on the way over. Those were during the thunder squalls. They were not serious, however. The only thing that we really feared during the storm was damage to the frame or rudders."

On board the R-34 was a stowaway, formerly one of the crew, who had been dropped a couple of hours before the dirigible left Scotland for the United States. He was found the second day out and had to "work his passage" over.



W. W. Ballantine, the stowaway, had an interesting tale of the trip. He said he lives in Cromwell, and up to two hours before the R-34 left East Fortune, Scotland, he was one of the crew, a rigger. He declared also that a few years ago he was a prize fighter in England.

"I was a rigger on the R-34 and was never more surprised in my life than when I received orders two hours before the dirigible sailed that I was not to be taken along. I was in the rigging when I received the sad news, but I made up my mind then and there that I was going along."

Secretary of the Navy Daniels sent the following message to Major J. H. Scott:

"The American Navy extends its greetings to you and to the heroic crew of the R-34 and congratulates you on the success of your great flight across the ocean. The arrival in America of the first lighter-than-air craft to cross the Atlantic marks another decided advance in navigation of the air. Coming so soon after the flight of Read, Alcock and Hawker, it completes a remarkable series of achievements in aviation in which British and Americans may take a just pride and which have served to increase the cordial relations and comradeship of the two navies which have prevailed throughout the war. America joins with Britain in honoring you and the service you represent.

"JOSEPHUS DANIELS."

The route of the R-34 from East Fortune, Scotland to Mineola, a journey of approximately 3200 miles, made in 108 hours

The AIRCRAFT TRADE REVIEW

Valspar Shipped by Aeroplane

The first shipment of varnish by aeroplane was made on June 26th by Valentine & Co., who sent one hundred cans of Valspar from their Brooklyn factory to C. Y. Schelley & Bro., their local dealer at Allentown, Pa.

The cargo left the field at Long Beach, L. I., at 9.45 a. m. and covered the one hundred miles in seventy-six minutes. This flight was made in a Canadian JN-4, during a steady rain, and with low hanging clouds along the trip. Owing to the necessity of getting the shipment to Allentown in time for a Friday sale, the trip was carried through in spite of the inclement weather.

Lieut. Lyman B. Lockwood and Lieut. Edw. K. Merritt were the pilots on this trip, which was the fourth to Allentown, operated on a regular aerial delivery service between the two cities, by the American & Canadian Allied Flying Circus, Inc., of New York.

The plane was Valsparred the day previous to the flight, and in spite of the steady rain which continued throughout the flight it was in as good condition as when it started.

Mr. Frank P. Connolly, manager of the specialty department of Valentine & Co., who suggested the flight, was highly elated over the record made, and expressed his confidence in the aeroplane as the vehicle of the future for the transportation of merchandise.

Splitdorf Auxiliary Magneto Solved Problem of Starting Liberty Motors

A most picturesque but risky method is ordinarily used to start aeroplane engines. The mechanic shouts "Off!" as he approaches the propeller and is answered in kind by the pilot at the switch. He then spins the great wooden blades by hand to charge the cylinders with gas. Having worked up a warm perspiration, even on the frostiest mornings, he springs clear and shouts "Contact!" The pilot indicates that he has closed the switch by repeating the signal, and the mechanic once more approaches the propeller. With a single swift motion he twirls the blade through an arc of more than 90 degrees and steps quickly away from and to the side of the murderous whirling stick.

A 150-horsepower engine is about all any but a Samson can swing. When heavier engines, culminating in the 400-horsepower Liberty, made their appearance, new methods had to be devised. At first, the blade was pulled over compression, by running past it, giving it a smart pull in passing. Sometimes two men with hands joined were required. As many as three were required to do the preliminary "winding up" or charging. More than one unwary mechanic was sucked into the whirling circle of the propeller and injured before a safer method was devised.

Owing to their weight and complication, electric starters were not considered seriously, but an ingenious auxiliary magneto was contrived by the Splitdorf Electrical Co. of Newark, N. J. This magneto was operated by a small hand crank in the pilot's cockpit. The engine was charged in the usual way, whereupon the mechanic stepped back, shouting "Clear!" The pilot then closed the switch and turned the crank of the starting magneto a few times. The supercharged cylinders received a shower of white-hot sparks and failure to start at a lively clip was exceptional. With the Dixie starting magneto a lone pilot might start a 400-horsepower engine unaided, a thing previously impossible.

Richard H. Depew, Jr., formerly Captain, Air Service, is in charge of enrollment at the Curtiss Flying School

Will Not Restrain Aeroplane Sales

Federal Judge A. N. Hand has denied the motion of the Curtiss Aeroplane and Motor Corporation for a preliminary injunction restraining the United Aircraft Engineering Corporation from continuing an alleged infringement of fourteen patents covering the JN-4 aeroplanes. After the war the defendant bought from the British the aeroplanes and motors and is now selling them in the United States. In his opinion Judge Hand said that a patentee selling his patented article in a foreign country cannot afterward claim an infringement of the patent in the United States, if the article is brought here unless a clause appears in the contract prohibiting export to this country.

Bosch Magnetos at Indianapolis

Indianapolis, Ind.—The success of Bosch magnetos at the Victory Sweepstakes at Indianapolis is another proud record to the credit of the Bosch Company, makers of automobile and aeroplane magnetos. Not only was first, second and third place won by Bosch equipped cars, but of the thirty-three cars which started in this race twenty-two of the world's greatest drivers chose Bosch magneto ignition, and it is a matter of official record that there was not a single ignition adjustment of any kind made during the whole race on any of these twenty-two cars.

Curtiss Aviation School Opens

This week will mark the opening of the Curtiss Aviation School at Garden City, L. I., under the direction of Roland Rohlfs, test pilot for the Curtiss Engineering Corporation, and Richard H. Depew, until recently a captain in the United States Air Service.

More than 200 applications have been received from all parts of the United States, as well as Canada, Mexico, Argentine, Cuba and Italy. The first student to enroll in the school is Alberto Chiesa of Milan, Italy, who has come to America to receive instruction in flying.

Rohlfs, who has been instructor and test pilot for the Curtiss Company, has had more than 2,000 hours in the air, and during his career as a flier he has flown all the Curtiss models—both land and water—including the new three-passenger Oriole, the record-breaking Model 18-T triplane which was designed especially for war purposes and which has since been modified for peace-time flying, and the new Curtiss mail machines.

Depew, who was a flier for the Curtiss Company before the war broke out, was a test pilot at McCook Field, Dayton, O., while in the Air Service of the U. S. Army.

The course to be offered will differ from the methods used by the army. Instead of the three-months' ground school course, followed by several weeks of actual flight, it is the aim of the instructors to teach the principles governing flight simultaneously with actual flying. The course will include lectures on aerodynamics, theory of flight, construction and repair of aeroplanes and motors. Following the lecture, the student will be taken up into the air and taught to apply his theories.

The America Trans-Oceanic Company, distributers for New York and Florida, will operate a water-flying school at Port Washington, L. I. The Curtiss Flying Station at Atlantic City will operate both land and water schools, as will the Curtiss Eastern Airplane Company, distributers for Pennsylvania, Maryland and Delaware. The Curtiss Airplane Company of New England, with headquarters at Boston, will operate schools; also the Curtiss Southwest Airplane Company at Tulsa, Okla., and the Curtiss Northwest Airplane Company at Minneapolis. I. B. Humphreys, distributer for Colorado, will operate a land school, and Sydney Chaplin, brother of the motion picture star, and distributer for southern California and Arizona, will operate schools in California at the Catalina Islands. George W. Browne of Chicago, distributer for the Middle West, will start a school under the direction of Lee Hammond, who conducted experiments for the Navy in flying land machines from the decks of battleships.

Major J. E. H. Stevenot has left for the Philippine Islands to open a school.

In addition to these, many individuals who saw service during the war are starting schools, and, judging by the amount of interest shown, flying will soon be a more or less commonplace accomplishment.

Many schools are also taking up aviation. The Junior Plattsburg camp will inaugurate a course of instruction in aeronautics and Castle Girls' School at Tarrytown-on-Hudson will offer a course in aeroplane mechanics for girls this summer. The Sheffield Scientific School has a course in military aeronautics and many other universities are following the lead.

New York-Chicago Aerial Mail Started

Washington, D. C.—The Air Mail Route between New York and Chicago was inaugurated on July 1, according to an announcement by Second Assistant Postmaster General Praeger, when the Eastern half of the route between New York and Cleveland was linked up with the Western half from Cleveland to Chicago which has been in regular operation since May 15.

A fast flight was made today from New York to Cleveland at the average speed of 110 miles per hour—a distance of 430 miles. A new fast plane left New York at 5:15 a. m. and flew to Bellefonte, Pa., the first stop, at the rate of 123 miles per hour. Another plane took the mail from there to Cleveland at the rate of 100 miles per hour arriving at 9:30 a. m., Eastern time. The entire distance between New York and Chicago is about 750 miles.

Mail can now be sent by aeroplane from New York, leaving there about 5 a. m., and reaching Chicago about 1 p. m. Planes are changed at Bellefonte, Pa. and Cleveland. The air mail arrives in Cleveland in time to catch the plane leaving there at 9:30 a. m. for a non-stop flight to Chicago. About 12,000 letters a day are taken for Pacific Coast points, and through air mail service from New York to Chicago will advance the delivery of mail for Seattle, San Francisco, Los Angeles and other cities about 24 hours sooner than if sent from New York through by mail. This applies to letters received in New York post office for the 8:40 p. m. train westward.

Air mail from the West for New York and points East is taken on at Chicago and Cleveland. A plane leaves Chicago at 2:30 p. m., arriving at Cleveland at 5:30 p. m. in time to connect with the 20th Century Limited, and the mail arrives in New York about 9:00 o'clock the next morning. This gives the business men about three hours more to dispatch mail from Chicago than if sent by train about noon. An aeroplane leaves Cleveland in the morning at 8:30, taking on all air mail from train connections, and the mail arrives in New York about 1:00 p. m., a stop being made at Bellefonte, Pa., to change planes. This also gives the business men a late night service by train to Cleveland connecting with the morning plane at that point for New York and points East, and advancing mail delivery many hours over that by through train service.

Most of the planes used are remodelled De Haviland fours with Liberty motors. They have a capacity of 400 pounds of mail.

Demonstrations in dropping from aeroplanes in parachutes were given at the College Park Air Mail Field, Washington, this afternoon by Mr. William Linley and Miss Sylva Boyden, the English aviatrix, representing two parachute concerns. The purpose of these demonstrations is to determine their practicability for use in protecting mail pilots in cross country flying in case of fire or other accidents which might make a landing by the plane impossible.

Plaut Merchandise Plane Carries Mail

Newark, N. J.—In connection with the aerial delivery service maintained by the L. S. Plaut Co., between Newark, Asbury Park and intermediate points, official sanction was obtained for carrying aerial mail for the Post Office Department. Two Whitteman-Lewis planes, one a land and the other a seaplane are used in the delivery service to the coastal resorts.

Large Sales of Surplus Aircraft Material

Washington, D. C.—According to an announcement from the Office of the Director of Sales, the sale of surplus war materials for the week ending June 20 for the Bureau of Aircraft Production amounted to $274,563.22. The total sales by the War Department from January 1 to June 20 amounted to $333,712,636.75, representing 79 per cent. of the cost of the original material to the Government.

AIRCRAFT RADIO DIRECTION FINDING EQUIPMENT DEVELOPED BY THE NAVY DEPARTMENT

By EDGAR H. FELIX, A., I. R. E.
Formerly Radio Engineer, Signal Corps, U. S. A.

RADIO compass guidance was employed by the NC planes during the trans-Atlantic flight, bearings being taken from a series of destroyers stationed at pre-determined fixed intervals along the route. The instruments used are the result of a great deal of intensive development work on the part of the radio engineers and workers of the Bureau of Steam Engineering of the Navy Department and the results obtained on the flight are evidence of the successful solution of many of the problems of the designs of the radio compass.

Fig. 1. The loop antenna used aboard flying boats and dirigibles

The importance of radio direction finding aboard large aircraft focused the attention of research engineers upon the solution of this problem early in the war. The possibility of overcoming the shortcomings of navigation instruments and calculations as adapted to aerial navigation, by means of the radio compass made this field of research a promising one.

But considerable modification and improvement of direction finding equipment as known prior to 1914 was necessary before it was possible to safely guide home the long distance bombing squadrons by radio after raids over enemy country. The pioneer permanent land station direction finders, as first developed by Bellini and Tossi, of Italy, involved the use of four antennae radiating in four directions 90 degrees apart from the receiving station at their center. Maximum receiving energy was obtained on the antenna which pointed toward the particular transmitting station being plotted, and if the station lay midway or between the direction of two antennae, the proportion of energy received on the two nearest antennae determined roughly the direction of the station being read.

By the use of two such stations at a considerable distance apart, the location of the ship, acting as the transmitting station could be plotted. Such a system is not accurate, and considerable communication between the transmitting station and the two direction finding stations is necessary.

The installation of four antennæ aboard ships, with the purpose of plotting the direction of two known land stations and determining position by triangulation makes intercommunication unnecessary. The only condition is that the identity and position of the stations on which bearings are taken are known.

Owing to conditions of interference existing in the region of the battle lines and the obvious undesirability of transmitting from a plane in flight over the enemy's lines, making it possible for the enemy by means of their own direction finding equipment to determine the position of the hostile plane over their lines, made the advantage of placing the direction-finding equipment on board the aeroplane so clear that the much more difficult problem of developing a radio compass for installation on board the aeroplane was successfully accomplished.

The use of four antennæ erected at angles of 90 degrees from each other aboard an aeroplane is obviously impractical. Therefore, a loop antenna, consisting of several turns of wire mounted on a frame about a yard square, capable of being revolved in any direction, was first used.

Let us consider the effect the incoming electromagnetic waves have on the receiving loop pointed at various angles from the transmitting station.

By means of a well-known analogy, it is easier to visualize the effect. When a large stone is thrown into a still pond waves radiate in all directions from the point at which the stone entered the water. This corresponds to the transmitting station. At some distance from that point, a stick is floating on the water, at the center of which there is placed a level balance. This represents the radio receiving station. If the stick is pointing toward the "transmitting station," the balance will be set into maximum oscillation by the wave motion imparted to the stick. If the stick, however, is at right angles to the direction of propagation of the waves, although the stick will move up and down, there will be no end to end motion, and the balance will not be affected. The direction which the stick is pointing will determine the strength of the oscillations imparted to the balance, and if the stick can be turned to point at will, the direction from which the waves come can be determined.

In the case of the loop antenna, the electromagnetic waves of the ether will set up electrical oscillations in the loop, if it is so placed that there is a difference of potential between one part of the loop and the other. These are detected by the receiving equipment and the operator, by turning the loop until maximum intensity of signal is obtained, can determine the direction of propagation of the waves.

The curve on Figure 2 shows the amount of energy

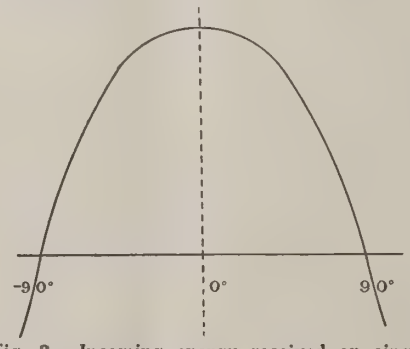

Fig. 2. Incoming energy received on single loop through rotation of 360 degrees

received on the loop at all angles relative to the direction of wave propagation. It will be noted that the curve is a gradual one, and that there is no marked maximum. Therefore, the accuracy of the reading, even with the finest discrimination of a trained ear under condition of absolute quiet, does not reveal within more than 10 degrees the direction of the transmitter. With the loud motor and wind noises and electrical interference due to the ignition system present aboard aircraft in flight, such direction finding equipment is of no practical value.

To overcome these difficulties, the "balanced maximum" method was devised. The following statement of the theory of that system is taken from a paper on "Naval Aircraft Radio" delivered by T. Johnson, Jr., expert radio aide, Navy Department, delivered before the Institute of Radio Engineers at New York on June 4th:

"Referring to Figure 3, if 'ABC' represent a curve of strength of signal as a coil is rotated through 180 degrees

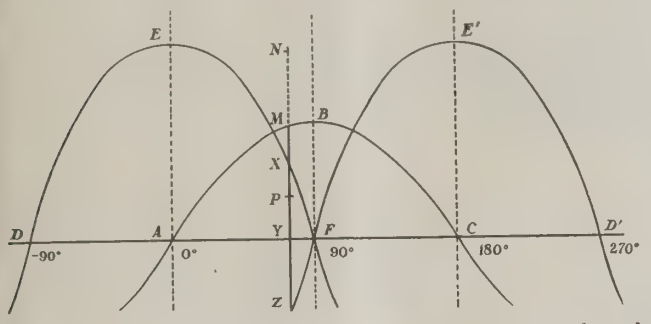

Fig. 3. Incoming energy on two loops 90 degrees apart through rotation of 360 degrees

in a field of radio signals, it will be seen that the maximum is quite flat and could not be detected by the ear within very wide limits. Now let 'DEF' represent the curve of strength of signal for a coil 90 degrees from 'ABC,' or a right-angle coil. When the 'ABC' coil is at some angle, 'OY,' it will have a strength of signal 'YM,' and 'DEF' coil will have a strength of signal 'YX.' Then if the signals 'YM' and 'YX' are added there will be a resultant strength of signal 'YN,' and if they are opposed there will be a resultant strength of signal 'YP.' In other words, if the 'DEF' coil is connected in series with the 'ABC' coil by means of a reversing switch, it can be made to add or oppose its strength of signal to that of the 'ABC' coil. The reversal of the 'DEF' coil is equivalent to advancing its angular position 180 degrees and its curve of signal strength becomes 'FE^{1}D^1.' Then when the 'ABC' coil is at an angle 'OY,' the 'DEF' coil signal strength, 'YZ', is negative, and opposes that of the 'ABC' coil. Thus, when the reversing switch is moved back and forth with the 'ABC' coil at an angle 'OY',' the resultant signal strength alternates in value from 'YP' to 'YN,' to total difference of 'PN,' which is decidedly noticeable. When the 'ABC' coil is at the 90-degree position, the 'DEF' coil has zero strength of signal and no variation in resultant signal strength is obtained by operating the reversing switch. A very sharp point of reference is thus obtained as from Figure 3, it will be noted that as the 'ABC' coil approaches the 90-degree position, there is a large change in value of the 'DEF' coil signal strength for a small change in angle, and this change in signal strength is doubled by the reversing of connection."

Highly accurate readings have been made by the use of properly designed instruments using this method of determination. There is no danger of mistaking cessation of transmission for the minimum signal strength point, and the body of the signal at all points of adjustment is sufficiently strong to overcome the aeroplane noises.

The equipment required to add this type of radio compass aboard a plane after regular receiving equipment has been installed is simple. For this purpose a small control panel, known as type SE 1441-A, was designed, which, together with the antenna loops, is all that is required. In the illustration one of the variable condensers on the panel compensates for the capacity of the auxiliary loop, the other condenser being used to tune the loop to the incoming signals. The reversing switch below the two condenser knobs permits easy change of the auxiliary loop connections until zero signal variation is obtained.

The construction of the revolving coils used on naval aeroplanes is shown in Figure 1. These coils are mounted in the body of the fuselage of flying boats or in the car of the dirigibles. Each set of coils is divided into two equal sections connected in parallel. The illustration shows the type of coil used on the F-5-L boats. The coils revolve in

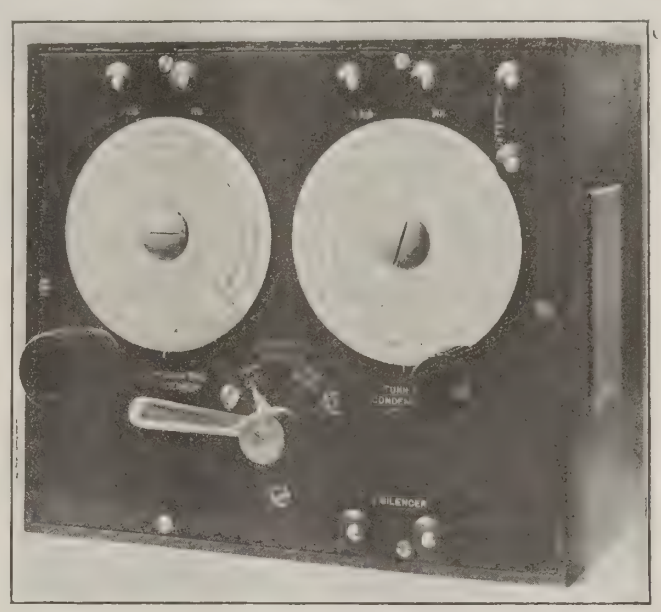

Photo by courtesy of Institute of Radio Engineers

Fig. 4. Type SE 1441-A, for controlling the radio compass

a diameter of 34 inches and stand 34 inches high. The loops used on the NC boats and the C-type dirigibles are forty inches square. The wire used is number 18 B. and S. gauge enameled copper. The ratio of turns on the auxiliary coil to those on the main coil is about two to one.

With the standard SE-950 vacuum tube receiving set and the loops described, accurate readings have been made from the Arlington station at a distance of 300 nautical miles. In a series of tests at Hampton Roads taken with the flying boat at rest on the water, five readings made on the spark station at Swan Island, West Indies, 1,200 nautical miles (2,200 kilometers) distant, were all within 2 degrees correct.

With the advent of the silent aeroplane and more comfortable quarters for the radio operator, more perfect cooperation and organization with beacon stations, and equipment of the type already designed, it is a certainty that the radio compass will be sufficiently developed to guide transatlantic air cruisers to port with the same accuracy and certainty with which navigating instruments now guide ocean liners to port.

ACADEMY OF APPLIED AERONAUTICS OFFERS AERONAUTICAL ENGINEERING COURSES

Chicago, Ill.—The Academy of Applied Aeronautics has outlined a series of very excellent and comprehensive courses, which will be given in a two months' summer school course. The school is located in a four-story fireproof structure with light, airy classrooms, recreation quarters, library, reading and smoking rooms, conveniently located on Lake Michigan, for direct transportation to all parts of Chicago.

The courses offered, embracing the subjects necessary for the Degree of Aeronautical Engineer, are as follows:

Aerodynamics: Development of theory of flight; action of forces on surfaces; laboratory experiments on aerodynamic laws; aerography; present status of aerodynamic research.

Rigging: Principles and details of construction; modern types of aircraft; use and adaptability of different types for commercial purposes; latest improvements in design.

Motors: Principles and operation of internal combustion motors; laboratory work in functions of various types; comparative efficiency of all well-known types; adaptability of different types for use in passenger, freight, or pleasure craft over land or water.

Navigation: Construction of maps by triangulation; charts of the course; meteorological conditions; instruments and their uses.

Photography: Aeronautical cameras; aerial surveying and map making from photographs.

Radio: Use of wireless in communication between land stations and ships in the air.

Economic: Cost of construction; cost of operation, including maintenance and depreciation; comparative costs per hour for different classes of service; overhead and fixed expense.

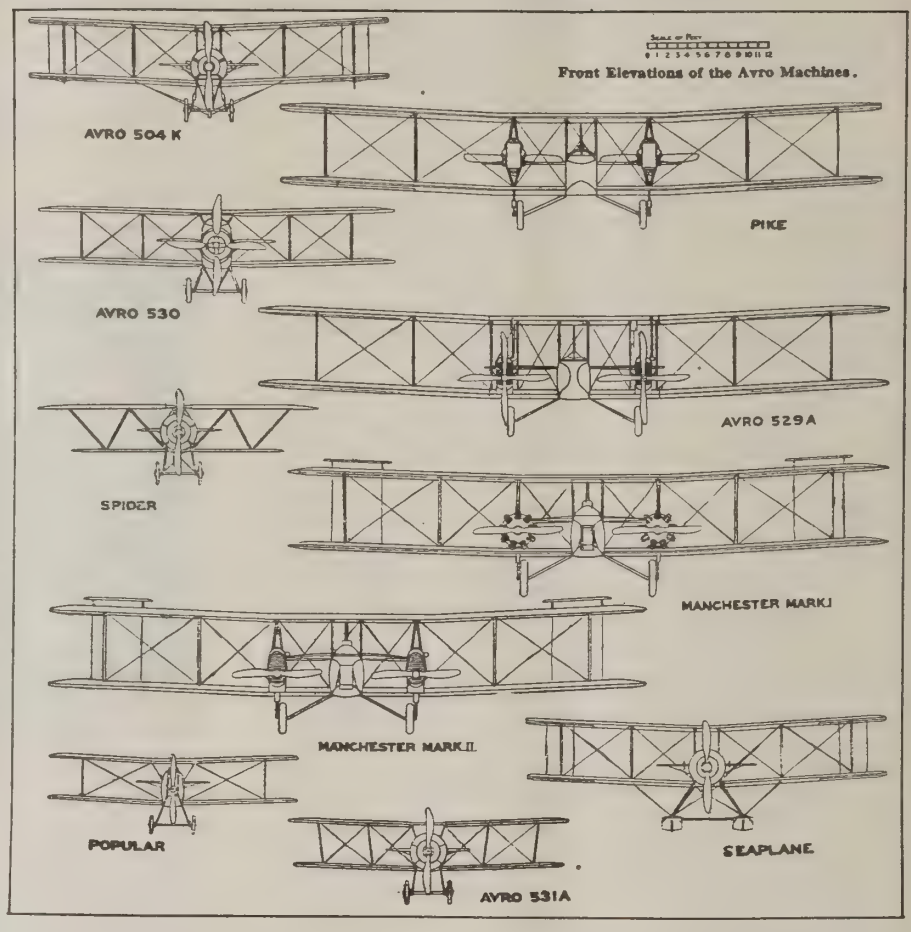
The duration of the complete course is nine months. The fee is $250. Students who can show that they are proficient in certain subjects will not be required to remain with the school the entire nine months. In such cases arrangements may be made in regard to subjects and terms.

Pilots: Arrangements are also being made for students who desire to participate in flights. These flights will be conducted under the supervision of skilled and highly trained pilots. "Stunt" or dangerous flying is forbidden.

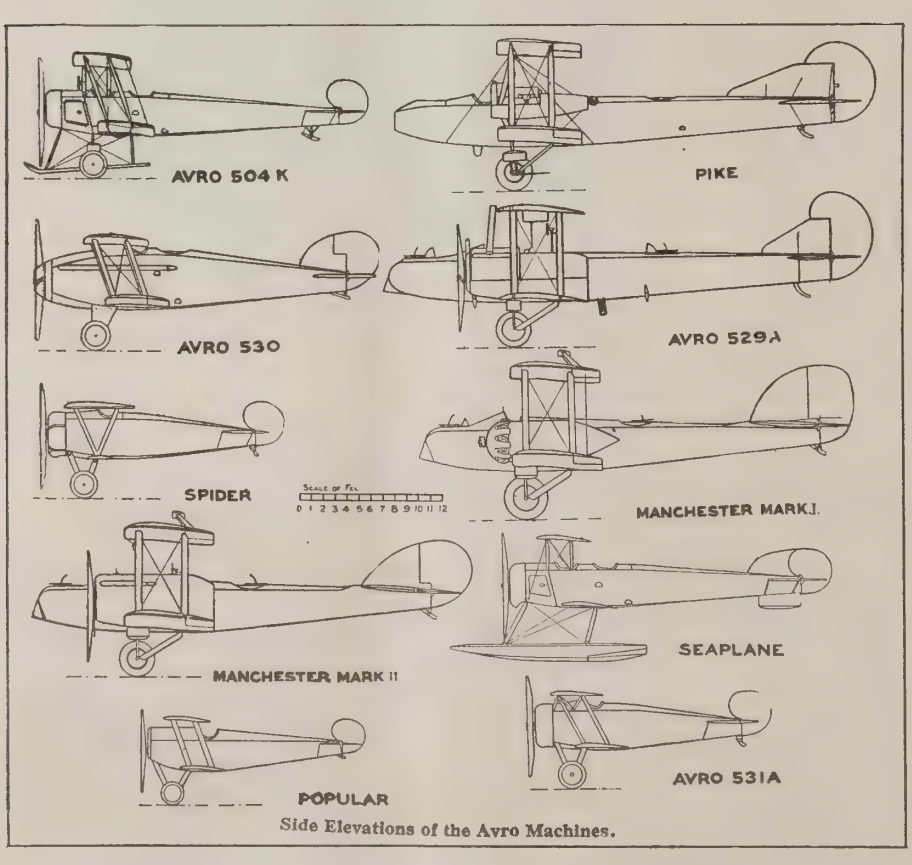
THE BRITISH AVRO AEROPLANES

The Avro Aeroplanes

SOME of the aeroplanes built by the British Avro Company since 1914, and described in "Flight," show the wide range in design and the many purposes for which these machines have been used with success.



The Type 504 K Training Machine



The modern version of the original 1913 type is known as the 504 K, and is to all intents and purposes identical with the original. It has been strengthened up in places, it is true, and minor alterations made, but fundamentally the design remains unaltered. Of the alterations made, mention may be made of the engine mounting, which was, in the older machine, of the two-bearer type, the front bearer being in the form of a ball race supported on four tubular arms forming extensions of the fuselage longerons. This "spider," as it is usually termed, has been removed in the type 504 K, and the engine is supported on two bearer plates behind the crank case—in other words, is overhung. Also the power has been increased from that of the original 80 H.P. Gnome to more modern rotaries, such as the 100 H.P. Gnome monosoupape or the 110 H.P. Le Rhone. In the table of performances printed elsewhere the figures relating to the 504 K represent the performance of the machine when fitted with a 110-H.P. Le Rhone. Any standard rotary engine up to about 100 H.P. can be fitted without entailing any alteration in the machine, adapters being supplied to suit all engines. The A.B.C. Wasp can also be fitted if desired.

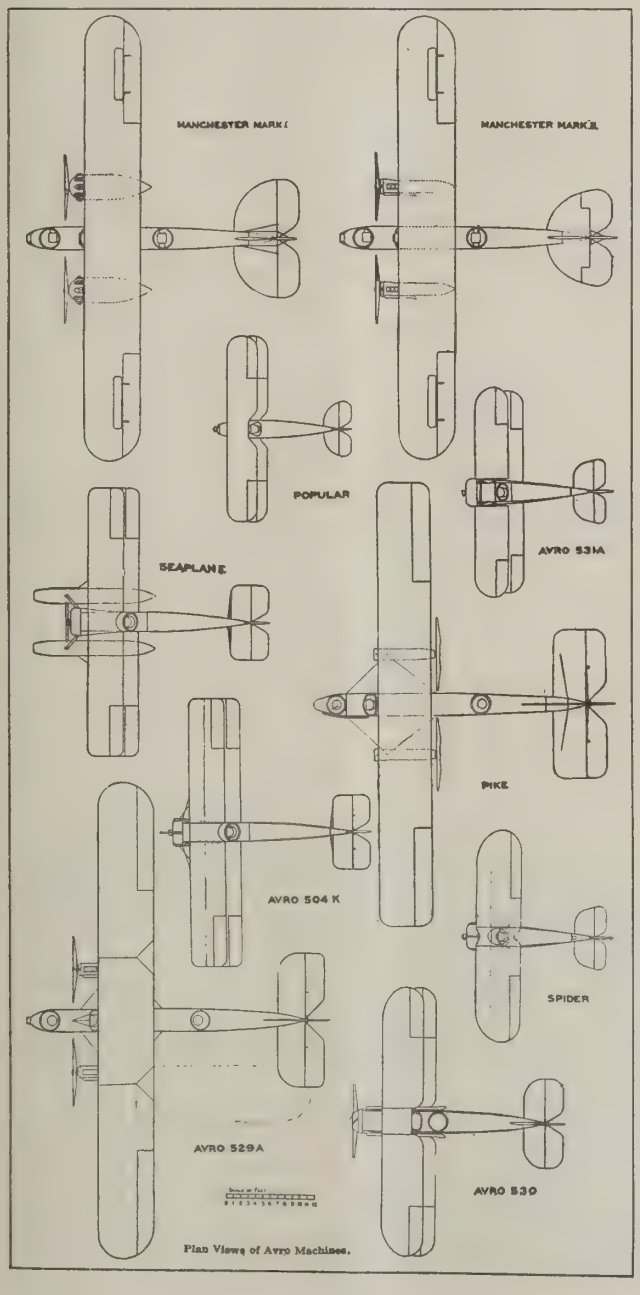
Pilots who have flown the Avro 504 K all agree that it is an extremely comfortable machine, and that on it it is possible to do every kind of "stunt" imaginable. The machine appears to be extremely strong in spite of its light weight, and is so easy on the controls that it is not in the least surprising to learn that it has been adopted as the standard training machine for the Royal Air Force. In this capacity it has been built in huge numbers, and it is even probable that more machines of this type have been built than of any other type in the world.

As an inexpensive touring machine for the owner-driver after the war this machine should have much to recommend it, since, even when fitted with an engine of 80 H.P. only, it has a very good performance, and the first cost, as well as the running cost, would not then be unreasonably great. As a matter of fact, we believe that the type is now undergoing further development, and that it is about to be issued in a slightly new form, probably to be known as the 504 M, in which it is arranged as a three-seater, with an enclosed cabin for the pilot and two passengers. This, however, is still a thing of the future, and no particulars can, therefore, be given at present.

It may be remembered that in 1914 the Avro firm got out a tractor seaplane, 150 H.P. Sunbeam engine, for the circuit of Britain. Although the outbreak of war prevented the running of this race, this particular type of machine was proceeded with, and several were built early in 1915. The time between the outbreak of hos-

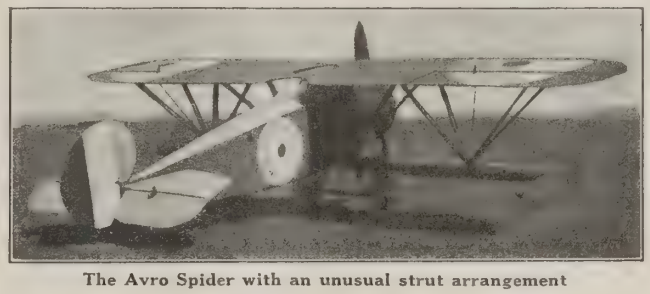
Side Elevations of the Avro Machines.

tilities and May, 1916, was taken up with the construction, in addition to the standard 504, of 130-H.P. Clerget two-seaters, 130-H.P. Sunbeam two-seaters seaplanes, and several large single-engined bombers. The 504 was slightly altered in various respects for different jobs. Then in May, 1916, tests were carried out on a twin-engined bomber.



The Avro "Pike"

This machine was the first Avro twin-engined machine to be built, and was intended for work as a three-seater fighter. The general arrangement will be clear from the accompanying diagrams. The pilot occupied the middle seat, while a gunner was placed in the nose of the fuselage, and one well aft, about halfway between the planes and the tail. From the tables it will be seen that the "Pike" had a very good performance, considering that she only had a total horsepower of 320, the power plant consisting of two Sunbeam engines each of 160 H.P. In plan the machine was very similar to the standard single-engined Avros, with rectangular planes and tail, with the corners rounded off. The machine had an adjustable tail, rotatable gun rings, and bomb racks. The pusher airscrews were carried on extension shafts from the engines, and rotated in opposite directions. Considering the time of testing the first machine, May, 1916, and the good performance for its power, it is not immediately obvious why the type was not at once put into production, but the fact remains that it was not, immediately or at any time. The solution does not emerge from the table of performances, which would certainly appear to justify its production in quantities.



The Avro Manchester, Mark II, with two 250 H.P. Siddeley "Puna" Engines

Contemporary with the "Pike," another machine, which was really her sister 'plane, was going through the works. This machine was, however, fitted with two Green engines of 150 H.P. each. Also the airscrews were tractors instead of pushers. This machine was tested in August, 1916. A third machine on very similar lines, but totally different in detail design, was fitted with two Rolls-Royce engines of 190 H.P. each. This was known as the 520 type, and was first tested in April, 1917.

Plan Views of Avro Machines.

The Avro Spider with an unusual strut arrangement

Avro Two-Seater Fighter, Type 530

In many ways the 530, built in July, 1917, was a radical departure from usual Avro practice. Thus the engine, instead of the rotaries fitted in the type 504 machines, was a water-cooled—a 200-H.P. Sunbeam "Arab." Also the shape of the wing tips was totally different from the usual Avro rectangular tips with rounded corners. As regards the fuselage, this was very much deeper, and of different shape altogether from the ordinary Avro bodies. The object kept in view when designing this machine was to provide as good a view as possible for both gunner and pilot. To this end the body was made very deep, and the pilot was so placed that his eyes were on a level with the under side of the top plane. Similarly the gunner was placed very high in relation to the top plane, being, in fact, able to fire over it. It will be noticed that the attachment of the top plane to the body was unusual. A sort of fin was extended up from the body, covered with

The Avro Seaplane Type 504 L

Avro Aeroplanes—The machine at the left is the Avro "Pike" with two 160 H.P. Sunbeam Engines. The machine at the right is a sister plane to the "Pike", but is fitted with two 150 H.P. Green Engines

ply-wood, to which the center section was attached. Inside this fin was mounted the pilot's machine gun, synchronized, of course, while the gunner's weapon was mounted on the usual rotatable gun ring. The undercarriage was of a simple Vee type, but forming a letter M, as seen from in front, and the two side Vees were enclosed in fabric. The machine was very light and quick on the controls, and the deep roomy fuselage afforded ample space for ammunition, wireless, cameras, etc. From the table of performances it will be seen that both speed and climb were very good indeed for the power, and this is of particular interest in view of the comparatively large cross sectional area of the fuselage—14 sq. ft.—which does not appear to have adversely affected the speed of the machine. Originally the Type 530 was designed for a 300-H.P. Hispano-Suiza engine, but as this could not be obtained the experimental machines were fitted with 200-H.P. Sunbeam "Arabs" and 200-H.P. Hispano-Suizas.

The Three-Seater Bomber, Type 529A.

The reason for the apparent break in the series, by which the two-seater fighter, Type 530, comes before the 529A, is to be found in the fact that these two machines were going through the works at the same time, and the Type 530 was finished a short time before the other machine, October, 1917. The type 529A is a sister plane to the Rolls-Royce engined machine. From the table of performances it will be seen that both speed and climb of this machine were very good indeed, while at the same time she had a good range of action (556 miles at 10,000 ft.). She would therefore have made a good long-distance bomber, and should have been coming through in quantities in the spring and early summer of 1918. From the plan view of the machine it will be seen that the wings were arranged so as to be capable of being folded back, thus economizing storage room. The pilot sat just ahead of the leading edge of the planes, while a gunner was placed in the nose of the fuselage, and another gunner well aft, whence he had a good field for his machine gun. The engines fitted were Galloway B.H.P.'s of 220 H.P. each. The engines were very neatly covered in, and drove tractor screws, running in the same direction.

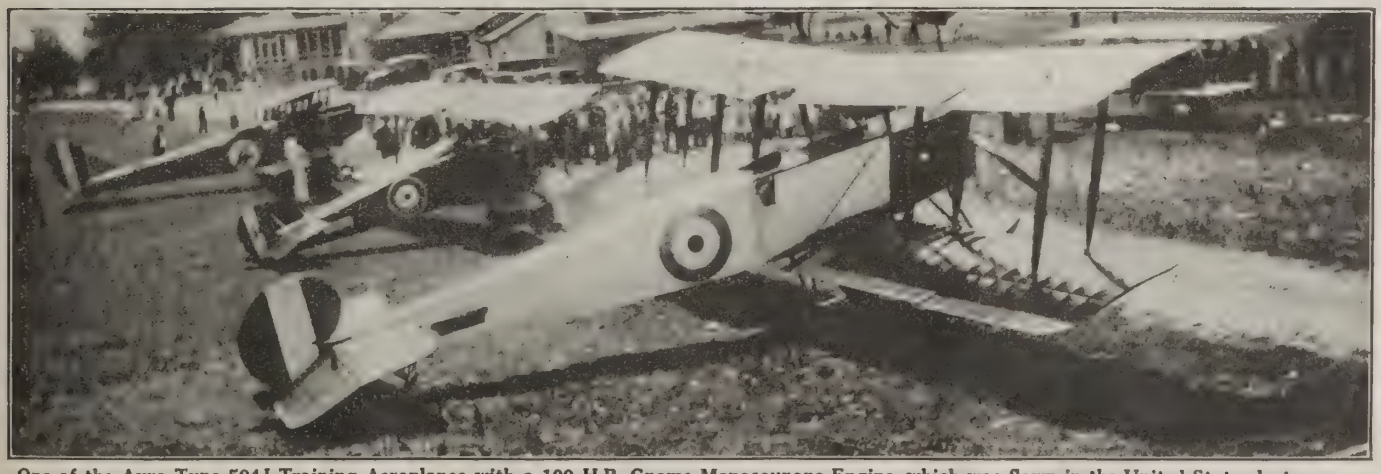
The Avro "Spider," Type 531

The following spring of April, 1918, saw an entirely different type of machine issue from the Avro works. This was a single-seater "Scout," in which the wing bracing was along quite unusual lines. From the illustrations it will be seen that, instead of the ordinary wing bracing wires or cables, the "Spider," as this machine was called, had Vee strutts arranged in the form of a Warren truss. In 1917 "Flight" published a series of articles by "Marco Polo," entitled "Wing Bracing and Head Resistance," in which this particular form of wing bracing was dealt with. In this article the author expressed the opinion that although the combination of Nieuport Vee struts and Warren truss did not appear to give the absolute minimum of resistance, it did have a low resistance, while at the same time having the structural advantage that the distance between supports was reduced, thus resulting in a lighter structure, and that therefore the arrangement might be found to be worth trying. This appears to be what the Avro designer has done. The "Spider" was said to be extremely monœuvrable and light on the controls, and the accompanying table of performance indicates that the machine had quite a good turn of speed—120 M.P.H. at ground level with a 130-M.P. Clerget engine is not bad—while the climb was also satisfactory. The pilot was so placed that his eyes were on a level with the top plane, in which a circular opening was cut out. This gave a good view both upwards and horizontally in all directions, while the small chord of the bottom plane gave a minimum of obstruction to downward visibility. The "Spider" might conceivably make a good sporting model, especially if fitted with a somewhat smaller engine, since the fuel bill for a motor of 130 H.P. would probably be more than the majority of owners would care to spend. However, as the machine is light there does not appear to be any reason why, in a slightly modified form, it should not be fitted with, say, an engine of 80-H.P. or thereabouts.

The Avro Type 530 two-seater fitted with a 200 H.P. Sunbeam Arab Engine



The Avro "Manchesters"

The success which was attained with the earlier model twin-engined machines, from the point of view of performance, encouraged the Avro firm to get out a design for a modern machine of this type, to be an improvement upon previous models chiefly as regards its engines, which were to be of the A.B.C. Dragonfly type, which was by then—we are now speaking of the earlier part of 1918—beginning to go into production, and which had an extraordinary power/weight ratio. With such engines available a very good performance was anticipated, and the drawings for the "Manchester" Mark I were got out. However, it was found that after all the engines could not be obtained, and so a silghtly modified form of machine was designed—the "Manchester" Mark II—which was fitted with two Siddeley "Puma" engines, instead of the two Dragonfly engines originally contemplated. The "Manchester" II was put through its tests in December, 1918, and gave, as indicated in the tables, very good results in the way of speed and climb. The two types of "Manchesters" are very similar, except, of course, as regards the engine housings. As in the previous Avro twins, the pilot occupies the middle seat, with one gunner in front and one in the rear. A feature which will scarcely escape the notice of readers is the unusual arrangement whereby the ailerons are balanced. Instead of the ordinary small forward projection at the outer end of the aileron, now so frequently seen on large machines, the "Manchesters" have a small auxiliary plane mounted on two short struts from the main aileron, and placed slightly ahead of it, so as to produce a balancing effect. The advantages expected from this arrangement are probably structural rather than aerodynamic, since by doing it in this fashion the twist of the aileron leading edge, caused by the usual balance placed at the extreme end of the aileron, is avoided. In some recent German machines a similar arrangement has been tried, but differing in that the small auxiliary plane is below the main plane instead of above it as in the Avros.

More recently the Dragonfly engines have been obtained, and the "Manchester" Mark I tried with them as originally intended, with good results. The "Manchester" II is being fitted with a cabin for passenger and mail carrying, and probably, therefore, more may be heard of this machine later on.

The Seaplane, Type 504L

Quite recently (February, 1919, in fact) a further development of the famous 504 type has taken place. This takes the form of a tractor seaplane with 130-H.P. Clerget engine, very similar to the standard Avro 504 in general arrangement, except, of course, the undercarriage, which is of the twin-float type. This machine is known as the 504L, and is not greatly different from the 1914 type of seaplane. The figures in the table of performances, relating to this machine, are the calculated figures, and we are informed that the actual tests have given even better results. Thus the calculated speed was, as shown in the table, 80 M. P. H. at sea level, whereas the machine actually does 90 M. P. H. The machine, which is fitted with dual controls, can be looped, spun, side-slipped, stalled, etc, just like the standard land machines. The 504L will also be arranged as a three-seater, with single controls and the pilot in front. The airscrew which was used for the test has Avro patent detachable blades. Finally, it might be mentioned that the machine will take all rotaries up to 150 H.P. and also the A.B.C. Wasp.

One of the Avro Type 504J Training Aeroplanes with a 100 H.P. Gnome Monosoupape Engine, which was flown in the United States last summer

NAVAL and MILITARY AERONAUTICS

Army Surgeons in Long Flight

Washington, D. C.—A recent successful flight by Army surgeons from Florida to Washington, a distance of 1,360 miles, was made in 18½ hours actual flying. This was the longest flight made by officers of the medical corps, although a medical officer had previously made a longer trip as a passenger.

The purpose of the trip was to stimulate interest among officers of the medical department in flying. Major S. M. Strong, post surgeon of Carlstrom and Dorr aviation fields, Florida, was in charge of the three airships which made the flight from Florida to Washington. Major Strong is working on an aerial ambulance and is hopeful of perfecting a machine of this type, for real war work, with a capacity of from 2 to 15 patients.

There were two men in each of the three ships piloted from Florida to Washington. Major Strong, with Lt. R. W. Brown, acting as adjutant of the group, were in the first aeroplane; Capt. John H. Timberman, flight surgeon and historian of the trip, and Lt. John Langley, navigating officer, in the second, and Lt. Fred Austin, in general charge of the ships and supplies, and Sergeant H. S. Rasch, mechanic, in the third.

The machines were of the Curtiss type with Hispano-Suiza motors. As flight surgeon, Capt. Timberman made a study of the physical and mental condition of the men making the flight, including expects to make the return trip to Florida their blood pressure and pulse. The party early next week.

Capt. Kindley, Who Downed 12 Planes, Returns on Transport Tiger

Captain F. E. Kindley, of Gravette, Ark., who has twelve enemy planes to his credit, arrived at New York on June 27 aboard the transport *Tiger*. He has the D. S. C. with oak leaf as a decoration from his own country, and the Distinguished Flying Cross from Great Britain, as well as the Croix de Guerre from France. The captain was with the 141st Aero Squadron, of which he had command on the transport. He left the United States on September 16, 1917, as a cadet flyer.

Air Service Instruction for High School Students

Washington, D. C.—The fact that forty high school graduates just completing their work at New York City high schools have enlisted in the Air Service in preference to seeking instruction at technical schools has called the attention of Air Service officers to an excellent field for obtaining recruits of the highest order.

Accordingly an energetic campaign is being prepared to present the opportunities for higher education and technical aeronautical instruction to high school graduates in all parts of the country. A number of aviation officers will be detailed for this work and Educational Boards will be requested to include such an officer as a speaker in the graduation program of public schools.

Bombardment Squadron Ordered to Border

Washington, D. C.—The 96th Aero Squadron, the first American bombardment squadron to see service on the Western front, has entrained for the Mexican border for observation duty on this side of the line. Capt. Cecil G. Sellers, D. S. C., formerly commander of the 96th is in command.

Lieut. Col. H. B. Hersey Discharged from Air Service

Washington, D. C.—Lieut. Col. H. B. Hersey, formerly commanding officer of the Army Balloon School at Fort Omaha, Nebraska, later of the Army Balloon School in France and finally in the Administrative Dept. of the Balloon Division at Washington, has, at his own request been honorably discharged from the service. Colonel Hersey will assume the office of District Forecaster, Weather Service, Milwaukee, Wisc.

Air Service Officers Recommended for Regular Army Commissions

Washington, D. C.—According to an official statement, Class III officers (those who have requested commissions in the regular army) desiring service in the Air Service total 2,297, and recommendations have been made on behalf of 2,297 officers.

Single Wing Insignia to Be Discarded

Washington, D. C.—The Advisory Board of the Air Service has recommended the use of the double wing insignia for all officers who participate in regular and frequent flights. Distinctive insignia for the following ratings are suggested: Aerial gunner, aeroplane observer; aerial bomber and balloon observer. The question of ratings and insignia for dirigible pilots is also being considered.

Distinguished Service Cross Awarded

The Commander-in-Chief, in the name of the President, has awarded the Distinguished Service Cross to the following officer for the act of extraordinary heroism set forth after his name:

The Vickers commercial type "Vimy" machine equipped with two Rolls-Royce 375 H.P. engines. Two pilots are carried in the cockpit placed high in the nose and the cabin has a seating capacity for 10 passengers in separate arm chairs. Fuel is carried for five hours; speed, 110 M.P.H.

FIRST LIEUTENANT WILLIAM P. ERWIN, First Aero Squadron, (Pilot). For the following act of extraordinary heroism in action near Sedan, France, November 5, 1918. Lieutenant Erwin is awarded an Oak Leaf Cluster to be worn with the Distinguished Service Cross awarded him October 1, 1918. Against the advice of experienced officers he undertook a reconnaissance flight in the face of atmospheric conditions that rendered flying most dangerous. In order that his observer might gain the necessary information, he was forced to fly at a perilously low altitude, and was subject to continuous anti-aircraft and rifle fire. When information gained on the flight had been dropped at division headquarters, he circled and returned over the enemy lines, although on the first reconnaissance mission his plane had been repeatedly hit by bullets. Penetrating far into enemy territory, he manoeuvered most skilfully, and with shells bursting near him, flew low while his observer poured deadly fire upon machine-gun nests that had been holding up the advance of our troops. When his machine was crippled by enemy fire, he displayed exceptional skill in effecting a landing upon rocky land within the enemy lines. With his observer, he beat off repeated enemy attacks and fought his way back to the American lines, with information of vital importance to our troops.

Home address: W. A. Erwin, (Father), 814 Fine Arts Bldg., Chicago, Ill.

Army Appropriation Provides $3,260,000 for Purchase of Wright-Martin Plant

Washington, D. C.—The $3,260,000 appropriation for the purchase of the Wright-Martin factory at Dayton and the 1,586 acres of property surrounding it survived all attacks in Congress and remains a part of the appropriation bill, which, from all indications, will be passed in the very near future.

Twelfth Aero Squadron to be Ordered to Border

Washington, D. C.—Orders have been requested of General Menoher for the transportation of the famous Twelfth Aero Squadron to El Paso, Texas, for duty on the Mexican border. The considerations which led to the ordering of this unit, which has just arrived from overseas for discharge, are that since the work required would be that of an observation squadron and that the better plan on account of the rapid demobilization in the United States and the need of thoroughly trained personnel was to send an arriving overseas squadron immediately and then relieve it as soon as competent personnel could be mustered from the training schools throughout the United States.

The Twelfth is in such splendid state of organization that they can operate immediately and the personnel is thoroughly experienced, having served throughout the Chateau-Thierry, Saint Mihiel and Argonne offensives.

Major Reed M. Chambers, an American ace, now commanding the Ninety-fourth Aero Squadron, which was the old squadron of Rickenbacker, made application to be assigned to the expedition in any capacity should it be necessary to utilize the services of a pursuit aviator. At present, however, it is believed that it will only be necessary to use observation planes, which can also be used for firing on the infantry on the ground.

South Americans Enlist in Air Service Here to Aid Home Industry

South Americans are flocking into the air service of the United States Army as a means of acquiring the necessary training for opening an extensive aero industry upon completion of their term of service. Since the beginning of the publicity campaign of the recruiting service a week ago six South Americans have been enlisted at one recruiting office in New York City alone.

Señor Bernardo Plata of Bogota, Colombia, who was one of the recent recruits said: "There are only three nations in South America that have aeroplane facilities—Brazil, Argentina and Chili—and there is now under consideration in Brazil an aero mail route serving Colombia and neighboring states. If this project is carried out it will be a tremendous stride in the progress of South American aviation, but there is no reason why Colombia should not be served by her own sons rather than be compelled to depend on outside interests for development."

First Balloon Company to Serve at Front Returns

Washington, D. C.—The Second Balloon Company, which the Patria brought back recently, was the first American air unit to see service on the western front, having entered the fighting zone in February, 1918. The company, commanded by Capt. I. I. Konig, of St. Louis, was attacked eighteen times and lost five balloons, but suffered no casualties.

Recent Naval Orders

Lieutenant (junior grade) Rodney B. Starr, to naval air station, San Diego, commandant Twelfth naval district.

Lieutenant (junior grade) Guy McKughlin, to naval air station, San Diego.

Lieutenant Earl R. Holmes, to naval station, Anacostia, D. C.

Lieutenant (junior grade) Francis R. McDonnell, to duty, naval air station, Chatham, Mass.

Lieutenant (junior grade) Harold J. Brown, to naval air station, Hampton Roads, Va.

Ensign Jack B. Bradig, to duty, naval air station, San Diego, Cal.

Ensign Carlyle S. Fliedner, to duty, naval air station, Far Rockaway, L. I.

Ensign Edward M. Tileston, to duty, naval air station, Cape May, N. J.

Ensign Byron J. Connell, to duty, naval air station, Rockaway, L. I.

Ensign Alford J. Williams, Jr., to duty, naval air station, Hampton Roads.

Special Orders, 143 to 149, Inclusive

Col. Milton F. Davis is relieved from his present duty in the office of the Director of Air Service, and from active duty to take effect June 30, 1919, and will then proceed to his home.

First Lieut. Philip De Riblet will proceed to Washington, D. C., and report to the Director of Air Service.

Second Lieut. Duncan L. MacIntyre is relieved from duty at U. S. A. General Hospital No. 10, Boston, Mass., and will proceed to Colonia, N. J., and report in person to U. S. A. General Hospital No. 3 for duty.

Second Lieut. Gavin D. Crandall will proceed to Hazelhurst Field, Mineola, Long Island, N. Y., and report in person to the commanding officer for assignment to duty with the 4th Aero Squadron.

Second Lieut. Bennett E. Meyers will proceed to Love Field, Dallas, Texas.

First Lieut. Christopher O. Anderson is relieved from his present duties and will proceed to Washington, D. C., and report to the Director of Purchase, Storage and Traffic for assignment to duty in the Office of the Director of Finance.

The following-named officers will proceed from Rockwell Field to Mather Field, Sacramento, Cal., for duty: First Lieut. Edward V. Wales, First Lieut. Robert Kauch, Second Lieuts. William Goldsborough, Emil C. Kiel, Augustus Goodrich, Eugene C. Batten, Robert O. Weede.

The appointment on May 2, 1919, of Second Lieut. Charles N. Fitts, for the period of the existing emergency by the commanding general, A. E. F., France, as announced in paragraph 28, S. O. No. 122, A. E. F., France, May 2, 1919, to the grade of first lieutenant, Air Service, with rank from May 2, 1919, is confirmed.

The following-named officers will proceed to Hazelhurst Field, Mineola, Long Island, N. Y., and report in person to the commanding officer for assignment to duty with the 4th Aero Squadron: Second Lieut. Earle H. Manzelman, Second Lieut. Charles Y. Banfill.

Paragraph 26, A. E. F., No. 142-O, W. D., June 18, 1919, directing First Lieut. Eugene H. Barksdale, to proceed from Hazelhurst Field, Mineola, Long Island, N. Y., to aviation general supply depot, San Antonio, Tex., is revoked.

Second Lieut. Howard K. Ramey will proceed

Commander A. C. Read, U. S. N., hero of the first trans-Atlantic flight, about to make a flight in a Breguet Bomber, with the famous French pilot, Lieutenant Roget, at Villacoublay, France

FOREIGN NEWS

Bristol Fighter First Plane to Cross Pyrenees Into Spain

London, England.—Major Payne and his observer, Major Coe, earned for themselves the distinction of being the first British aviators to enter Spain by air. Both officers were loud in their praises of the manner in which the Bristol machine had responded to the demands made upon it during the flight.

The journey was not wholly a pleasant one—the weather conditions militated against that—but the Bristol machine forged steadily along through fog and hail and crossed the Pyrenees from France to Spain at a height of about 15,000 feet. A landing was made in the province of Soria, near Madrid.

After spending a few days in Madrid the aeroplane returned to London, and the schedule of the time occupied in the return flight makes interesting reading. Madrid was left at 6.40 a. m. and a descent was made at Vittoria some two hours and twenty minutes later. At 10.30 the journey to Pau was started and that venue was reached at 10.40 p. m. Pau to Tours occupied from 1.55 to 5.20 p. m. and from Tours, which was left at 6.30, the Bristol made a non-stop flight to Hawkinge aerodrome, where the machine landed at 9.45 p. m. The total time in the air during the journey was thus about 11 hours. When one remembers that the last part of the journey was accomplished in the dark the performance amply justifies the admiration with which the aeroplane and its pilot were regarded in Madrid.

Grand Prix de l'Avenir for Aerial Tour Through France Totals 100,000 Francs

Under the title of the "Grand Prix de *l'Avenir*," a trial is being organized in France by the French journal, *L'Avenir*, with the object of demonstrating the practicability of aircraft for touring and transport purposes. It will be held under F.A.I. rules, with the patronage of the Aero Club of France, and be open to competitors of French or Allied nationality using machines of French or Allied construction.

The full distance will be about 3,000 kilometres, and will be flown in six stages. The first will be from Paris to Angers, *via* Rouen, Havre, Deauville and Dinard; the second from Angers to Bordeaux by Romorantin; the third from Bordeaux to Marseilles, the fourth from Marseilles to Lyon *via* Montpellier; and the fifth from Lyon to Metz *via* Strasburg; and the sixth from Metz to Paris *via* Lille. There will be certain controls on this course, details of which will be arranged later. The controls will be open between 7 a. m. and 8 p. m., but no machine will be allowed to start after 3 p. m. The start will be from Paris on August 26, and all machines must arrive in Paris by the closing time on September 1.

Entries must be made to the Aero Club of France before 6 p. m. on June 30, the fee being 1,000 francs, which is returnable on the machine completing the first stage in accordance with the regulations.

The prizes amount to 100,000 francs, and will be divided into two groups of 50,000 francs. The first section will be split up into prizes of 20,000, 15,000, 10,000 and 5,000 francs, which will be awarded according to the general classing, while the other section will be divided into five sets of prizes of 3,000, 2,000 and five of 1,000 francs, to be given on the classification for each of the first five stages.

The general classification will be by a system of marking. A non-stop run will count ten marks, while a machine which is a day late at a control will lose 3 marks. Each landing outside a control will cost one mark, and replacements will be penalized, changing a wheel, propeller, rudder, elevator, etc., costing one mark, a radiator two marks, a cylinder wing, etc., five marks.

Two or three climbing tests will be made before the start to determine the load to be carried. The competitor will declare the weight, and the machine will have to carry this to a height of 3,500 metres above the point of departure within one hour, and on descending, the machine must show the starting weight minus only the weight of the normal amount of fuel and lubricant consumed. When this weight has been decided upon, it will be painted on the *fuselage* or rudder of the machine.

The machine will be stamped and sealed before the start, and spare parts may be sealed also, but they will have to be carried on board.

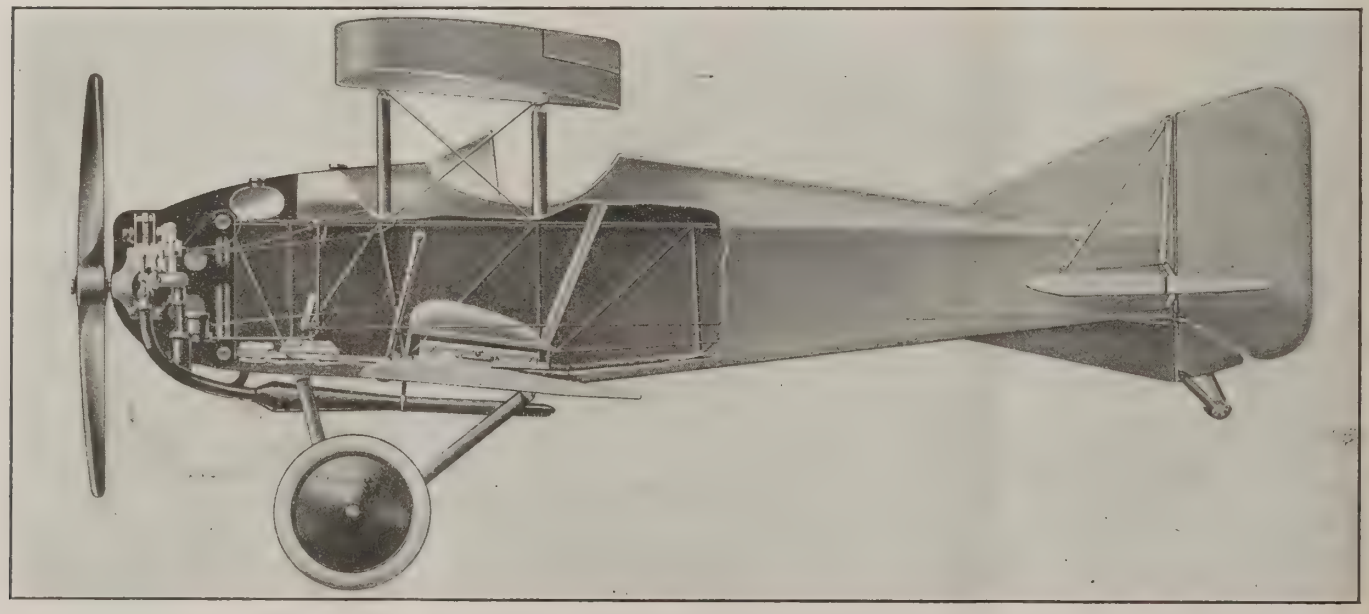
At least one passenger must be carried, passengers must be over 18 years of age, and weigh at least 65 kilogs.

Bristol Scout Fast Climber

During recent tests at Farnborough with the "Bristol" Scout, type F, some really remarkable results were achieved. The machine, which was fitted with a 315 h.p. Cosmos "Mercury" engine, climbed a height of 10,000 feet in 5 minutes 25 seconds, and at that height attained a speed of 143 m.p.h. A height of 20,000 feet was attained in 16 minutes 15 seconds. Ease of control is one of the outstanding features of this machine, and it may be landed at 49 m.p.h. A notable feature from a constructional point of view is that the ailerons are fitted to the top wings only, and the wing bracing is characterized by center section and interplane struts of "N" formation. The tail unit is entirely of steel and the structure of the whole machine is particularly strong. It is quite a small model with an overall length of 20 feet, a wing span of 29 feet 6 inches, a maximum height of 7 feet 10 inches and a wing area of 260 square feet.

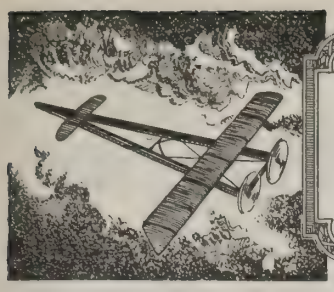
The Austin "Whippet" Aeroplane

For some time the designing staff and the experimental shops of the Austin Motor Co., of England, have been concentrated on the design and manufacture of a single-seater aeroplane which it is hoped will take the place of the motorcycle for demobolized and undemobolized pilots. The price of the machine has been fixed tentatively at about $2,000.



It has been the object of the designers to provide for reliability in the air, slow landing speed, ease of control, simplicity of rigging, small running cost and small housing accommodation. The "Whippet" has been designed with a factor of safety more than twice that adopted in pre-war machines of lower speed.

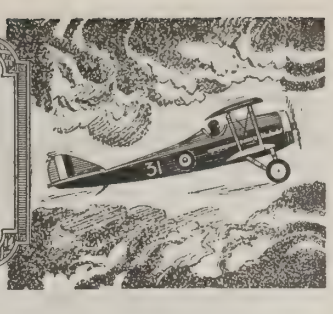
All fittings are made of a special high-tension steel. Wings have been designed with exceptionally small loading and the landing speed will be about thirty miles per hour, so that it could land on a small field or on a road clear of traffic.



High speed estimated at 95 m.p.h. Inherent stability has been aimed at with good manoeuvrability. As to rigging, the machine has been designed so as to require practically no attention after it has left the makers' hands. In order to obtain this result the fuselage has been constructed throughout of steel tubes and without bracing wires, the wing struts have been made of stream-line tubing and bracing wires have been eliminated and replaced by the tubular members. It is anticipated that a gallon of gasoline should more than cover a thirty-mile flight. In order to get over the trouble of housing, the wings of the machine are made to fold and allow the machine to be stored in a garage 18 ft. by 19 ft. by 8 ft. 6 in. high.

The "Whippet" is a single-seater biplane and should have users in business as well as in pleasure and sport. It has a tractor screw driven by a 45 h.p. twin-cylinder horizontally-opposed engine. Weight, empty, about 500 lbs.; fully loaded, 730 lbs. Its tank capacity is sufficient for a two hours' flight. It should climb to 5,000 ft. in 6 minutes and to 10,000 in 14 minutes.

For starting a small pump is provided for forcing mixture into the cylinders and the pilot starts his machine from inside with a starting magneto. Provision is made to carry luggage under the seat and cowling and wind-screen are arranged to give complete protection from the weather.



The Austin 45 H.P. "Whippet" biplane which has a speed range of 30-95 miles per hour

ELEMENTARY AERONAUTICS and MODEL NOTES

By John F. McMahon

Model of NC-4 at Hotel Imperial

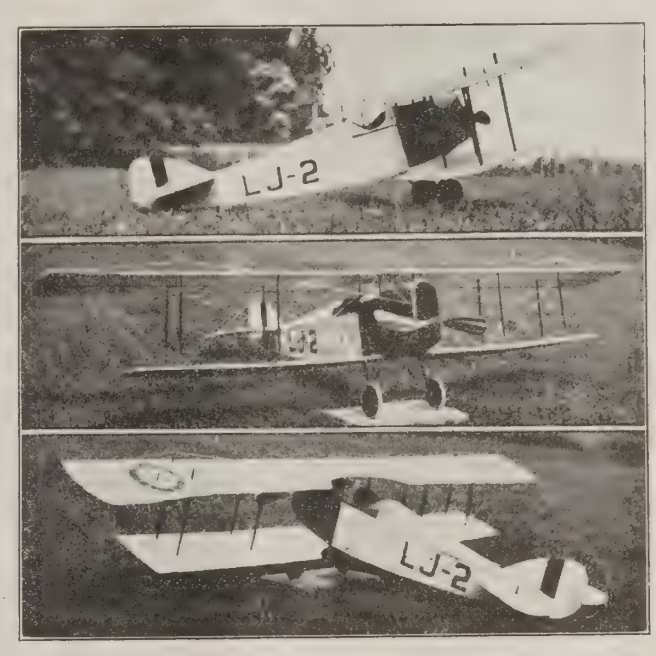
Mr. J. O. Stack, president of the Hotel Imperial, New York, is in possession of the first scale model of the Navy's NC-4 transatlantic flying boat. This miniature aeroplane is built at a scale of three-eighths of an inch to the foot, and all details, even to the engines, are faithfully reproduced in true scale, so that photographs of the model compare favorably with those of the real machine.

The upper wing has a span of 3 ft. 11 in. and the lower 2 ft. 11 in. Wing chord, 4½ in.; gap between wings, 5 in. to 4½ in. Length overall, 2 ft. 2 in. The hull is 1 ft. 5 in. long, 3¾ in. deep. Span of upper tail plane, 1 ft. 2 in.; lower tail plane, 10 in. Chord, 3⅜ in.; gap between tail planes, 3⅜ in.

Wings and tail planes are painted buff color. Hull, wing pontoons, struts and outriggers are painted with regulation battleship gray. Engine nacelles are painted with alumium to resemble the sheet aluminum covering. Engines are painted black and radiator faces are painted dark gray. Numerals are white and insignia of the Air Service are painted in customary red, white and blue, the red appearing on the outside circle.

The NC-4 model is now on exhibition in the main corridor of the Hotel Imperial, where it attracts a good deal of attention.

Mr. Stack, who is a member of the Aero Club of America, had scale models built of ten of the best known allied aeroplanes and the addition of the NC-4 makes the collection the most complete of its kind.



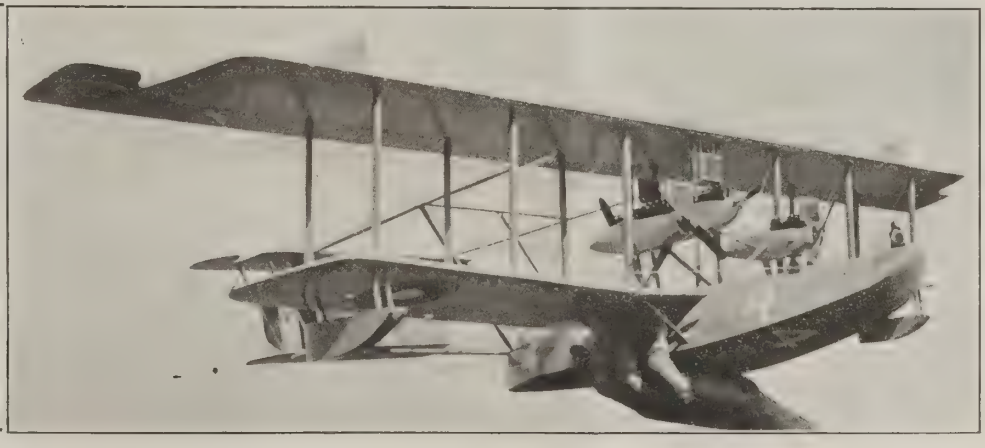
The models were first used at the hotel in a scheme of decoration for one of the banquet rooms, which was appropriately decorated with aeronautic insignia and symbols. During the war this room was converted into an officers' club and was much appreciated by the officers of the Allied armies and navies.

Model of the Holterman Biplane

The model shown in the upper right hand photograph is a perfect copy of the little biplane which was built by Eddie Holterman, ex-civilian instructor and tester for the government at San Antonio, Texas.

This model was made by J. Wm. Batchelder, 14 years old, of Woodstock, Vt., and is complete in every detail, as you can see. This model was built to fly and it is Master Batchelder's intention to power it with a short rubber band motor and a heavier propeller to bring the weight nearer to the nose so that the center of gravity will come at the proper place. As it is now the model is tail heavy and will not fly, but the changes mentioned will correct the balance of the machine sufficient to allow short flights to be made.

It is a mighty hard proposition to get a scale model to fly because of the weight of the tail works and the rubber motor running all the way to the rear, which brings the center of gravity at a point about midway between the trailing edge of the planes and the leading edge of the tail works. Many model flyers have given up model building on account of this, but if they only exercised a little patience and made their propellers heavier and shortened the rubber motor, and, if necessary, added a little lead weight to the nose of the machine so that the model would balance at a point about one-fifth the distance back of the leading edge of the main plane, the model would fly. This would not be correct for a full size machine as the center of gravity is located at about one-third back of the leading edge of the planes, because the



Model of the Holterman Biplane

weight is centered around this point, especially the pilot passenger and the motor, while in a model the weight is distributed the full distance of the fuselage.

Mr. Holterman's little biplane was shown on this page some time ago, and some readers will remember it was powered with a special motor made up of Ford motor parts. This machine had wings of equal spread, but he later found that an increase in surface would help the machine considerable so he decided to increase the top wing span and make it 36 feet. The bottom wing is 26 feet, which makes an overhang of 5 feet.

Master Batchelder has made the model according to the changes and to a scale of 1 inch to the foot. Mr. Holterman's machine was christened the "Lady Jane" so this one is the "Lady Jane, 2nd," as the lettering shows.

An accurate 4 foot scale model of the NC-4 flying boat, built from plans and description appearing in a recent issue of Aerial Age. It is provided with all the details visible in the real machine

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

"Airyplanes" and Women

"A woman is just like an Airyplane," said Pop Jiggs to Maggie, after viewing a flight. "Now what's on your mind?" exploded friend Wife.

"Now keep your Lateral Balance while I Air me views. An Airyplane can't go out at night without a Pilot, can it? No? And neither can a woman; at least not if she cares what the neighbors might say. It takes a durn good Pilot to Steer a High-power woman through Noo York at night. She always wants to Yaw off the Course (usually off the fish course and toward the Port). Fill her Tanks and she's off, losing her Longitudinal Stability, and maybe takes a Nose Dive ending in a Pancake. A good Pilot can prevent this by tugging at her Elevators and warping her Ailerons (or Balancing Flaps). As her Load per square foot increases, she will settle steadily; her Altimeter registers Descent, and her Exhaust decreases from that of a Liberty Twelve to that of a Mercedes Six. On the other hand, however, she may increase her Angle of Attack, causing the Pilot to Bank more heavily or lose Control of her. She Glides around; her Longerons sway; she Floats gracefully to Starboard then to Port; her Flight Path is the shape of a badly coiled Top Rope. A Step, a Stagger, a Strut, a Skid, a Side Slip, a Sweep Back.

"All good Flights must end, the Spirits run out, her Drag increases, she Drifts then Stalls, her Engines won't move her Propellers, she acts as if Doped. It's then the Pilot is most needed to Guide her safely back to Terry Firmy."

G. A. R.

Ace Revere

Listen, my children, and you shall hear
  Of the midnight flight of Ace Revere,
On the 15th of April in seventy-five;
  Hardly a man is now alive
Who remembers the famous flight that year.

He said to his friend: "If the British hop
  From yonder sea to the town to-night,
Send signals aloft from the belfry top
  Of the North Church aerodrome landing site;
Remember you must not fail to see,
  For I on the opposite shore will be,
Ready to hop off and spread the alarm
  Through every Middlesex village and farm,
For Middlesex fliers to fly up with arms."

He has left the village and mounted the steep,
  And beneath him tranquil and broad and deep
Is the Mystic meeting the ocean tides;
  Now over the steeples and over tree tops
He hops and hops and hops and hops
  As his NC smoothly skyward glides.

It was twelve by the village clock
  When he flew o'er little Medford town.
It was 12.02 (hear his motor knock)
  When he sighted little Lexington.
He saw the gilded weathercock
  Swim in the moonlight as he passed;
And the meeting house rooftops blank and bare,
  Gaze at him with a dizzy stare
As if they were quite flabbergast
  At the dips and vrilles they did look upon.

So through the skies flew Ace Revere,
  And down from the clouds came his cry of alarm
To every Middlesex village and farm—
  A cry of defiance and "Look who's here."
A voice in the darkness and signals galore—
  A message that shall echo forevermore;
For born on the night wind of the past
  Through all our history to the last,
In the hour and darkness and peril and need,
  The people will waken and listen to hear
(As they recently followed the flight of Read)
  The Liberty motor of Ace Revere.

—G. W. L. Flushing in the New York *Globe*.

soon to attempt the over-seas flight. Officially, New Jersey will be glad to offer any of her facilities in co-operation with the associations endeavoring to arrange for the event, and you have full permission to permit the invasion.

(*Signed*) *Walter E. Edge, Governor.*

Subsequently Mr. Alan R. Hawley, Major Thomas S. Baldwin, U. S. Army dirigible expert, and Mr. Henry Woodhouse visited Cape May Naval Air Station to ascertain whether it afforded the necessary facilities for receiving and mooring the dirigible and whether it was better than the Atlantic City Airport for the purpose. It was found that the grounds available at Cape May were not as large or as suitable as the Atlantic City Airport and that practically all the necessary equipment for handling the large dirigible would have to be provided, as the Cape May station was only equipped to handle small Naval dirigibles. General Charlton was notified to this effect in a letter dated May 23, which he acknowledged under date of May 27, advising that a party of British experts was coming to the United States to inspect available grounds. The letter follows:

From: British Air Attaché, Washington, D. C.
To: Secretary, Aero Club of America,
297 Madison Ave., New York, N. Y.
Re: British dirigible being handled at Cape May Naval Station
Dear Mr. Secretary:

I am in receipt of your letter of May 23 in which you advise me that, after due inspection, Cape May Naval Station, handling the airship R-34; that Atlantic City remains the most convenient spot for their receiving; and that you are proceeding with your general arrangements at the latter place accordingly.

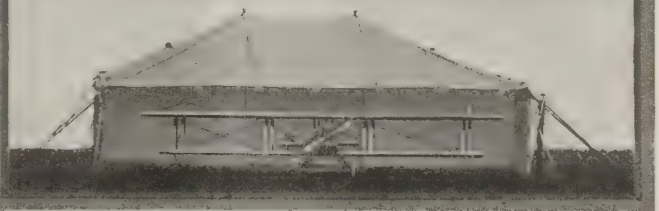
In reply I have to state that a party consisting of two officers and a small number of mechanics sailed from England per S.S. Adriatic on the 28th instant for the purpose of final inspection of reception arrangements. Upon the arrival of this party I will send them, or conduct them personally, to Atlantic City, there to place them in touch with the officials of the Aero Club who are concerned in the matter. I may add that upon the report of this Committee will depend whether or not Atlantic City will fulfill the requirements of the terminus for the voyage, and I have no doubt myself that everything will be satisfactory.

Thanking you for your regards and wishes, and hoping to be able to pay another visit ere long to Atlantic City, believe me,

(*Signed*) *L. Charlton, Brig.-Gen., Air Attaché.*

A meeting was then arranged, consisting of Messrs. Henry Woodhouse, Albert T. Bell, President, and Harry B. Cook, Secretary of the Atlantic City Aero Club, and W. W. Young, to mobilize the 700,00 cubic feet of hydrogen needed to inflate the dirigible. The rest of the equipment required had already been mobilized and everything was ready for the dirigible, excepting the hydrogen.

The Committee found that there were 46 hydrogen plants in the United States, having a capacity of from 8,000 to 60,000 cubic feet daily production capacity. The plants located within a radius of 75 miles of the Atlantic City Airport could supply immediately 3,000 hydrogen cylinders, each cylinder holding 198 cubic feet of hydrogen at a pressure of 1,800 pounds per square foot. They could supply the balance within a week.

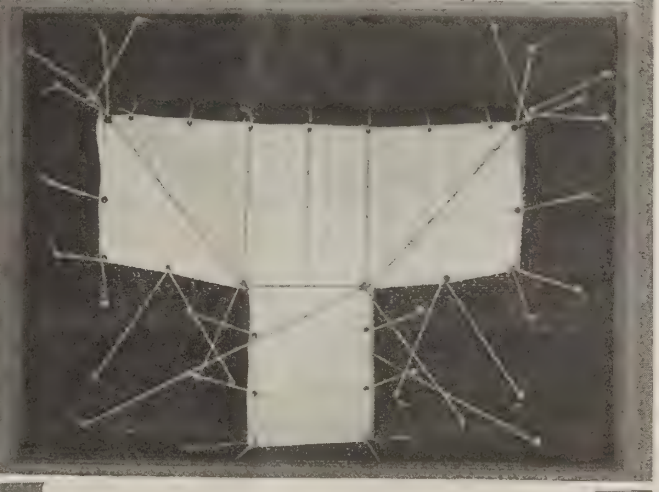


The Committee decided that it would be best to get these hydrogen plants and install them at the Atlantic City Airport as a permanent proposition, and a representative was appointed to go to Washington to get the sanction of the Army Air Service. Mr. G. W. Walton, a friend of a member of the Committee, who had been in the Supply Department of the Air Service, volunteered his services and went to Washington. There a meeting was called, which was attended by Army and Navy authorities and General Charlton, the British Air Attaché. At the meeting the representative of the Navy offered the co-operation of the Navy Department in handling the dirigible which was expected by General Charlton. It was decided that the Navy would supply the hydrogen, the gasoline, oil and mooring facilities at one of the Naval stations. Subsequently it was decided to use the Army Aviation Field at Mineola instead of a Naval station and to have the R-34 handled at the Army Aviation Field.

These arrangements were thoroughly satisfactory to the committee of the Aero Club of America and Aerial League of America, because it was realized that, besides the reasons already given, it would be better to have the event take place under the auspices of the Army and Navy for several reasons, and especially so as to have trained personnel under military discipline for the handling of the ship on the grounds, to avoid possible mishaps.

(Signed) Augustus Post, Secretary.

Portable Hangars for J.N.-4 Curtiss



Best of Material and Workmanship.
Fit like the glove to the hand.
Simple as A-B-C

AIRPLANE in hangar. Note room for camp beds at each side under top plane. Front wall closes on cable at top and lashes in center. Non-detachable pegs at bottom make it wind and rain proof.

BALANCE of power for wind resistance through double crossed guys removes strain from any one point and insures perfect safety in storms.

CAREFUL tests of canvas strength have proven the value of rope reinforcement. The heavy guys shown are built into the hangar

A.W.O.L. Prisoner Returns to Camp in Aeroplane

Stamford, Conn.—Charles Lowden of Stamford, who is in custody here for having overstayed a furlough from Mineola, is destined, according to police announcement, to be the first prisoner to travel as such through the air.

Weather permitting, he is to be transported from the city lock-up here to the guardhouse at Mineola to-morrow in an aeroplane. The young man enlisted recently and crossed Long Island Sound in the aerial ferry established to carry recruits from Stamford to Mineola.

Utz and Swander Now Vice-Presidents of Standard Parts Co.

Dan C. Swander and John G. Utz have been elected vice-presidents of the Standard Parts Co. Mr. Swander will continue as supervisor of sales and Mr. Utz as supervisor of engineering. Both men have been with the company since its organization. Mr. Utz was formerly director of engineering of the Perfection Spring Co. Mr. Swander previously was eastern sales manager of the Firestone Tire & Rubber Co.

Personal Pars

Julian S. Friede, recently released from the British Royal Flying Corps, has joined the engineering staff of the Haynes Automobile Co. Previous to his aviation service he was on the engineering staff of the Paige Detroit Motor Co.

Edward A. Hefferman, recently returned from the naval aviation service, will have charge of the office of the Ahlberg Bearing Co., recently opened in the City Bank Building, Kansas City, Mo.

Doehler Employees Form Benefit Associations

Brooklyn, N. Y.—The employees of the Doehler Die-Casting Co. have formed a mutual benefit association providing for compensation during illness and death benefits. A house organ known as *Doehler Topics* made its first appearance with the June issue.

A New Canvas Hangar on the Market

Canvas hangars built to house eight aeroplanes have been successfully designed and put on the market by the Henrix-Luebbert Mfg. Company of San Francisco, California. One of these hangars erected at Langley Field, Va., at one time withstood a 90 mile gale without being disturbed in the least. It is a remarkable fact that during this gale other hangars built of wood and corrugated iron were damaged to some extent.

A large hangar is now being erected on board a barge to house a flying boat and it is expected that there will be no trouble in keeping the hangar in good order. Hangars have also been designed for dirigibles and observation balloons and the company making them is prepared to undertake the design of a special hangar suitable for free balloons.

All of the Henrix-Luebbert hangars are erected without the use of manila or any other kind of rope, but steel cables are employed throughout, this patented principle being employed because of the difficulty in keeping a canvas hangar rigid when ropes are used which might stretch or shrink according to the weather.

During the War, the Henrix-Luebbert Company employed some 27 blind men and women to do some work in the construction and is now giving employment to returned service men including those who have met with accidents which do not handicap them in the careful performance of their work in this line.

Personal Pars

General George W. Goethals has announced that Mr. C. S. Jennison has been elected vice-president and a director of George W. Goethals & Company, Inc., consulting engineers, New York City.

Electrical Show to Be Resumed

The Electrical Exposition and Motor Show will open at the Grand Central Palace, New York City, on September 24th. Forty per cent of the space has been allotted to exhibitors. This will be the first show since 1917, the 1918 exposition having been omitted because of our entry in the war.

Automobile Tires Advertised and Delivered by Aeroplane

Houston, Texas.—The Aerial Tire and Rubber Co. of this city, distributors of automobile tires, are using an aeroplane for the sale, advertising, and in some cases, the delivery of motor car tires.

Personal Pars

Mr. J. L. Justice, who for the past three years has been associated with the Maxwell Motor Company of Detroit as zone supervisor, has left the Maxwell Company and taken a position as general sales manager of the National Wire Wheel Works, Inc. Mr. Justice will have his offices in the Book Building at Detroit, Michigan, in order to keep in constant touch with all the car manufacturers.

to Cooperstown, N. Y., and report to military hospital for treatment.

Second Lieut. William S. Heltzen is transferred with the necessary attendants to Walter Reed General Hospital, Takoma Park, D. C., for treatment.

Capt. Boyd F. Briggs will proceed to Hazelhurst Field, Long Island, N. Y., for duty.

First Lieut. Hugh A. Bivins will proceed to Americus, Ga., and report to aviation general supply depot for duty.

Second Lieut. John V. Hart will proceed to Hazelhurst Field, Mineola, Long Island, N. Y., and report in person to the commanding officer for assignment to duty with the 4th Aero Squadron.

Capt. Charles W. Babcock will proceed to Fairfield, Ohio, and report in person to the commanding officer, Wilbur Wright Air Service depot, for duty.

First Lieut. Henry V. Bell, unassigned, is transferred with the necessary attendants to U. S. A. General Hospital No. 43, Hampton, Va., for further treatment.

First Lieut. Bruce N. Martin, F. A. (attached to Air Service), will proceed to Hazelhurst Field, Mineola, Long Island, N. Y., for duty.

Second Lieut. Franklin A. Plummer will proceed to Camp Pike, Ark.

Capt. Samuel Katzman will proceed without delay to New York City and report to the United States Army recruiting officer, 461 Eighth Avenue, for duty in connection with the recruiting service.

The following-named second lieutenants will proceed to Belleville, Ill., and report to Scott Field for duty: Talcott P. Smith, Frank M. Paul.

Second Lieut. George H. McKay will proceed to Mineola, Long Island, N. Y., and report to the commanding officer Hazelhurst Field for assignment to duty with the 3d Aero Squadron.

First Lieut. Donald C. Bennett is announced as on duty requiring him to participate regularly and frequently in aerial flights from May 30, 1918, to July 31, 1918.

First Lieuts. Charles H. Thalman and Joseph B. Jiskra will proceed to San Antonio, Tex., and report in person to the commanding officer aviation general supply depot for duty.

First Lieut. Kenneth M. Foote will proceed to Dallas, Tex., and report to aviation repair depot for duty.

The rating of Col. Henry H. Arnold, junior military aviator, as military aviator, to date from May 20th, 1919, is announced.

The rating of Lieut. Col. Barton K. Yount, junior military aviator, to date from June 3, 1919, is announced.

Capt. Joseph M. Dawson will proceed to Middletown, Pa., and report to aviation general supply depot at that place for duty.

The rating of Maj. Dana H. Crissy, as junior military aviator, to date from May 20, 1919, is announced.

The appointment on May 8, 1919, of First Lieut. Eugene L. Sullivan, for the period of the existing emergency, by the commanding general, France, as announced in par. 6, No. 128-A, A. E. F., France, May 8, 1919, to the grade of captain, Air Service, with rank from May 8th, 1919, is confirmed.

The following-named officers will proceed from office district manager Air Service Finance, Buffalo, N. Y., to Detroit, Mich., and report in person to the commanding officer Aviation General Supply Depot for the purpose of discharge: Second Lieut. Charles S. Danielson, Second Lieut. Claude F. Griffis, Second Lieut. Paul W. Jenkins.

The following-named officers will proceed to Mather Field, Sacramento, Cal., and report in person to the commanding officer for duty: First Lieut. John P. Van Zandt, Second Lieut. Daniel L. Dargue, Second Lieut. Carlyle H. Ridenour.

Second Lieut. William R. Sweeley will proceed to Rockwell Field, San Diego, Cal., and report in person to the commanding officer for assignment to duty with the 2d Aero Squadron.

Second Lieut. John W. Powell will proceed to Montgomery, Ala., and report to aviation repair depot for duty.

First Lieut. Allan S. Willis will proceed to Fort Bliss, Tex., and report in person to the commanding officer of that post, and by letter to the department Air Service Office for duty.

Second Lieut. Morris L. Tucker will proceed to Scott Field, Belleville, Ill., for duty.

Capt. Cecil G. Sellers will proceed to Columbus, N. M., and report upon arrival, by letter, to the department Air Service officer, Southern Department, for duty.

Second Lieut. Henry H. Sprague will proceed to Hazelhurst Field, Mineola, Long Island, N. Y., and report in person to the commanding officer for assignment to duty with the 4th Aero Squadron.

Second Lieut. Charles G. Brenneman will proceed to Middletown, Pa., and will report to aviation general supply depot for duty.

Second Lieut. Marion L. Elliott will proceed to Hazelhurst Field, Mineola, Long Island, N. Y., and report in person to the commanding officer for assignment to duty with the 4th Aero Squadron.

Second Lieut. Clifford Elleman will proceed to aviation general supply depot, Richmond, Va., for duty.

Second Lieut. Percy O. Brewer, Air Service, will proceed to Camp Normoyle, Tex., and report to the commanding officer motor transport general depot for instruction in Motor Transport Corps duty. Upon the completion of this duty Lieut. Brewer will report to the commanding general Southern Department, Fort Sam Houston, Tex., for assignment to duty.

First Lieut. James L. Rochford will proceed to San Antonio, Tex., and report to aviation general supply depot for duty.

Second Lieut. Hiram W. Sheridan will proceed to Mineola, Long Island, N. Y., and will report in person to the commanding officer Hazelhurst Field, for duty with the 3d Aero Squadron.

By direction of the President, Lieut. Col. D. M. Cheston, jr., is honorably discharged as lieutenant colonel, United States Army, only, to take effect this date.

By direction of the President, Lieut. Col. Milton F. Davis (lieutenant colonel, U. S. A., retired) is honorably discharged as colonel, Air Service only, to take effect June 30, 1919.

Second Lieut. Floyd B. Meisenheimer will proceed to Belleville, Ill., and will report to Scott Field for duty.

First Lieut. Robert S. Houston is announced as on duty requiring him to participate regularly and frequently in aerial flights from January, 11, 1918.

THOSE practical dreamers who years ago visioned Aerial Mail and Express know now that their hopes are to be fulfilled.

For the plane—heavier than air—successful in war, is today carrying mail, merchandise and passengers.

Older in use, better known perhaps, the balloons—lighter than air—are bidding strong for like favor as carriers.

In Akron, Ohio, Goodyear balloon men have dreamed and worked, they have built and studied, they have learned balloon craft.

They are ready now to consult with, to help those of you who also believe in the nearness of Aerial carrying.

In designing balloons of any size and type, in building them—Goodyear balloon men are competent and capable.

VOL. IX NEW YORK, JULY 21, 1919 NO. 19

AMERICA TO ENGLAND IN SEVENTY-FIVE HOURS

CALCULATING by New York time right through, the R-34 started eastward over the Atlantic Ocean at midnight of Wednesday; sailed across the Irish coast in the mid-evening of our Saturday; landed at Pulham, a hundred miles northeast of London, well before the dawn of our Sunday.

To realize the marvel of this performance the exact figures of time elapsed are not needed. Hours and minutes make a statistical record. The R-34 has, in large terms, prepared the way for such a revolution in methods and means of travel as will be quite sure to change completely the relations of land to land, people to people, the world over. So the fourth crossing of the ocean by aircraft becomes the most notable in the series. It marks a close approach to the realization of an old, old dream of man; it goes down as a memorable triumph of mind, heart, courage and imagination.

To comment thus glowingly on the feat of the R-34 and its crew is to shade not at all the earlier transatlantic voyages on the air trail. Pioneer honors remain yet with the American NC-4 and its conductors. For audacity and speed the palm may long be held by the British flyers Alcock and Brown. The note of advance in the case of the great dirigible which has just completed its round trip is sounded over the detail of carrying capacity. For how long or how short a moment we cannot tell, the R-34 brings nearest to a practical basis the matter of establishing a literal airline traffic between continents.

Commenting on his eastward trip, Major G. H. Scott, commander of the R-34, said:

"We estimated we would make the return trip from America in from seventy to eighty hours. We made it in seventy-five. When we left Mineola we had a strong wind behind us, and we covered the first 800 miles in about eight hours.

"When we circled over New York we could plainly see the crowds in Broadway waving to us as we passed, but we could not hear them because of the noise of the engines.

"South of Newfoundland we encountered head winds and our progress from then on was slower. We traveled at an average height of from 3,000 to 5,000 feet and found much low clouds and fog. Once we saw nothing but fog for twenty-four hours.

"We struck Ireland at Clifden and made good progress from there, although our steering engine broke down Saturday morning. We started with 4,900 gallons of gasoline and had 1,000 left.

"We are naturally pleased with the trip, all of us. I expect important changes in the size and speed of future airships, big ships that will travel seventy to eighty miles an hour and powerful enough to crawl through anything."

Colonel W. N. Hensley, Jr., the United States Army observer on board, said:

"This has been a great trip. We were lost one whole day because the fog was so thick we could not get a shot at the sun, moon, stars or horizon. We passed over the Isle of Man about three o'clock this morning and then, mounting above the clouds, witnessed a most beautiful sight. Above was the bright moon; below, soft, fleecy clouds, touched with all the colors of the rainbow, and, far down below, the deep blue of the sea.

"We soon passed over Liverpool and then other cities and towns and here we are. We suffered no hardships and no inconveniences except that we had no hot water for shaving. Our eggs were cooked in the exhaust of the engines, and we had plenty of other good food and coffee, tea and cocoa to drink. No one suffered from airsickness, and while the sea below was tossed by a forty mile gale, we were moving along in comfort on an even keel.

"Regular airship service between Europe and America is bound to come, and soon."

The aeronautic experts assembled at the Atlantic City Airport were enthusiastic over the successful demonstration of the dirigible in its return trip. Mr. Henry Woodhouse, Chairman of the Dirigible Committee of the Aero Club of America and Vice-President, Aerial League of America, who had a prominent part in arranging to bring the R-34 to the United States and inspected the airship while it was at the Roosevelt Field, said:

"The successful return trip of the British dirigible R-34 completes this epoch making demonstration of the fact that airships are ready to operate as fast carriers of mail, express and passengers.

"Especially significant is the fact that the total time elapsed since it left East Fortune, Scotland, and including the stop of the R-34 at the Roosevelt Field, Mineola, only amounts to the time required for a ship of the sea to cross the Atlantic one way.

"For this reason this cruise, like the transatlantic flights of the NC-4 and Captain Alcock and Lieutenant Brown in the Vickers 'Vimy' are in every way as great achievements as the sailing vessel 'Santa Maria' in 1492 and the crossing of the first steamship, the 'Savannah,' in 1819.

"They are the first aircraft to cross the Atlantic in different ways and have opened the way for other aircraft to follow.

"The aircraft used for crossing the Atlantic have all been war craft with only minor changes. In these first trips the airmen have had to face difficulties due to lack of meteorologic data. With improved aircraft and the data accumulated in these first transatlantic flights, the crossing of the Atlantic will not only be easier, but even the stupendous records already made will be greatly improved, and permanent aerial lines for the transportation of mail and passengers will follow."

FIFTEEN GREAT AERIAL CONTESTS WITH CLOSE TO $1,000,000 IN PRIZES

FIFTEEN great aerial contests to come are announced by Mr. Henry Woodhouse, vice-president of the Aerial League of America.

The marvellous accomplishments of aviators during the past two months are to be followed by still greater achievements, Mr. Woodhouse states. The record of Captain Alcock and Lieutenant Brown in flying across the Atlantic in 16 hours, and the record of the French Lieutenant Casale, who flew up to over 33,000 feet, may not be capable of much improvement in the near future, but there are other great things to be done and proper incentive is being given to aviators to do big things.

Among the important events being organized which are to be held under the rules of the International Aeronautic Federation are:

(1) The Aerial League of America's Pioneer Aeroplane Tours, which are to start in the United States, then extend to Canada, Central and South America and other countries.

(2) The Aviation Competition being organized by the Aero Club of France, for which the President of the Club, Henry Deutsch de la Meurthe, has given $400,000.00.

(3) The $25,000 prizes offered by Raymond Ortig for the first flight from New York to Paris.

(4) The $50,000 prize offered by Thomas H. Ince for the first trans-Pacific flight.

(5) The $60,000 Echo de Paris prizes for a 2,500 miles circuit race.

(6) The 100,000 francs prizes offered by the French paper L'Avenir for cross country contests.

(7) The $50,000 prize to the first Australian pilot who flies from Great Britain to Australia.

(8) The $32,400 prize for the Portuguese or Brazilian aviator who flies from Portugal to Brazil.

(9) The International Marine Flying Trophy Race, for best speed over a distance of 200 miles, to be held in England in September, for which a prize of $5,000 is offered to the winner.

(10) The $5,000 prize offered by John McK. Bowman, for a race from Toronto to New York.

(11) The Intercollegiate Aeroplane Contests to be held at Atlantic City this summer for prizes offered by the Aero Club of America under the terms of the will of Mr. Samuel Valentine.

(12) The contests for National and International Aerial Shooting Championships.

(13) Seventeen entries and $10,000 in cash prizes and trophies are already assured for the aeroplane flights from Toronto to New York which are to feature the Canadian National Exposition to be opened by the Prince of Wales on August 25, it was announced tonight.

So far all entries for the Toronto-New York race are from the United States, but twelve Canadian entries are expected before the exposition opens. Captured German Fokker planes, now in the possession of the Dominion Government, will be admitted to the contests, it has been decided, provided their pilots hail from allied countries. There are twenty-two of these craft here now.

(14) The London Daily Express offers a prize of £10,000, open to the whole world with the exception of the late enemy countries, for an air flight establishing communication on a commercial basis with India and South Africa. All competing machines must carry a useful cargo of at least one ton on both outward and homeward flights.

Factors to be considered in the award will be the average reliability and airworthiness of the machines.

(15) Gabriele d'Annunzio, poet and aviator, has arranged to attempt a flight from Rome to Tokio and return. The trip will last altogether a month, and the aviator purposes to cover about 20,000 miles.

The route will lay through Asia Minor, India, Tonkin and China to Japan. D'Annunzio has arranged for stations along the route where he can replenish his supplies.

These contests, held under the rules and regulations of the International Aeronautic Federation, are open to all pilots holding a Federation pilot certificate, which is issued in the United States by the Aero Club of America, 297 Madison Avenue, New York City.

HAVE ANY MERITORIOUS CASES BEEN OVERLOOKED?

THE Aerial League of America has awarded Diplomas of Merit to Commander A. C. Read, the hero of the trans-Atlantic flight; Flight Lieutenant Stone and the other members of the crew of the NC-4, and Commander John H. Towers, Commander P. N. L. Bellinger, Commander H. C. Richardson, and the other members of the crews of the NC-1 and NC-3, and Commander R. E. Byrd, who invented the Byrd sextant.

Major-General Mason M. Patrick, who was chief of the U. S. Air Service overseas during the war, now the U. S. Army representative on the Aeronautical Commission of the Peace Conference; Rear-Admiral D. S. Knapp, U. S. Navy representative on the Aeronautical Commission of the Peace Conference; Brig-Gen. Theodore C. Lyster and Lt.-Col. I. H. Jones, who were foremost in organizing the Air Medical Service; Col. Halsey Dunwoods, executive officer of the U. S. Air Service overseas; Col. E. Lester Jones, Col. Charles Elliott Warren, Col. B. J. Arnold, Col. Thurman W. Bane, Col. C. G. Edgar, for exceptional services rendered to the United States during the war; Col. C. C. Culver, who developed the radio telephone; Lt.-Col. A. R. Chrustie, Lt.-Col. W. G. Kilmer, for exceptional efficiency while in charge of the U. S. Army Aviation centers in France; Col. Charles De F. Chandler and Col. Frank P. Lahm, for exceptional efficiency while in charge of the U. S. Army Balloon Service in France; Maj. J. C. McCoy, Maj. Thomas S. Baldwin and A. Lee Stevens, for exceptional efficiency in organizing the U. S. Army Balloon Service; Capt. Charles J. Glidden, for exceptional services rendered in recruiting for the U. S. Army Air Service; Maj. John M. Satterfield, for exceptional efficiency in connection with the administration of the Air Service in France during the war.

Every one of these men well deserved the honor conferred on them by the League. It would take pages to relate the extent of their achievements.

The League is considering the award of the Diploma of Honor to other officers in the Army, Navy and Marine Corps Air Service and to others who have rendered valuable services to the cause of civilization and humanity. The secretary of the League states that it is the League's desire not to overlook deserving men who should receive the diploma, which has also been awarded to all the aces, and to the parents of all those who lost their lives or were injured while in the service during the war. Readers of AERIAL AGE are requested to advise the League of any deserving case that may have been overlooked. Address the secretary, Aerial League of America, 280 Madison Avenue, New York City.

By these awards the League is rendering another service of national importance. The least the country can do to those who served faithfully and made sacrifices to help to bring the war to a successful end is to show its appreciation.

The News of the Week

New Army Airship in 407-Mile Test

Starting from Akron, Ohio, at 10 o'clock July 11, the new army dirigible A-4, flying against strong head winds, reached Bolling Field, Washington, at 9:45 a.m., July 12. After a stop of an hour and a half the airship rose again and started for Langley Field, Hampton, Va., where she arrived late July 12.

Reports to aviation headquarters said the dirigible covered the total distance of 407 miles in eighteen hours, flying time, at an average speed of a little more than twenty-one miles an hour. Heavy fog was encountered throughout the first lap of the journey, necessitating flying at a height of 4,000 feet. Lieutenant G. W. McEntire was in command, and had two assistants aboard.

The A-4 is 162 feet long and 33 feet in diameter. Its cubic contents are 95,000 feet. It has a total lifting capacity of 6,460 pounds.

Throngs See NC-4 in Park

Crowds of people have visited the NC-4, first transatlantic-air-cruiser, which is on view in the Sheep Meadow, Central Park. The flying boat is in a roped inclosure and a guard is established to prevent the spectators from surging in upon it.

The exhibition of the plane in New York probable will end August 1. Then the machine will be taken apart for shipment to Washington, where it will be reassembled and mounted at the Smithsonian Institution.

Raymond Ware Marries

While Miss Catherine Munroe Schurman, eldest daughter of President Schurman of Cornell University, was being married in Sage Chapel on July 12 to Raymond Ware, of the Thomas-Morse Aircraft Corporation, a squadron of aeroplanes soared back and forth over the church. Dr. Henry Van Dyke of Princeton officiated at the wedding.

Charters Seaplane to Catch Steamer at Sea

Chartering a seaplane at $1 a minute for a flight to catch the steamer Kaisha Maru, which he missed when the vessel sailed from Seattle for Oriental ports, J. J. Mayer, Seattle Red Cross worker, booked for Vladivostok, succeeded in catching up with the ship near Port Townsend, Wash., after a thirty-five minute flight.

Aviators 20,000 Feet in Air Saw Two Sunsets in a Day

Seeing two sunsets in one day was the experience of two army aviators at Arcadia, Fla., in an altitude flight on July 10.

Leaving Carlstrom Field after dark, in an experimental flight for altitude, Lieutenant Charles C. Chauncey and Sergeant Thomas Cook soared in a Le Pere aeroplane to a height of 20,000 feet. The weather at the height was clear, the thermometer in the rear cockpit registered five degrees below the freezing point, and the sun was sinking below the western horizon.

First U. S. Airplane Flies Into Canada

Armed with the first permit ever granted by the Canadian military authorities for an aeroplane flight across the international boundary, two American aviators arrived July 12 on a "courtesy visit" to the Aerial League of the British Empire, Montreal Branch.

The visitors, Lieut. O. S. Parmer and Ensign G. D. Garmon, flew from the Junior Camp at Plattsburg, N. Y., covering forty-five miles through a heavy rainstorm in fifty minutes.

Buffalo to New York in Five Hours

Roland Rohlfs, experimental pilot for the Curtiss Aeroplane and Motor Corporation, flew from Buffalo to New York on July 10 in a Curtiss Oriole three-passenger aeroplane in five hours and two minutes, thus making the trip in almost half the time of the Empire State Express.

From Buffalo to Albany Mr. Rohlfs averaged 100 miles an hour. Below Albany, where cross winds were encountered, the speed was reduced to sixty miles an hour.

The flight was made for the purpose of carrying to New York in time for the dinner given by Glenn H. Curtiss to the commanders of the transatlantic seaplanes at the Commodore Hotel, Thursday night, 200 copies of a history of the flight which were printed too late to catch the train from Buffalo. The books reached Garden City at half-past six o'clock in the evening and were delivered soon after the diners sat down.

Mr. Rohlfs will attempt in the next few days to beat the world's altitude record of 33,136 feet.

Aerial Board in Paris Announces Air Rules

Principles to govern aerial navigation, already accepted by most of the Allied Nations, have been announced by the Aeronautical Commission of the Peace Conference, which recently ended its work. These principles are contained in an international convention which provides for the creation of an international commission. The principles laid down concern the nationality of airships, certificates of navigability, rules for flying, lists of forbidden routes, steps to be taken by all signatory nations to develop aerial navigation, various provisions governing the licensing of aviators, equipment of aeroplanes with signals, distribution of weather reports and customs regulations.

Madam Petrova in Aerial Contest

Having become so greatly enthused over aeronautics since her first visit to the Atlantic City Airport a month ago, Madam Olga Petrova, the noted Russian star of the screen and the speaking stage, paid a second visit to the Atlantic City Airport on July 10.

Accompanying Madam Petrova was Mr. Jules Aaronson, managing director of the Keith theater interests in Atlantic City, where Madam Petrova in playing a return engagement.

Madam Petrova has become so enthusiastic over aviation from a sporting and commercial standpoint that she challenged Mr. Aaronson to a race of twenty-five miles for a wager of $1,000, and great interest centered in the contest which was witnessed by a large assemblage of spectators, including over a thousand prominent Elks from all parts of the country who are in Atlantic City attending the Grand Annual Elks' Convention.

The race started at eleven o'clock from the Atlantic City Airport and was over a course of twenty-five miles along the beachfront, where it was witnessed by thousands of cheering promenaders on the

Madame Olga Petrova, noted Russian star of the screen and speaking stage; Mr. Jules Aaronson, Managing Director of Keith's Theatre interests in Atlantic City; Captain Marucus, Medical Service, U. S. A.; Mr. Mark Ovenden, of the Executive Staff, Atlantic City Airport, and prominent Elks attending Annual Elks' Convention in Atlantic City, in front of Aerial League of America Clubhouse on Atlantic City Airport, just after Madame Petrova's aerial race of 25 miles with Mr. Aaronson, for a wager of $1,000

Boardwalk, where the interest in the outcome ran high. Mr. Aaronson covered the distance in 18 minutes and 30 seconds, with Madam Petrova a close second, finishing in 18 minutes and 42 seconds.

The interest shown by prominent Elks who witnessed the race and who attended the special aerial program, held on Elks' Day, July 9, augers well for the rapid advancement of aeronautics, as the lodgemen are from all parts of the United States and include in their number Governors of States and high Government officials, many of whom complimented the officials of the Airport on its up-to-date facilities for the receiving and housing of aircraft and predicted that the very near future would see the aeroplane in the role of an absolute necessity in the commercial world.

Aerial League to Collect Meteorological Data

Having been advised by the officers of the British dirigible and Army and Navy officers the frequency of transatlantic aerial cruises depends on the building of suitable hangars and making available meteorologic data regarding prevailing winds and other aerologic data, the Aerial League of America has taken steps to collect this data and establish a center where air navigators can gather all the information available on the subject.

The Committee of the Aerial League who visited the Atlantic City Airport decided that the Airport is the most favorable place to establish such a station, and arrangements are being made to use one of the buildings at the Airport for this purpose.

The Aerial League of America will cooperate with the U. S. Weather Bureau, the Coast and Geodetic Survey, the Army, the Navy, the Post Office, the Aero Club of America, and other Government and scientific and aeronautic organizations interested in the development of science of aeronautics.

The Aerial League has already gathered at the Airport an extensive collection of transatlantic flights' data, including photographs and reports and charts of all the transatlantic flights made or planned. This includes about fifty photos showing the NC seaplanes and the Vickers-Vimy taken in different stages of construction and at different periods during the transatlantic flights.

The committee which will supervise the work of collecting this data includes the following prominent aeronautic authorities: Rear Admiral Robert E. Peary, Major Thomas S. Baldwin, Henry Woodhouse, vice president, Aerial League of America; Colonel E. Lester Jones, Director Coast and Geodetic Survey; Colonel Charles Elliott Warren, Captain Robert A. Bartlett, John Hays Hammond, Jr., Albert T. Bell, Brigadier General Theodore C. Lyster, Colonel Isaac H. Jones, Lieutenant Lawrence B. Sperry, U.S.N., Captain Granville A. Pollock, Rear Admiral Colby M. Chester, and G. Douglas Wardrop.

Cleveland Aviation Club Entertains N-C Crew

The Cleveland Aviation Club entertained the crew of the N-C-4 at the Yacht Club, Cleveland, on July 14. Ensign Rodd, who is a native of Cleveland, was presented with a loving cup. The meeting was a most enthusiastic one.

Aero Club of Iowa Formed

Capt. James Normal Hall, of Colfax, Iowa, has been named honorary president of Aero Club of Iowa, recently organized at Des Moines, at a luncheon attended by a score or more of Iowa aviators. A campaign has been started to secure the names of the many flyers in the state who have received their pilot's training both in this country and on the other side.

Officers of the new organization were chosen as follows: Clarence M. Young, president; Dale Griswold, vice-president; Harvey Ray, secretary, and Howard C. Eales, treasurer. An advisory board of prominent and influential men from various parts of the state will be named. Several state officers, including Governor W. L. Harding, have expressed their desire to become affiliated with the organization.

The Iowa club promises to be a live organization and already a number of movements for the promotion of commercial aviation have been launched. One of the first steps to be taken up will be the establishment of municipal landing fields. Several commercial aviation enterprises have been started in the state, and a number of other projects are under way.

Elks Visit Atlantic City Airport

Close to ten thousand Elks from all parts of the United States and members of their families visited the Atlantic City Airport, the first airport in the world, on July 9 and witnessed an elaborate program of aerial acrobatics arranged for their special benefit by the officials of the Atlantic City Airport.

The main event of the day was a spectacular demonstration of aerial mail dropping by means of parachutes from a speeding aeroplane.

To demonstrate with what ease and accuracy mail can be dropped over aerial mail stations or landing fields, Lieutenant R. L. Dunn, late of the U. S. Army, piloted his Curtiss type aeroplane to a height of over 2,000 feet above the Airport, with two parachutes, each having attached a twenty-five pound weight, representing the average bag of mail, and Mr. R. E. Shinn, one of the assistant secretaries of the Airport released the parachutes, which landed perfectly within a hundred feet of the spot selected. The remarkable value of this demonstration lies in the fact that this was Mr. Shinn's first flight in an aeroplane, and he had absolutely no previous experience in handling parachutes of any kind. This proves the efficiency of this means of delivering mail and demonstrates clearly the accuracy with which present day types of parachutes can be handled by even those inexperienced in their use.

The huge delegation of Elks was very enthusiastic over the entire program, and over 250 made flights over the city after the program was completed.

A view from above, showing the comfortable seating arrangement for 4 passengers in the "Airco 16" aeroplane

Flyers in Four Machines to Survey Million Acres of Labrador Timber

A commercial aerial expedition that will revolutionize the work of forestry survey and land photography, according to its managers, was announced by Captain Daniel Owen, until recently of the Royal Air Force. He said a fleet of four aeroplanes would leave Battle Harbor, Labrador, under his command, and would survey one million acres of forest and timber land along the coast of Labrador. The work is being done for a syndicate of Boston bankers.

A steamship left Annapolis, Nova Scotia, carrying forty men, who will comprise the aeroplane expedition. Captain Owen also went to Battle Harbor. The four aeroplanes are awaiting the force there.

"This has never been attempted before," Captain Owen said. "We will do as much work in this way in six days as we could do in the regular way in four or five years. All of the pilots excepting myself will be Americans recently discharged from the United States Army. The planes will be Canadian training machines."

A staff of physicians, headed by Dr. Irwin Tiss, of Ashland, Mass., will accompany the crew, with a full commissariat.

AERO CLUB OF AMERICA AND QUEENSBORO CHAMBER OF COMMERCE EXTEND LUNCHEON TO NC FLIERS

At the luncheon given by the Aero Club of America and the Queensboro Chamber of Commerce, at the Waldorf, on July 10, the Gold Medal of the Club was presented by Mr. Alan R. Hawley, President, Aero Club of America, to Lieutenant-Commander Albert C. Read, U. S. N., for the first trans-Atlantic crossing by air, and the Aviation Medal of Merit of the Club was given to the commanders of the NC-3, Commander John H. Towers, U. S. N., and Lieut.-Comdr. P. N. L. Bellinger, U. S. N., Commander of the NC-1 and to the members of the crews of all of three flying boats.

The Honorable R. A. C. Smith acted as Toastmaster and among those present were: His Excellency the Baron d'Estournelles de Constant and his son, Lieut. Paul d'Estournelles de Constant; Brig. General L. E. O. Charlton, British Air Attache; Lt. Col. W. Lucas, R. A. F.; Lt.-Comdr. Zachary Lanedowne, U. S. N.; Alan R. Hawley, President of the Aero Club of America; Comdr. John H. Towers, U. S. N.; Lt.-Comdr. A. C. Read, U. S. N.; Lt.-Comdr. P. N. L. Bellinger, U. S. N.; Glenn H. Curtiss, Congressman F. H. LaGuardia, Capt. Carlo Tappi, Italian Air Mission; Hon. Samuel Fairchile, Hon. Maurice Connolly, Borough President; Frederick A. Wallis, Fourth Deputy Police Commissioner; Colonel G. C. Brant, Admiral B. A. Fiske, Henry Woodhouse, Chas. Jerome Edwards, Augustus Post, Professor Chas. Lane Poor, Capt. R. A. Bartlett, Capt. Pierre Bosc, French High Commission; Col. Jefferson DeMont Thompson, Chairman, Luncheon Committee; Robert Graves, V. I. Brandon, Richard Wightman, William Morrow, G. Douglas Wardrop, Evan J. David, Norman E. Jennett, H. B. Childs, E. V. Hazelton, G. F. McLaughlin, etc.

Lieutenant-Commander A. C. Read recounted the thrilling experiences which he went through on his epoch marking flight.

Commander John H. Towers and Lieut.-Comdr. P. N. L. Bellinger both related the story of their experiences and His Excellency the Baron d'Estournelles de Constant, of the French Senate, President of the Aviation Committee of that body, spoke about the recent developments in European aeronautics and how much the crossing of the Atlantic has assisted enthusiasm for establishing transportation lines throughout the world.

The Honorable Fiorello LaGuardia, Member of Congress and Major in the Air Service, spoke about the great future for America in the air and the need of wise legislation to control and to speedily develop this great agent for the good of civilization.

The AIRCRAFT TRADE REVIEW

Curtiss Secures Large Order

The largest peace-time order for aeroplanes was placed recently by the Curtiss Aeroplane and Motor Corporation with its Buffalo plant.

The order calls for the building of 225 planes—both land and water—and 200 motors. One hundred and fifty of the planes will be the new Curtiss Orioles, the new three-passenger land machine which has already attracted world-wide attention, and seventy-five Curtiss Sea Gulls, the MF boat equipped with a higher-powered motor and changed in hull construction to admit of two passengers and a pilot. The motors are the new Curtiss 150 horse power motor. These motors, which will be the motor equipment for the Orioles and Sea Gulls, have a fuel consumption performance which has been demonstrated at one-tenth of a cent per mile.

Work upon the order will be begun at once at the Churchill plant of the Curtiss Aeroplane and Motor Corporation, which has been placed upon a production basis, and it is expected that a working schedule of one plane a day will be in operation in the near future.

The Oriole, announced by the Curtiss company during the month of May, proved a sensation. Before the second machine was completed, the sales department in New York had received orders for more than 100 from customers all over the United States.

The Curtiss Corporation now has distributors organized in all sections of the United States, and on August 9 C. W. Webster, supervisor of South American sales, will leave with a mission to tour the South American countries for the purpose of demonstrating American-made planes and, at the same time, to stimulate and promote aviation in general. He will take with him several of the best known pilots in the country and also the latest models, including the Oriole, Sea Gull, Hornet, the fastest two-place fighting plane, together with the OX-5 motors and the new Curtiss 150 and 400 horse power motors.

Bossert Cleveland Office

The Bossert Corporation of Utica, N. Y., sheet metal stamping specialists, has opened an office in Cleveland at 611 Citizens Building. W. W. Visy, Western sales manager, is in charge.

Huge Dirigible Proposed

At a conference of engineers and shipbuilders at Newcastle, England, Sir Charles Parsons predicted that an airship would be built soon of 8,000,000 cubic feet capacity, four times the size of the R-34, and capable of making a 15,000-mile non-stop journey. He added that a large flying boat was to undertake such a voyage from England to the Cape of Good Hope, crossing Africa from north to south and utilizing rivers and lakes as landing places if need be.

Bruce Eytinge and Chin Y. Chong, a Chinese whom he taught flying at Central Park, L. I.

American Importers Order British Linen

American importers of Irish linen have received information from London that the 30,000,000 yards of aeroplane linen, which was recently sold to an English trader for £4,000,000 was made up of widths running from 25 to 72 inches. The goods which comprised the complete surplus stock held by the British government, were disposed of on the basis of 2 shillings, 8 pence a yard. Belfast mill owners offered to buy the stock at 3½ pence a yard. The quantity sold is about three-fifths of the yearly output of the Belfast looms under normal conditions.

Long Island School Acquires New Field

Business at the Long Island Aviation Co. field at Central Park, L. I., has increased to such an extent that another field has been opened at Massapequa nearby, so that the passenger carrying work would not interfere with the regular course of instruction.

The location at Central Park is ideal for a flying school site, inasmuch as it is within an hour's ride of New York City, surrounded by miles of the most excellent terrain in the East. The field itself is one and a half miles long by a half mile wide, and perfectly level.

The aeroplanes used at the Long Island Aviation School are the Canadian training planes, JN-4 Type, equipped with dual controls, so that the novice is safe in the assurance that the skilled pilot can take control of the plane at all times. The Miessner aerophone facilitates the work of instruction. Students are given additional training in the working and construction of aeroplanes.

INTERNATIONAL AIRCRAFT STANDARDS COMMISSION ORIGIN

DURING the war, owing to the necessity for rapid production of aircraft and the common shortage of material, it was considered advisable to nominate an Inter-Allied Commission to study the question of the standardization of aircraft materials and components internationally. This Commission was authorized by the Allied governments and is composed of national committees appointed in the chief Allied aircraft manufacturing countries, namely, Great Britain, France, United States, Italy and Canada. Its organization is regulated by a set of statutes which have been agreed to by those co-operating in the work. The first meeting was held in London in March, 1918, and was opened and addressed by Mr. Winston Churchill, then Minister of Munitions; Lord Weir (then Sir William Weir, Director General of Aircraft Production, later Air Minister) and others being present.

Aims and Objects

A second meeting of the International Commission, on this occasion presided over by Sir Arthur Duckham, K. C. B., Director General of Aircraft Production, was held in October, 1918, when it was decided that when the war ceased the work of the Commission should not be allowed to terminate, but should be continued on a peace basis, with the following aims and objects:

(a) To study and recommend the industrial and technical standards best suited to the effective and rapid construction of aircraft, with the maximum standardization of material, specifications and interchangeability of component parts and the minimum of maintenance cost.

(b) To keep abreast of all inventions and progress by constant and periodic revision of the standards recommended.

(c) To secure approval and government acceptance of the "International Aircraft Standards" issued by the Commission.

National Committees

The Commission at present consists of six national committees representing the following countries:

Canada	Italy
France	Japan
Great Britain	United States

At the October meeting mentioned above the statutes were revised so as to permit the eventual co-operation of other countries in the work of the Commission with the advent of peace.

Any country, therefore, which does not already participate in the work of the Commission and desires to do so has the right to make application for membership to the Central Office for consideration at the next plenary meeting, but can only take part in the work subject to the approval (four-fifths of the votes received) of the Commission in plenary meeting.

The report of the October meeting, 1918, (A. C. N. 61) gives in detail the various subjects which were considered at that time as being susceptible to early international agreement. Eleven inter-

New York-Cleveland Mail 3½ Hours

The aero mail was run on July 8 from New York to Cleveland in 3 hours and 38 minutes, running time. The average speed was 119 miles an hour for the entire distance of 430 miles, the flight being with a De Haviland plane of 400 h.p. The first 215 miles from New York to Bellefonte, Pa., was made in 1 hour and 28 minutes, and the second leg, from Bellefonte to Cleveland, 215 miles, in 1 hour and 50 minutes.

The Aero Mail Service employed two extra planes on July 4th, making ten planes in the flight on that day. At the request of citizens of Chicago and Toledo stops were made and mail taken on at Toledo. The shortest of the ten aero mail trips, made on the 4th, was 215 miles, and the longest 325 miles. Every plane arrived and departed on time, with no forced landings, making a perfect score.

Excellent Aero Mail Record for June

A record of 99 per cent was made by the Aero Mail Service between Washington and New York for the month of June, covering a mileage of 11,118 and carrying 15,643 pounds of mail.

On the Cleveland-Chicago division a perfect score of 100 per cent was obtained. A total of 19,825 miles was run during the month of June on that division and a total of 19,603 pounds of mail was carried. The average speed on that route for the month was 97.8 miles per hour. The best flying was performed on June 18, when the round trip from Cleveland to Chicago and return was made in 6 hours and 14 minutes—an average of 104.4 miles an hour in each direction.

The operation of the Cleveland-Chicago route is without a parallel in the history of aviation. The route was started May 15 and has never missed a day—70 consecutive, daily, non-stop flights of 325 miles each were made without a forced landing. On the 71st trip a gas line connection sprung aleak, causing a forced landing on the emergency aero mail landing field at Bryan, Ohio. On all this flying the Liberty engine itself has never failed a pilot in the air.

The route from New York to Cleveland across the Alleghany Mountains has been operating with the same degree of perfection as the Cleveland-Chicago route since July 1.

On July 4 there were on the mail route between Washington and New York, New York and Cleveland and Cleveland and Chicago ten planes in flight. The shortest route was 215 miles from New York to Bellefonte, Pa., and the longest route was from Cleveland to Chicago, or 325 miles. All ten planes scored 100 per cent, arriving and leaving every station on time.

Three Radio Stations to Guide Aircraft Along Mail Lines

The Post Office Department has contracted for the erection of three high-power radio stations, the first of a chain of wireless communicating centres in various cities to be used primarily for the direction of mail-carrying aeroplanes handicapped by fog, it was announced by Emil J. Simon, manufacturer of radio apparatus for the War and Navy Departments.

Stations will be established at Bellefonte, Pa., and Cleveland, Ohio, with a third at some point on Long Island or at Newark, N. J. Appropriations for them already are available. Others will be erected at Washington and Chicago as soon as Congress provides funds.

Each station will be equipped with steel towers 200 feet high and 300 feet apart and will have a range of approximately 400 miles to mail aeroplanes and approximately 700 miles between stations, the difference in range being due to the lesser sending ability of aeroplane wireless equipment.

Establishment of the radio stations will enable the Post Office Department to maintain communication between cities having air post delivery independent of telegraph and telephone services in the event of a disruption of service by storms or other causes.

OTTO PRAEGER, Second Assistant Postmaster General.

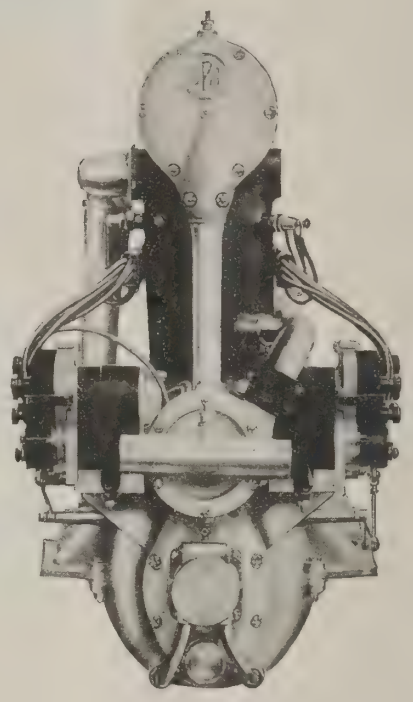
THE ANSALDO 1 BIPLANE

THE Italian "Ansaldo 1" Single Seater was built as a result of the comments of pilots at the front, who convinced the constructors of the S. V. A. aeroplane that the latter machine was essentially a long distance plane adapted to endurance and speed, but not possessing the extreme rapidity of climb and manouevring flexibility required of a pursuit plane, which must at all times be ready to climb quickly to all altitudes to engage in defensive combat.

The good results obtained by the combination of the S. P. A. engine and the S. V. A. aeroplane led the builder to devise a new type, in which the good qualities of the S. V. A. could be retained but the size and weight reduced and the carrying capacity limited to 2½ hours' fuel with a resulting increase in the characteristics desired. After a number of experiments in this direction, the "Ansaldo 1" (better known by its nickname of "Balilla," the popular Italian hero) was produced. In this machine the wing spread is reduced, and upper and lower planes are similar in size. The moment of inertia is reduced because the engine and pilot have been brought nearer the center of gravity and the tail shortened. The small wing spread makes it possible to employ but two struts on each side, braced by diagonal cables.

General specifications of the "Ansaldo 1" Single Seater and the S. P. A. engine are as follows:

General Specifications



Span, upper plane	25'-0"
Span, lower plane	21'-8"
Chord, both planes	5'-0"
Gap, between planes	4'-8"
Overall length	21'-8"
Overall height	10'-6"
Engine, S. P. A. Ansaldo	220 H.P.
Speed	145 M.P.H.
Climb in 16 minutes	16,000 Ft.
Climb in 25 minutes	20,000 Ft.
Useful load	550 pounds
Normal flight endurance	3 hours

Engine

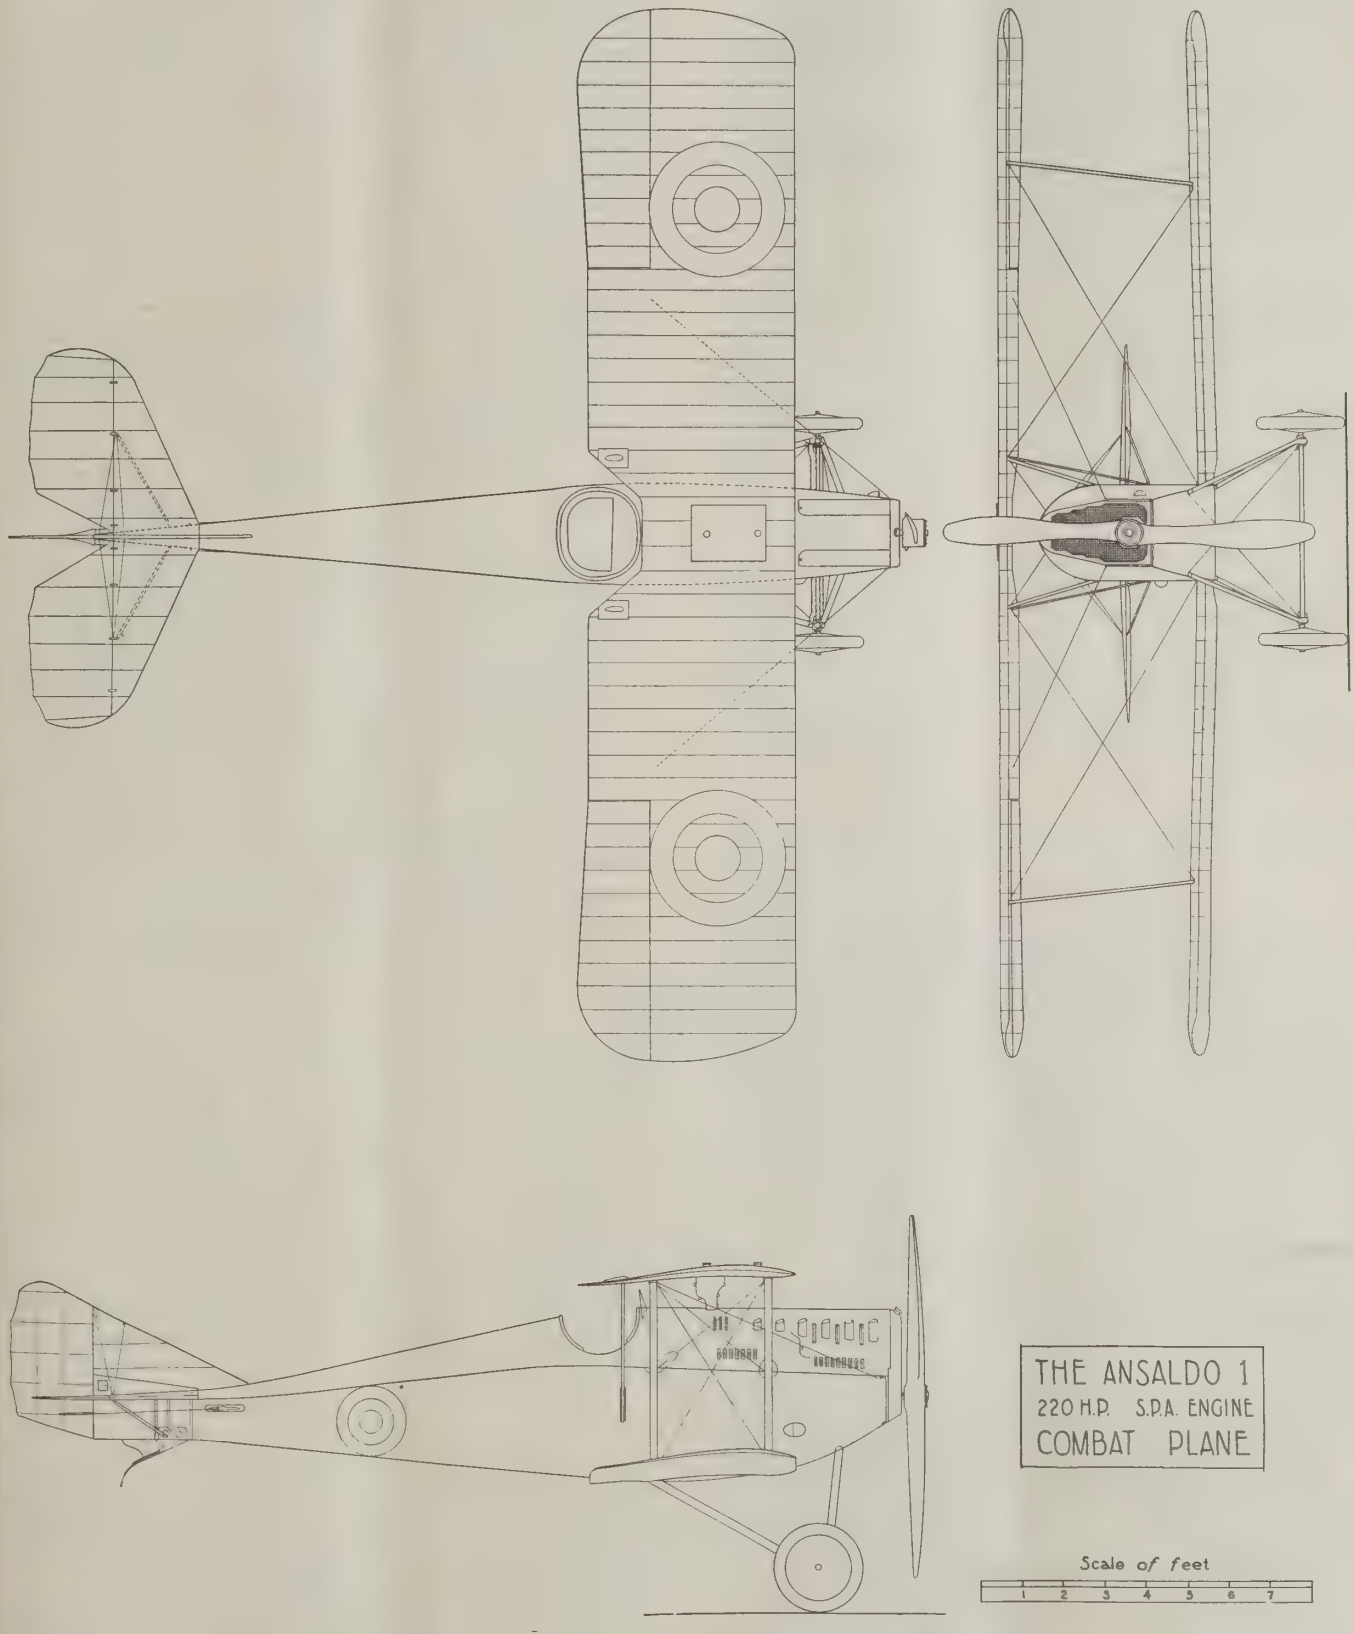
Power at 1,500 r.p.m.	190 H.P.
Power at 1,600 r.p.m.	210 H.P.
Power at 1,700 r.p.m.	225 H.P.
Number of cylinders	6 vertical
Bore	135 mm. (5-5/16")
Stroke	170 mm. (6-11/16")
Weight, including water	550 pounds
Fuel consumption per hr., at 1,700 r.p.m.	17.5 gals.
Fuel consumption per hr., at 1,500 r.p.m.	16. gals.
Oil consumption per hour	6 pounds

Main planes are equal in span. Upper planes in single section and lower plane in two sections, one at each side of the body. Above the fuselage an auxiliary fuel tank is built into the upper wing.

Ailerons are operated by a rigid system of control, with steel tubes running through the wing to vertical rods connected to the control column.

End view of the 6 cylinder 200 H.P. S.P.A. engine

Fuselage is covered with thin mahogany veneer. The forward part in the vicinity of the engine is covered with sheet aluminum. The shape of the fuselage is unusual. At the wings, body is of the usual rectangular section, but aft of the pilot's seat, the two lower longerons merge with one another and run straight back to the rudder. This gives the rear part of the fuselage a triangular section with, of course, the rounded turtle deck on top. This shape has proven to give very satisfactory results from an aerodynamic point of view, while constructionally the triangular trussing has many structural points of advantage.



The elevators are operated by a short pressed steel lever enclosed in the fuselage, doing away with exposed operating cables. A small inspection door is located in the fin to permit examination and adjustment of the lever. Rudder is operated by a pair of hardwood levers located below the elevators. The elevator is supported from below by a pair of steel rods from the fuselage and two pairs of solid steel wires from the fin.

The tail skid is a three-leaf steel spring, attached to the underside of the fuselage by flat steel plates and faired by hardwood blocking.

To eliminate fire risk, the main fuel tank located just forward of the pilot can, in an emergency, be instantly released from the machine by pulling a cable located within the pilot's easy reach.

Three-quarter front view of the Italian "Ansaldo 1" combat aeroplane. With a 200 H.P. S.P.A. engine the "Ansaldo 1" makes a speed of 145 miles an hour

THE VALUE OF SUPERCHARGING

A TEST has been carried out at the Altitude Laboratory of the Bureau of Standards to discover the results of increasing the carburetor air inlet pressure above the exhaust back pressure of an aeroplane engine, and to evaluate the effect of this upon the horsepower output.

The results of this test show what gain in horsepower may reasonably be expected through supercharging, and indicate that a net gain in horsepower will result even if considerable power is needed to drive the blower.

The engine under test is enclosed in a chamber the air pressure in which may be controlled independently of that on the carburetor inlet, by means of suitable pipes and valves leading to the atmosphere and to a suction blower.

A stock 150-horsepower Hispano-Suiza engine, built by the Wright-Martin Aircraft Corporation, New Brunswick, N. J., having a compression ratio of 5.3 to 1, was used in making the tests. The Claudel carburetor with which the engine was equipped was adjusted in each case to give maximum power.

Two runs were made with approximately a constant pressure on the carburetor, and with varying exhaust back pressures in each case. The first run was made with the valve on the intake wide open, so that the highest pressure could be obtained on the carburetor. The pressure within the chamber, which is the same as the exhaust back pressure, was adjusted and readings taken at values of approximately 62, 50, 38 and 34 cm. Hg. The data obtained are listed in Fig. 1, and the results are plotted as Curve "A" in Fig. 2.

Figure I—Table of Data on Test 108

Barometric Pressure. Cms. of Hg.	61.9	49.7	37.5	33.9	33.1	37.7	50.0	62.1
Pressure at Carburetor Intake. Cms. of Hg.	72.67	71.42	71.12	70.22	55.22	55.22	55.22	55.22
Horse Power Corrected to O°C and 1500 RPM	170.2	171.3	173.4	171.8	132.9	129.6	125.4	122.0
Lbs. of Gasoline per Horse Power per Hour	.584	.593	.573	.580	.567	.545	.554	.559

In the second run, the valve on the intake was partially closed, so that the pressure on the carburetor was the equivalent of 20 cm. Hg below the prevailing atmospheric pressure, and readings taken at approximately the same points as before. The results of this run are given in the second half of Table 1 and are plotted as Curve "B" in Fig. 2.

In the first run the pressure of the intake air was not constant throughout, varying from 72.67 to 70.22 cm. Hg, so that it was necessary to correct the results to some constant pressure. The correction was made to a pressure of 70 cm. Hg by interpolation, which is based on the assumption that the increment of horsepower developed at a given back pressure is proportional to the increment of pressure of the carburetor air. This correction gave Curve "C" in Fig. 2. All horsepowers were corrected to 1500 r.p.m. and O° C. This temperature correction was made in accordance with the results of a series of tests performed in this laboratory to determine the variation of horsepower with temperature.

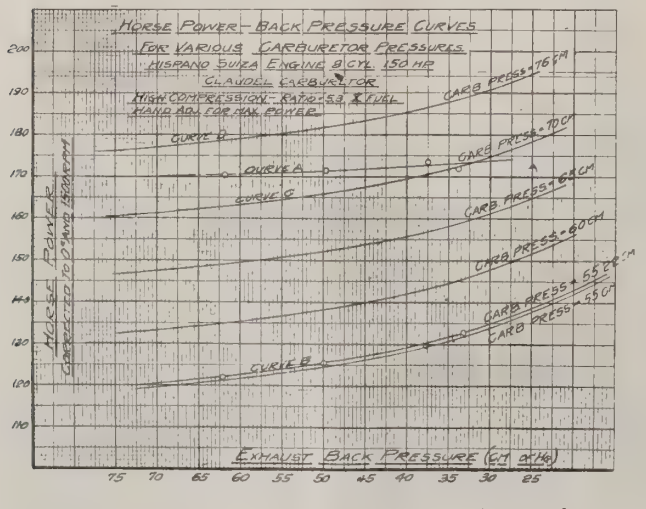

Figure 2—H.P. back pressure curves for various carburetor pressures

In order to determine the engine performance under different conditions of carburetor pressure and exhaust back pressure, a family of curves at carburetor pressures of 76, 70, 65, 60 and 55 cm. Hg were plotted against the exhaust back pressures. These were derived from the two experimental curves by interpolation based on the assumption as mentioned above.

As it is desirable for purposes of design to know the engine output under different conditions as a function of the maximum output on the ground, the ratio of horsepower taken from the above-mentioned curves to the horsepower at a carburetor and exhaust pressure of 76 cm. Hg, taken from Curve "D," is computed and plotted in Fig. 3. These curves give the engine performance under the different conditions on the basis of a constant temperature of air at the carburetor.

To compute the horsepower that would be developed by an engine equipped with a supercharging device, under a given set of conditions of altitude, carburetor air pressure and exhaust back pressure, knowing the engine performance on the ground, we may make use of the above-mentioned curves in connection with the following relations:

$$HP = HP_1 \times R \times (F_2)_1 \qquad (1)$$

in which HP = horsepower developed with the supercharging apparatus at the given altitude, and HP_1 = the observed horsepower on the ground at the observed carburetor air temperature of t_1, and R = horsepower ratio at the given conditions of exhaust and carburetor pressures produced by the supercharging device at the given altitude (obtained from curves in Fig. 3), and $(F_2)_1$ = temperature correction factor to correct from observed temperature on the ground; t_1, to temperature at the carburetor; t_2, under the given conditions.

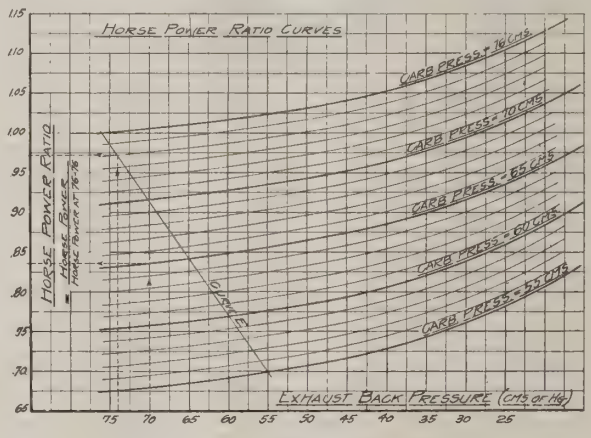

Figure 3—Horsepower radio curves

The use of any form of supercharging device involves a compression of the air from the prevailing atmospheric pressure at the given altitude, to some higher pressure, before entering the carburetor. This results in a heating of the air above the prevailing temperature of the atmosphere, and a consequent reduction of the available output of the engine. (For average temperatures of atmosphere at various altitudes see Curve "B" on Sheet 6.) The temperature resulting from such a compression may be computed by the use of the equation:

$$T_2 = T_1 \left(\frac{P_2}{P_1}\right)^{\frac{n-1}{n}} \qquad (2)$$

in which T_2 = temperature at carburetor after compression (absolute) and T_1 = temperature of the atmosphere before compression (absolute); and P_2 = pressure at the carburetor after compression; P_1 = atmospheric pressure at the given altitude (pressure before compression), and n = the compression exponent (1.41 for an adiabatic compression).

As the air entering the carburetor at the temperature t_2, after compression (corresponding to the absolute temperature T_2 of Equation 2) is in most cases different from the observed temperature on the ground, t_1, the temperature correction factor $(F_2)_1$ must be included in Equation 1 to give the correct output that would be developed at the existing air temperature at the carburetor under the given conditions.

To facilitate computations, charts were constructed in Figs.

4 and 5 for obtaining the temperatures after compression, t_2, according to Equation 2, and the temperature correction factor $(F_2)_1$ respectively.

In using the chart for compression temperatures it is unnecessary to determine the temperature of the altitude, as this is a function of the altitude barometric pressure, and is incorporated into the chart. To use this chart, locate carburetor pressure on the horizontal scale at the bottom, trace vertically upward to the line of barometric pressure corresponding to the given altitude, then horizontally to the curve of the desired compression exponent. From there trace vertically upward or downward to the line corresponding to the barometric pressure of the altitude, and horizontally to the right to the scale of temperatures. This gives the temperature after compression in degrees C.

The temperature correction factor $(F_2)_1$ may be obtained from the chart in Fig. 5. To use this chart, locate the observed temperature on the ground, t_1, on the horizontal scale at the bottom, and trace vertically upward to the line corresponding to the compression temperature as obtained from chart in

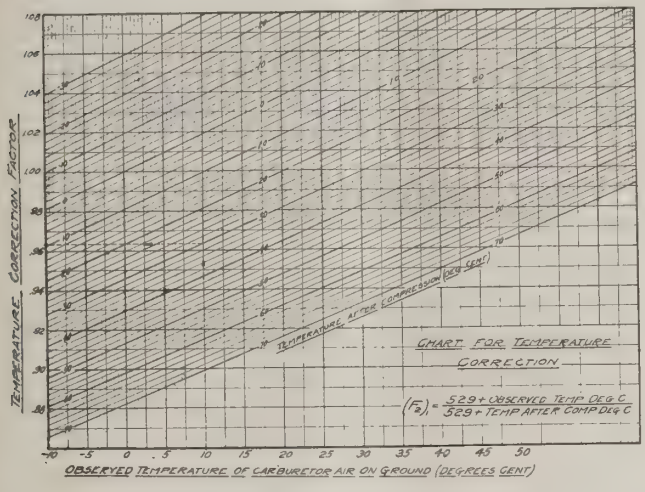

Figure 5—Chart for temperature correction

Fig. 4. From there trace horizontally to the line of correction factors.

An example may serve to illustrate the use of the curves and charts. Assume that an engine capable of developing 400 horsepower on the ground at a temperature of 10° C. (50° F.) is to be equipped with an exhaust pressure turbine blower, which at a barometric pressure of 35 cm. Hg (corresponding to 21,100 feet altitude and a temperature of — 21° C.) (see curves "A" and "B" in Fig. 6) exerts a back pressure on the engine of 35 cm. Hg and increases the carburetor pressure by 30 cm. Hg. Then we have for the exhaust pressure on the engine at a given altitude 35 + 35 = 70 cm. Hg and for the carburetor pressure we have 35 + 30 = 65 cm. Hg. From the curves in Fig. 3 we obtain a horsepower ratio of 0.836. To obtain the temperature after compression we may assume an adiabatic compression with an exponent of 1.41, and from the chart in Fig. 4 obtain a temperature after compression of 30° C. From the chart in Fig. 5 we obtain the temperature correction factor to correct from 10° C. to 30° C. = 0.963. Substituting these values in Equation 1 we obtain for the horsepower at 21,100 feet, with exhaust pressure turbine blower supercharging equipment:

$400 \times 0.836 \times 0.963 = 322$ HP.

If a geared blower were used, then in obtaining the horsepower ratio the barometric pressure at the given altitude

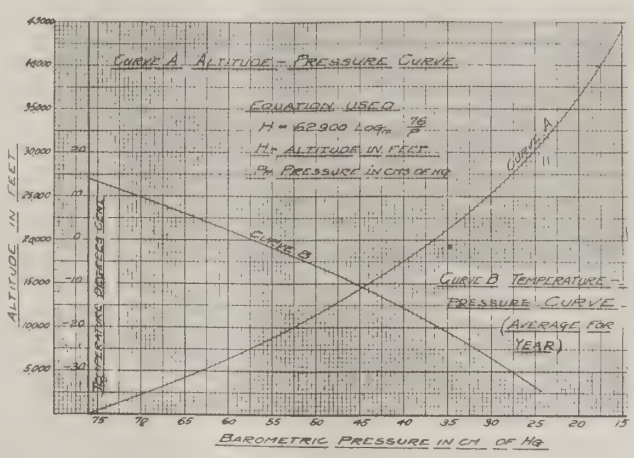

Figure 6—Altitude and temperature pressure curves

would be used as the back pressure on the engine; and from the available output computed on this basis the power necessary to drive the blower would be deducted.

If it is desired to include, as a further refinement in the above computations, a correction to the observed horsepower on the ground, HP, for barometric pressure, the output as computed by Equation 1 may be multiplied by a pressure correction factor obtained from Curve "E" in Fig. 3, as follows:

Locate the intersection of Curve "E" with the curve of carburetor pressure corresponding to the observed barometric pressure on the ground, trace horizontally to the left and read horsepower ratio. The barometric pressure correction factor is 1 divided by this horsepower ratio.

An illustration will serve to make clear the use of this correction factor. Assume that in the above example the observed horsepower (400) was obtained at an observed barometric pressure of 74 cm. Hg. From Curve "E" we obtain, by the method described above, a pressure correction factor of

$\frac{1}{.972}$ (see Fig. 3) = 1.03. Applying this to the horsepower obtained, we get

$322 \times 1.03 = 332$ HP.

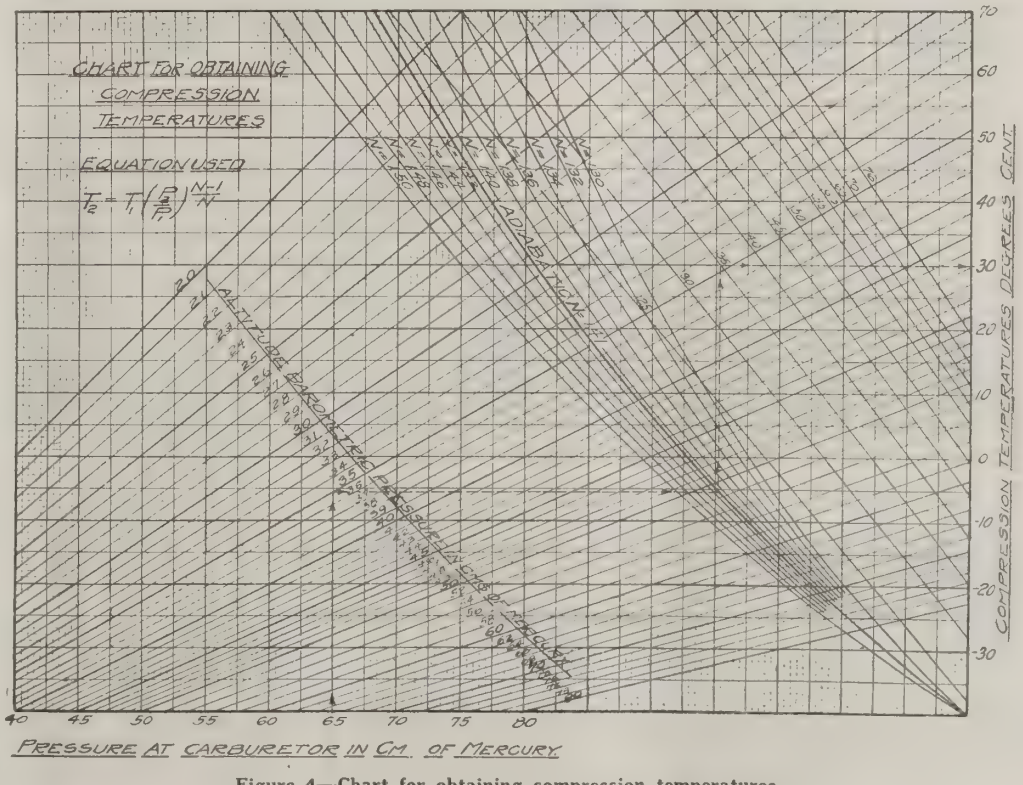

Figure 4—Chart for obtaining compression temperatures

A PORTABLE HANGAR FOR AEROPLANES

SINCE aviation became a scientific demonstration instead of a theory, it has been the endeavor of aviators and engineers to construct a portable aeroplane hangar that would combine ample working space without waste of material, strength of wind resistance sufficient to withstand storms even when they approach cyclonic velocity, and ease of egress and ingress.

During the war the Aviation Section of the War Department made numerous experiments along this line with indifferent success. Severe tests of a newly designed portable hangar of this kind were made last week at the U. S. Flying Station at Hazlehurst Field, Mineola, L. I., under the supervision of Major J. E. Rossell, Engineering Officer of the Army Air Force stationed there. The hangar, manufactured by Foster & Stewart Co., was erected in a gale of wind and stood up against a heavy rain storm that came up during the night.

These wind-proof hangars are easily transported from field to field, and can quickly be erected by the crew of the machine it is built to protect. They are standardized for the various makes of planes, and are particularly suitable for the JN-4 type Curtiss.

The width of the hangar is 51 feet, which allows 3½ feet on each side to the tips of the plane. The walls of the main body of the tent are 12 feet, allowing ample clearance space for the ingress and egress of the plane, yet making the highest point of wind resistance only 13 feet. At this point the hangar is protected by a double set of guys which are built into the tent, and which criss-cross themselves in a manner to balance the strain, no matter from what direction the wind may blow. There is nothing to unfasten or to become unfastened, as these guys, passing as part of the top completely over the hangar, are fast to the rings the poles go in. The extension to accommodate the fuselage is of ample size to allow working room, and is designed at an odd slant to shed wind and water. It is guyed just as substantially as is the main body of the hangar.

The detail of the construction is simple. Likewise the method of erection. All that is necessary is to spread out the tent, and put it up. The JN-4 hangar can be erected by two men in a short time.

When the tent is up, the front wall is tight, but is attached to a cable at the top, and can be opened from the center, portiére style, for the ingress and egress of the plane. When close, these center pieces are lashed together, making it to all intents and purposes a continuous piece of canvass. Iron pegs at the bottom secure the front to the ground.

The width of the hangar is such that there is ample room for cots or camp beds under the tips of the upper planes, and the walls are so made that they can be rolled up six feet and then firmly lashed, giving air from all directions.

This hangar first was erected the Sunday previous to the Government inspection on the flying field of the Hotel Nassau, at Long Beach, L. I., where former Lieuts. Lyman B. Lockwood and Edward K. Merritt have established a passenger carrying business.

The specifications of the JN-4 Curtiss hangar, are as follows:

The total width of hangar is 51 ft., and depth 39 ft. The dimensions of plane space are: 51 ft. width by 17 ft. 2 in. in depth, and the height to the center, 20 ft. Walls and front are 12 ft. in height.

The dimensions of the extension to accommodate the fuselage are 16 ft. 6 in. deep, the wall at the right being 12 ft. in height, and on the left 7 ft. in height. The wall of the tent on front, sides and ends is constructed to roll to height of 6 ft. and to lash to allow a free circulation of air.

The top is made of 12-oz. khaki, all hand roped with 9/16-in. and ½-in. diameter manila rope. All walls and ends are of 8-oz. double filled khaki with wind bands for strength throughout; all hand-roped at ends and bottom. The bottom of the ends and walls are equipped to snap to iron pins 12 inches long with an eye, and the front wall to snap to cable 3/16 in. diameter with two turnbuckles. The front wall is to slide from center to ends, and the front is lashed to ½-inch diameter cable with two turnbuckles and ropes to pass through thimbles to prevent chafe.

All guys of manila rope 9/16 in. in diameter are fastened to tent, and are non-detachable. All lanyards are of ¼-in. manila rope, and all 12 and 7-ft. pole lanyards are of 5/16 in. manila rope. All lacing holes are No. 4 sheet brass grommets, and all holes to receive poles on lower edge of tent are round galvanized thimbles, preventing chafe to any rope. All other pole holes in upper part of roof are of drop forge rings, hand-worked in and leathered to protect ropes leading through the bottom of tent to rings.

Poles: two, each 20 ft. long by 4½ in. in diameter; two, each 15 ft. long by 3½ in. in diameter; ten, each 12 ft. long by 3½ in. in diameter; two cable poles, 12 ft. by 5 in. in diameter with sheaves which cross pole 16 ft. 9 in. by 3½ in. diameter to lash fusalage end to.

Total stakes: thirty-eight, hickory wood, each 40 in. long, banded and painted.

Iron pins for bottom of wall and ends: forty.

Weight: Tent and wall, 530 lbs; stakes, 191 lbs.; cables, 122 lbs.; poles, 882 lbs.; total weight, 1,725 lbs.

A compact canvas hangar for a Curtiss JN aeroplane, erected at Hazelhurst Field, Mineola, for the purpose of testing it under severe weather conditions

THE GENERAL PROPERTIES AND USES OF PLYWOOD

By B. C. BOULTON, B.S., A.E.

PART III

(*Continued from page* 815)

THE ordinary thickness for the veneer in either the three- or five-ply construction is 1/32 in. for each ply. In general fuselage work the thickness of the core is usually about 50 per cent that of the plywood.

Beside the type of veneer fuselage which has just been described, another kind is being further developed, properly known as the monocoque type. A body of this character can be made almost perfect aerodynamically, owing to the fact that it can be built to conform to practically any contour desired. Structurally, a monocoque body acts like a shell. It is characterized by its rigidity and resistance to distortion. Though light longerons are used, they do not play a very important part in carrying stress. In the same way, the bulkheads in the rear portion of the body are reduced in number to about three, and serve solely to stiffen the structure. It is possible to build such a fuselage for a weight considerably less than that of any other type. Unfortunately, owing to the large amount of labor required in its construction, this type as yet is expensive. Methods may be evolved that will simplify the present process.

The general method of construction is as follows: First, a heavy wood form is built up which is the exact shape of the body. This is made in two symmetrical halves. When the form is ready, the work of putting on the veneer is begun. There are two general methods for building up the body. The customary process is illustrated by the well known L.W.F. fuselage and is quite reasonable in cost. With this type, thin veneer strips 4 to 6 in. in width are wound spirally about the form so as to make about one turn in the length of the body. After this first layer of veneer is complete, cloth tape some 2¼ in. wide is wound over the veneer in a continuous strip, lapped about ¼ in., and glue applied. Another layer of veneer is now laid, wrapped around the body in a spiral of the same degree, but opposite in direction to the first. On top of this comes a second layer of tape wound as before. The third and last layer of veneer is now applied with the grain longitudinal. After the structure has dried three or four days, the mold, which with this method of construction is not in two halves but is collapsible, is removed. One layer of Utica sheeting, applied to the outside of the body with dope, forms the finish. Spruce veneer has been found very satisfactory. A usual thickness is 1/32 to 1/16 in. In general, transverse sections of such a fuselage are symmetrical about two axes. It is not practicable with this type to form the veneer into sharp curves, and therefore the fairing of the lower wing into the body, or the construction of the fin integral with the body, is very difficult.

The second general method carries out still further some of the principles involved in the construction just described. It is probable that better results in every way can be obtained in a body built according to this later process. However, on account of the amount of labor entailed, it is a method not adapted to large scale production. Some important details are still being developed. In this process, the veneer in long, narrow strips not more than 2 in. wide is wound on each half form in a tight spiral of such degree that the strip makes an angle of approximately 45° with the longitudinal axis. These strips are crowded close together and are lightly tacked down to hold them in place. On completion of this layer, the second is begun. The strips now run at right angles to those forming the inside layer. As they are laid, Certus joint glue is applied between them and the first layer. Immediately, the strips are butted up close against each other and secured firmly in place by short, light nails every 4 or 5 in., driven through a little 1 in. cleat of plywood. After the glue has thoroughly dried these nails and cleats are pulled off, and the form is ready for the third layer of strips, laid with glue in the same manner as before and at right angles to the strips in the second layer. When this step is completed a fourth layer of strips is applied, again at right angles to the strips in the adjacent layer. On the drying of these last strips and the removal of the nails, each half the shell may be readily removed from the form and carefully trimmed along the joint lines. The two parts of the shell are now ready to be fitted together. The splice, which occurs at the bottom and top, is made by an inside, laminated keelson, 2 x 5/16 in. to which each half the shell is securely screwed and glued. The edges of the shell are butted together, thus forming a regular butt joint with a single cover plate. The last step in the process is the application of a layer of sheeting, which is put on with hot glue, and after drying is doped and varnished. The plies forming the shell are of soft wood like poplar or spruce, each ply being about 1/16 in. in thickness.

Bulkheads: In the forward part of the fuselage the bulkheads that support the engine and gasoline tanks, and receive stresses from the lift wires are of heavy construction. To secure maximum homogeneity a large number of plies, each of 1/16 or 3/32 in. thickness, is used. The total thickness of such bulkheads will ordinarily be between ¾ and 1 in. If great strength is desired, birch or maple veneer is employed, but on lighter work spruce is used successfully. It is common practice when the bulkhead is of spruce or some similar wood, to have all the plies of the same species of wood and of the same thickness, but frequently a combination of a strong, heavy wood and a light wood is advantageous.

Another more recent type of bulkhead which is much lighter

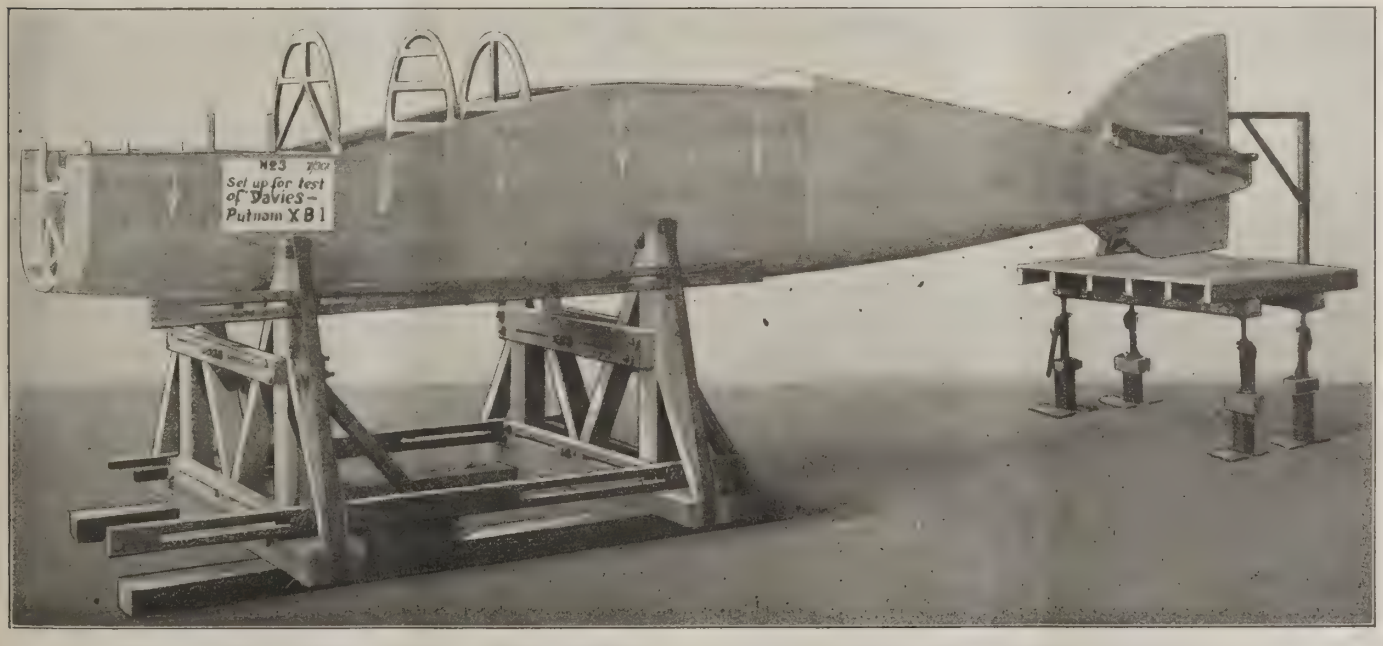

Fig. 9. Veneer Fuselage Complete, showing longitudinal and transverse Splices in Skin. Fuselage ready for Sand Test

than that just described is a form of built-up, truss construction, in which the stresses are carried by solid spruce members. These are connected, and built into one structure by two light sheets of three-ply veneer, which form flanges for the spruce columns, one sheet being glued to each face of the bulkhead. Reference to Fig. 10 will make the construction clear. The gains with this type of bulkhead are due to the smaller amount of glue necessary, and to the fact that, because all the grain of the compression members runs in the direction of the stress, the material is most effectively used.

TABLE 4

5	.67	6.6	25	14,700	6,800	13,100	8,600	143
7	.70	7.1	25	14,300	7,900	12,900	9,300	212

†Specific gravity based on oven dry weight and volume at test.
*Parallel and perpendicular refer to direction of grain of faces relative to direction of application of force.

In veneer fuselage construction, the bulkheads in the rear act principally as stiffening rings in preventing distortion of the skin. As they carry only these secondary stresses it is possible to make them light. Five-ply spruce of ⅜ in. total thickness, or five-ply mahogany and poplar of the same thickness, for instance, is suitable for most work. Fig. 8 illustrates some of the various features that have been discussed.

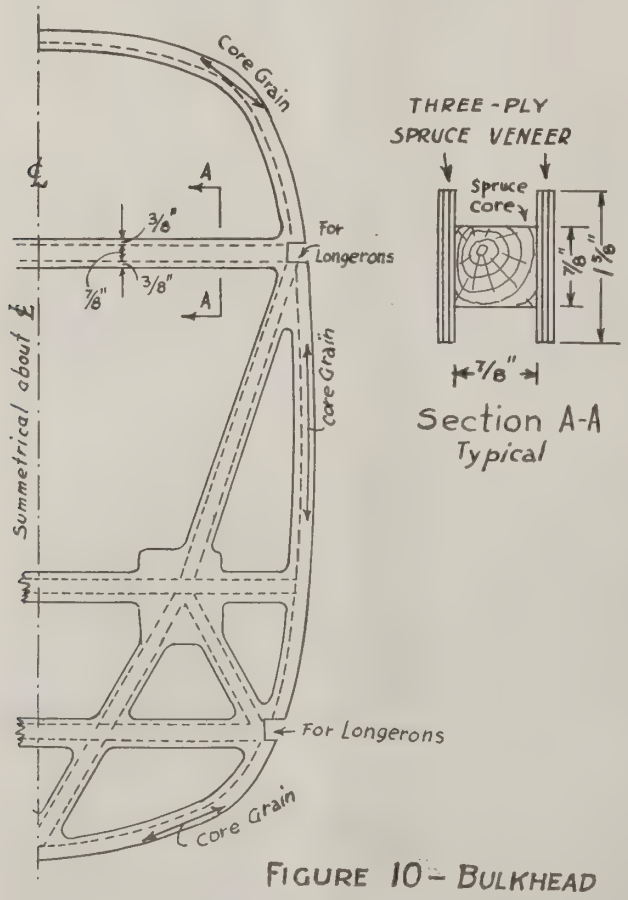

FIGURE 10 – BULKHEAD

Covering for Wings and Control Surfaces: Plywood, when used to replace fabric on aerofoils, has several advantages. One of these is the elimination of sag between ribs, this distortion being considered detrimental to the efficiency of the aerofoil. Another advantage is that with plywood there is but very slight possibility of its tearing loose from the wings, as sometimes occurs with fabric. Again, plywood braces and stiffens the wing structure, distributes the stresses and, if not too thin, adds materially to the structural strength of the wing, making it possible to omit internal drift bracing, and to reduce the size of the spars. On the other hand, the plywood may warp or wrinkle, though proper design and care in the method of application should prevent this trouble. Even the lightest plywood developed up to the present weighs at least 2 to 3 times as much as doped fabric. Probably the best, very thin plywood so far designed is constructed of Spanish cedar, and has a total thickness of 1/32 in. This makes it too thin to add directly to the structural strength of the wing. Its principal use would be on control surfaces, on the center section of the main wings, and on the upper surface of these wings from the leading edge back to the front spar.

Unless some great improvement occurs in the design of plywood for wing covering and in its application, it cannot be used on modern planes on account of its excessive weight.

Spars: Because of the shortage, during the war, of suitable spruce for spars, many experiments have been made to develop a plywood spar. No such section has ever approached the efficiency of the solid spruce spar. This is due to the large increase in weight caused by the glue. The best types of laminated spar produced are the box section, with solid spruce flanges and about 3/16 in. three-ply webs, and the I-section with solid flanges and a web of three, or possibly five, thick laminations. The utilization of material of small section and inferior quality is the advantage sought by the use of plywood in spars. It can, however, be more easily obtained in built-up spars than in laminated ones. Spruce is a material that is most commonly employed for spars, although birch is frequently used for the faces of the webs in box spars. The face plies in this type of spar have their grain horizontal. The total thickness of each web varies from ⅛ to ¼ in., depending on the depth of the spar, while the core thickness is about half this amount.

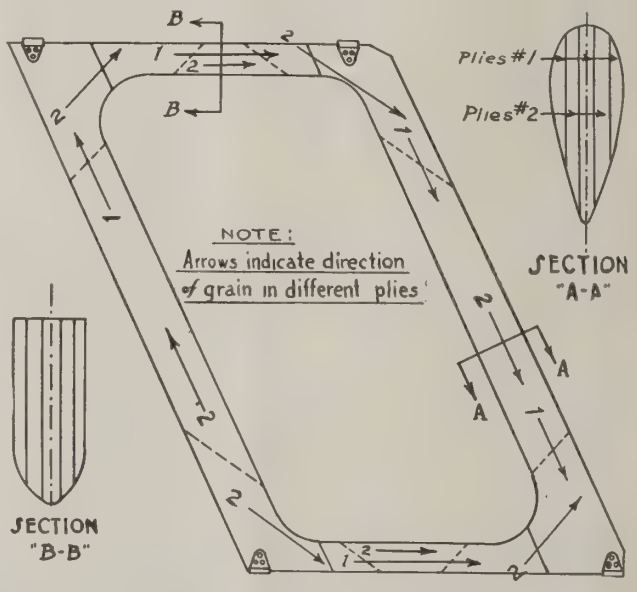

FIGURE 11 - Portal interplane strut

Struts: In order to minimize the effect of spiral or cross-grain in spruce, a laminated construction is sometimes used in struts. Since the grain of all the laminations runs in the

same direction, this type of structure is not plywood in the true sense. There are usually but 4 to 6 laminations, each being ¼ to ⅜ in. in thickness. The extra weight of these struts due to the glue is a disadvantage.

Certain kinds of strut frames, such as the "N" type for cabane struts, or the portal for interplane struts, which are capable of taking moment at the corners, and so may replace diagonal or incidence wires, are a combination of laminated and plywood construction. In each member of the frame, for the greater part of its length, the grain of all the laminations is parallel to the direction of the stress, but at the intersection of the members the laminations are dovetailed, producing a plywood construction in which the grain of the adjacent plies is nearly at right angles. A unit frame of this type has considerable rigidity, but is appreciably heavier than the usual combination of single struts and wires. From the military point of view, one of its chief advantages is its ability to transmit by torsion the load from either the front or rear lift trusses, should one of the trusses be shot away, to the uninjured truss. The elimination of drift and incidence wires reduces to a certain extent the air resistance, especially with high speed planes. Another advantage of considerable importance obtained with this type of bracing is the ease with which a wing cell may be aligned. The stagger of the wings, and the decalage, if there is any, is practically fixed. However, in case it is desirable to alter the stagger for some reason, this feature is a disadvantage.

(The writer wishes to acknowledge the value, in the preparation of this article, of certain reports issued by the Forest Products Laboratory for the Bureau of Aircraft Production.)

LIBERTY

A TRADE-MARK REGISTERED BY THE UNITED STATES OF AMERICA

By CAPTAIN WILLIAM L. SYMONS, AIR SERVICE, U. S. A.

A CERTIFICATE of registration of the trade-mark "Liberty" as used on aeroplane engines was granted by the United States Patent Office to the United States of America on June 17, 1919. This is the first instance of the Government of the United States registering a trade-mark under its own trade-mark laws, or the laws of any other country, although other governments have registered their marks in the United States Patent Office for the goods on which they are used. The Republic of France has registered marks used on cigarettes, and several registrations have been granted by the United States Patent Office to the Imperial Government of Japan. Some government activities, such as the War and Navy Department's Commission on Training Camp Activities, have been granted registration of their trade-marks.

Everything connected with the history of the mark "Liberty" as used by the United States on its aeroplane engines is unique. When the Liberty engine was first developed in the summer of 1917 it was referred to by the government engineers as the "United States Standard Aircraft Engine" or the "United States Standard Engine." Some genius, however, selected the right word and all the district offices of the Bureau of Aircraft Production, which was then the Equipment Division of the Signal Corps, were soon notified that the use of the word "Liberty" as applied to the new engine was so popular that it seemed inadvisable to attempt to use any other name. This word was a happy selection.

Trouble resulted in a short time, however, from the great popularity of the word "Liberty" as applied to articles of commerce. Many manufacturers began to designate their goods by the term "Liberty." This use of the term on goods which are of the same general class as engines or on goods adapted to be used on engines resulted in confusion and probably in deception. Government officials soon saw that it was necessary to protect the name. After considering several ways of getting the best protection of the right of the Government in the use of the word "Liberty," the plan of registering it in the United States Patent Office under the United States Trade-mark Law was adopted. These proceedings resulted in the grant of certificate of registration No. 125,853, which under Section 16 of the Trade-mark Act constitutes prima facie evidence of ownership of the mark "Liberty" as used on engines and parts thereof.

Personal Par

Lieut. E. D. Stearns, Aviation, has joined the H. K. Ferguson Co., Cleveland, as sales manager. Lieut. Stearns is a graduate of the University of Illinois, 1907. For several years after completing his engineering course, he was connected as engineer and erection superintendent for the Stephens-Adamson Co., and was later manager of its New York branch. For 6 years previous to his military service, he was a partner in the Ft. Pitt Engineering Co., Pittsburgh.

NAVAL and MILITARY AERONAUTICS

140,000 Miles Flown in June

The work of the Air Service of the United States Army for the month of June in cross-country flying totaled 140,000 miles. This did not include the mileage flying over fields in giving instructions to enlisted men.

Flying Circus of Seven Off On Flight to Texas

Hempstead.—Lieutenant Colonel Harry B. Claggett, who left Texas some time ago to fly to Boston on a recruiting tour of the Eastern States, left July 12 on the return trip to Texas with his flying circus of seven. The first stop will be made at Washington.

In the leading plane was Colonel Claggett as pilot, with Captain William H. Chandler as observer. Behind them come in order, Major John W. Simmons, pilot, with Sergeant Harry H. Altman as observer; Major Roy S. Brown, pilot, with Captain Herman Fluegel as observer; Lieutenant J. E. Duke, Jr., pilot, and Sergeant Wayne Wetzell, observer; Lieutenant Benjamin H. Adams, pilot, and Sergeant James C. Smith, observer; Major Henry J. F. Miller, pilot, and Lieutenant M. John Plumb, observer; Lieutenant Robert F. Medkill, pilot, and Sergeant Ralph Kratz, observer.

Night Altitude Flight

An experimental flight for altitude at night was conducted at Carlstrom Field, Arcadia, Fla., at 10 o'clock, July 10. Lieutenant Charles C. Chauncey in a Le Pere with Sergeant Thomas Cook, as passenger, reached an altitude of 20,000 feet without difficulty.

The weather was clear, the wind from the northwest, speed ten miles per hour, and the thermometer in the rear cockpit of the aeroplane registered five degrees below freezing point. The duration of the flight was eighty-five minutes. At 10:05 P.M. the two airmen observed a second sunset.

Army's Non-Stop Record

Announcement was made since early in April army fliers in this country have made eleven non-stop flights, each exceeding 500 miles. The longest was made by Major Theodore C. Macaulay and measured 852 miles. The fastest was made by Lieutenant R. S. Worthington, who covered 500 miles at an average speed of 166.62 miles an hour. In the same period army fliers have made several transcontinental flights and other long flights in which there were intermediate stops of less than 500 miles each. The record of the notable long non-stop flights is:

April 12. Theo. Macaulay and Sergeant A. W. Allman in a De Haviland-4, from Fort Worth, Texas, to El Paso, Texas, 580 miles, in 345 minutes; 100.86 miles per hour.

April 14. Theo. C. Macaulay and Sergeant A. W. Allman, in a De Haviland-4, from Tuscon, Ariz., to Sweetwater, Texas, 701 miles, in 345 minutes; 121.86 miles per hour.

April 16. Theo. C. Macaulay and Sergeant A. W. Allman, in a DeHaviland-4, from Fort Worth, Texas, to Americus, Ga., 852 miles, in 415 minutes; 123.18 miles per hour.

April 19. Captain E. F. White and H. M. Schaeffer in a De Haviland-4, from Chicago to New York, 725 miles in 350 minutes; 133.80 miles per hour.

May 4. Captain Roy N. Francis, Major W. H. Frank, Lieutenant Coe, T. E. Gilmore and Lieutenant E. E. Harmon, in a U. S. Martin bomber, from Washington to Macon, Ga., 650 miles in 470 minutes; 82.98 miles per hour.

May 17. Colonel G. C. Brant and Lieutenant H. Birkett, in a De Haviland-4, from Houston, Texas, to Belleville, Ill., 720 miles in 453 minutes; 114.8 miles per hour.

May 20. Lieutenant G. H. McKay, in a Curtiss JN-4H, from Belleville, Ill., to York, Neb., 500 miles, in 343 minutes; 86.04 miles per hour.

June 17. Howard Rhinehart and J. E. Talbot, in a De Haviland-4, from Dayton to Mineola, 502 miles in 250 minutes; 120.48 miles per hour.

June 17. Lieutenant R. S. Worthington, no passenger, in an SE-5, from Palo Alto to San Diego, 500 miles in 180 minutes; 166.62 miles per hour.

June 24. Lieutenant G. H. Palmer, Lieutenant G. E. Bradford, and five mechanics, in a Handley Page from Indianapolis to Washington, 505 miles, in 285 minutes; 106.26 miles per hour.

July 7. Captain Lowell H. Smith, no passenger, in a De Haviland Bluebird, from San Francisco to San Diego, 610 miles, in 246½ minutes; 148.44 miles per hour.

San Francisco-San Diego Record

A telegram has been received from San Diego, California, stating that Captain Lowell H. Smith, flying alone in a De Haviland "Bluebird," broke the non-stop speed record July 7 between San Francisco and San Diego by flying the distance of 610 miles in 246½ minutes, which is at the rate of 148.44 miles per hour.

Capt. Edward Laughlin, U. S. A., Engineer Officer at the Dallas Aviation Repair Depot

Lieut. Col. Netherwood, commanding officer of the Aviation Repair Depot at Dallas, Texas

THOMAS H. INCE OFFERS TRANS-PACIFIC FLIGHT PRIZE

THE Aero Club of America has sanctioned the contest for the $50,000 prize offered for the first trans-Pacific flight by Thomas H. Ince. The rules and regulations for the contest are as follows:

"Thomas H. Ince offers the sum of $50,000 to the aviator who shall first complete an aerial voyage across the Pacific Ocean in a heavier-than-air machine, mechanically propelled, of any size and type. Said flight may be attempted from either side of the ocean, but if westward the starting place must be from the Thomas H. Ince Aviation Field at Venice, Cal., or the Thomas H. Ince Hydroaeroplane Station at Venice, Cal., and the finish must be on the mainland of the Japanese group of islands or the mainland of the Philippine group of islands or the continent of Asia; if eastward, the mainland of the Japanese group of islands or the mainland of the Philippine group of islands or the continent of Asia, and the finish must be on the mainland of the United States of America. The course of said flight must be confined to latitudes 49 degrees north, and 32 degrees, 33 minutes, north, of the United States of America, and latitudes 41 degrees, 35 minutes, 20 seconds, north, and 38 degrees, 45 minutes, south, of the Eastern Pacific.

Auspices

"The contest will be conducted by the Aero Club of America, through its official affiliation and representative, the Pacific Aero Club, and shall comply with the rules and regulations of the Federation Aeronautique Internationals.

Time Limit

"The contest shall be confined between the months of September, 1919, and February, 1920, inclusive, and contestants must complete the trans-Pacific flight within two hundred and eighty-eight (288) hours from the time of starting.

Awards

"In the event that no contestant shall successfully complete a trans-Pacific flight, for which the sum of fifty thousand ($50,000) dollars is offered, the contestant starting from the Thomas H. Ince Aviation field at Venice, Cal., or the Thomas H. Ince Hydroaeroplane Station at Venice, Cal., who shall have reached the Hawaiian Islands in the shortest length of time, shall be awarded the sum of ten thousand ($10,000) dollars; and in the event that no contestant shall complete a flight to the Hawaiian Islands, the contestant starting from the two above-mentioned places who shall fly the furthest in the direction of the Hawaiian Islands shall be awarded the sum of five thousand $5,000) dollars.

Qualification of Contestants

"The contest is open to persons of any nationality holding an aviator's pilot license issued by any accredited aero club affiliated with the Federation Aeronautique Internationale, or to persons who have been so rated by any military or naval establishment.

Entries

"The entry form, which must be accompanied by the entrance fee of $500, must be sent to the secretary of the Pacific Aero Club, Monadnock Building, San Francisco, Cal., at least fourteen days before the entrant makes his first attempt. No entrance fee will be required of any military or naval contestant. Foreign entries will make application to the clubs in their respective countries which are affiliated with the Federation Aeronautique Internationale.

Thomas H. Ince signing his personal check for $50,000, which he presented to the City of Venice, Cal., with which to pay the first aviator to cross the Pacific

"No part of the entrance fees are to be received by Thomas H. Ince. All such entrance fees will be applied toward payment of the expenses of the Pacific Aero Club in conducting the contest. Any balance not so expended will be refunded to the contestants pro rata.

Starts

"The start of contestants may be made from land or water, but in the latter case the contestants must cross the coast line at the beginning and end of flight. The time will be taken from the moment of leaving the land or crossing the coast line. Each contestant shall advise the Pacific Aero Club of the proposed date and time of his start, as all starts must be made under the supervision of an official or officials of the above-mentioned club.

Air Mileage

"Ninety-five per cent of the mileage traveled from starting point to finish must be accomplished in the air. Barographs, officially sealed, shall be attached to each aircraft before starting, and opened only in the presence of an accredited representative of the Pacific Aero Club. The recordings of these barographs shall determine the air mileage actually traveled.

Towing

"Towing is not prohibited.

"Stops and landings, either on the water or at any point en route, may be made by the contestants.

Identification of Aircraft

"Only one aircraft may be used for each attempt. It may be repaired en route. Each aircraft will be so marked before starting that it can be identified on reaching its destination.

Finish

"The finish may be made on land or water. The time will be taken at the moment of crossing the coast line in flight or touching land. Each contestant shall advise the Pacific Aero Club of his proposed destination and alighting place.

General

"(1) A contestant by entering thereby agrees that he is bound by the regulations herein contained or to be hereafter issued in connection with this contest.

"(2) The interpretation of these regulations or of any to be hereafter issued will rest entirely with the official committee of the Pacific Aero Club.

"(3) The contestant shall be solely responsible to the officials for the due observance of these regulations, and shall be the person with whom the officials will deal in respect thereof, or of any question out of this contest.

"(4) A contestant by entering waives any right of action against the Federation Aeronautique Internationale, the Aero Club of America, the Pacific Aero Club

FOREIGN NEWS

Noted Swiss Flier Killed

Oscar Bider, reputed the leading Swiss flier, was killed July 5 in a fall from a height of 3,000 feet near Zurich. Bider, who was the chief pilot of the Swiss army, was performing acrobatic stunts preparatory to a public exhibition. Oscar Bider was one of the first to fly across the Bernese Alps, having made several trips over the mountains in 1913. In the same year he flew across the Pyrenees from Pau, France, to Madrid.

A New British Rigid Airship

According to notices appearing in the daily press, the new rigid airship, R-39, now under construction at the works of Sir W. G. Armstrong Whitworth & Co., Ltd., Barlow, near Selby, Yorkshire, is to have an overall length of 685 feet, a maximum diameter of 85 feet and a gross lift of 80 tons. The power plant is said to consist of six engines of 350 horsepower each, and it is hoped that the speed attained will be over 70 miles per hour.

A 900 H.P. Sunbeam Engine

According to the *Daily Express* of May 11th, the Sunbeam Motor Car Co., Ltd., have just made preliminary tests of a new 12-cylinder "Vee" type engine of 900 normal b.h.p.

No other information is as yet available.

Aerial Progress in Australia

Mr. R. Lloyd's aerial survey party have arrived at Burketown, Queensland, after a very rough journey of 2,550 miles across country from Sydney to the Gulf of Carpentaria. They located aerial landing stations and relay and fuel depots on their route, each 390 miles apart, so that a chain of landing stations from Sydney through Queensland and along the Gulf route is now completely charted except for the Darwin site, which will be chosen at the end of the survey party's journey. There is to be a station at Borooloola, in the Northern Territory. An alternative interior route will be surveyed from Camooweal to the Catherine River by way of the Newcastle waters and across the heart of the Northern Territory.

Civil Aviation in Brazil

According to *Auto Propulsao*, of May 15th, the Brazilian Minister of Communications has authorized the publication of official instructions relative to interstate and foreign aerial transport service in Brazil.

The principal points of the regulations are summed up as follows:

The network of aerial communications will cover all the State capitals, but concessionaires may, with the permission of the Government, extend their services to other cities if it is found to be desirable on commercial or industrial grounds.

Two years will be allowed to concessionaires for organizing connections between capitals.

Concessions carry no monopoly of any kind; they will cover aerial transport of passengers, mails and small parcels as soon as it is considered sufficiently safe.

The obligatory number of journeys, fares and rates are to be fixed by schedules agreed upon with the Government.

No letter or publication may be carried without proper postage stamps.

No passenger or goods service is to be started without previous license of the Federal Government, which will regulate the conditions of the service under its own direct inspection and supervision.

Concessionaires will be obliged to admit to their workshops and upon their machines cadets of the National Flying Services.

Concessions will be granted for a period of ten years, and concessionaires must undertake to fulfill any obligations ordered by the Government in the future, without any claim to indemnity, in so far as relates to questions involving aerial dominion or the national security.

After two years the Government may order that all commanding officers, pilots and crews of aircraft engaged in such services shall be Brazilian citizens and that the aircraft employed shall be registered as Brazilian at the Inspection Department of the Marine and River Transport Department of the Ministry of Communications.

Aerial Pleasure Service in England

It is understood that arrangements have now been completed for an aerial pleasure service to be run at Brighton during the summer. Land machines and seaplanes will be used, and permission has been granted for the machines to use "The Ladies' Mile" at the north end of the town as a landing ground. A rental of £15 per season will be charged for this ground, and each seaplane will be charged 10s. per week.

An Interesting Career

The fame of the Rolls-Royce engine, to which the trans-Atlantic flight has added further laurels, makes interesting the identity of the man responsible for its creation. Yet of all the men whom the motor movement has pushed into the limelight of prominence, it is doubtful if there be one whose personality is so unknown as Mr. F. Henry Royce, M.I.M.E., M.I.E.E., etc., to whose fertility of invention and creative genius the Rolls-Royce owes its unrivalled position in the world to-day.

Born in 1863, the son of a farmer in South Rutlandshire, he was obliged to begin work at an early age owing to the death of his father, who for a few years previous to his death had been the technical expert for a steam flour milling concern. The insight into mechanics afforded by his father's occupation gave young Royce his first incentive to engineering, which was subsequently to make his name world-famous. A few years' apprenticeship at the G.N.R. locomotive works at Peterborough, during which time he devoted himself to the study of mechanical science at the City Guild Technical College under Professors Ayrton and Perry, laid the foundation of his acquaintance with practical mechanics, which has since served him and the motor movement in such good stead.

In his eighteenth year he obtained employment at Leeds as an engineering fitter, and worked long hours building and testing machines for the Royal Italian Arsenal, then being built. Before his twentieth birthday he had removed to London, and from the parent company was sent to Liverpool to be chief electrical engineer to the Lancashire Maxim and Weston Company in that city.

The firm of Royce, Limited, was started in 1884, when its founder was of age, in conjunction with Mr. Ernest A. Claremont, of Manchester. From very small beginnings, making arc lamps and dynamos, the firm subsequently branches out into electromotors and electrically driven cranes, in connection with which the name of Royce is famous to this day. The large electrically driven Goliath cranes are perhaps the best known of Mr. Royce's productions in this line.

It was not until 1903 that he turned his attention to the motor industry, on the invitation of the late the Hon. C. S. Rolls, the outcome being the formation of the firm of Rolls-Royce. From the little 10-horse-power car which first carried the colors of Rolls-Royce to the enormous Vickers "Vimy" aeroplane, propelled by two Rolls-Royce "Eagle" engines across the Atlantic, it has been the brain of Mr. F. H. Royce which has worked out every minute detail of development and perfection which pertains to the name of Rolls-Royce.

Nor is this renown a matter of appropriating the work of subordinates, as too frequently happens in the case of much advertised geniuses. Mr. Royce is a man who can and does handle any tool like a craftsman, but he is, moreover, equally fertile in designing improvements in tools, as every mechanic in the great works at Derby can bear witness. But more valuable still than personal handicraft is the faculty he possesses of selecting the best men to carry out his designs, to which is largely due the super-excellence of every minute detail of the Rolls-Royce engine and car.

In South Africa

A commercial aviation company, with an initial capital of £100,000, has been started at Johannesburg. Services will be run at the end of the year between Johannesburg, Pretoria, Maritzburg, and Durban.

The largest machine will carry 24 passengers and about 500 pounds weight of parcels. The fare from Johannesburg to Durban, as far as can be estimated at present, will be about £10, and the parcel rate 1s. per lb. As soon as regular services are in operation the company will tender for the carriage of mails.

The following are comparisons of the times taken respectively by train and estimated to be taken by aeroplane between various towns.

	By Train.	By Air.
Capetown to Pretoria, 1,001 miles.....	47¾ hr.	9 hr.
Durban to Pretoria, 519 miles.....	24 hr.	4 hr.
Pretoria to Johannesburg, 39 miles.....	80 min.	30 min.
Bloemfontein to Johannesburg, 290 miles..	11½ hr.	3½ hr.

A flying school is about to be opened in Johannesburg, the course lasting about six weeks, and including 20 hours' solo flying, ground instruction, care and maintenance of aircraft, map-reading, cross-country flying, and aerial navigation.

In Brazil

The Brazilian Minister of Transport has instructed the Department of Maritime and River Transport to study the conditions of aerial transport in order to draw up regulations regarding aerial navigation in Brazil.

It is reported that an Italian-Brazilian company has been formed for the purpose of establishing aerial communication in Brazil, and have entered into negotiations for concessions to that end from the Ministry of Transport.

It is proposed to commence with a service between Rio Grande and Porto Alegre.

The machines to be used will be Caproni seaplanes—"much less perilous than aeroplanes," as the Brazilian paper puts it.

Concessions have been granted by the Brazilian Government to: Senors Joao Lexeira Soares and Antonio Rossi to institute aerial transport services between the principal cities of Brazil. (Decree No. 13,244, October 23, 1918.)

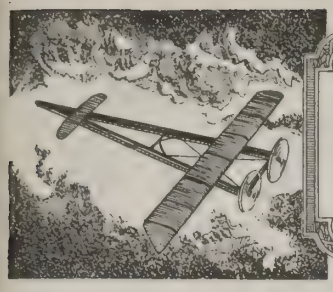
Sonors Joao Baptista dos Santos and Augusto de Aranjo Goes to use aerial means of transport—including seaplanes for the transport of passengers and goods in Brazil.

New Swedish Aerodrome

It would appear that Sweden is really out to develop commercial aviation. A message from Gothenburg states that negotiations are being carried on for the purchase of a number of farms on the island of Hisingen, opposite Gothenburg, with the objeet of establishing a flying port.

To Check Forest Fires

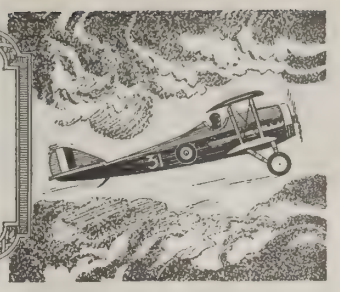
Definite steps are now being taken in the direction of organizing patrol over Canadian forests. A seaplane has arrived in the St. Maurice valley from Halifax, while a second is due to arrive shortly. Arrangements are being made by the St. Maurice Valley Forest Protective Association to provide centres throughout the forest areas controlled by them with constant patrols of aeroplanes so as to signal immediately a forest fire is discovered to wireless stations and secure prompt assistance. Active support is being given to this work by the Dominion Government, as it is believed that it will prove the best plan yet adopted for the prevention of forest fires.



Aircraft Insurance Profits to be Divided

London.—The Aviation Insurance Association is stated to have decided to share its profits with its policy holders. It appears that some owners of aircraft think that the rates charged for accidental damage at present are too high, but if this should be proved to be so, the objection will be removed by the participating policy whereby excessive profit (if any) will be returned to the insured.

By this scheme the insured will participate in 50 per cent. of the profit derived from aircraft damage insurance business. The whole of the premiums derived from participating aircraft business will be pooled, and the insured will, as soon as the underwriting accounts for the year have been closed, participate in the above proportion of the profits according to the amount of the premiums he has paid. In no case, however, will the amount payable under this scheme be more than 75 per cent. of the actual profit on the policy in question, and where a policy has made a loss to the underwriters, there will, of course, be no return made.



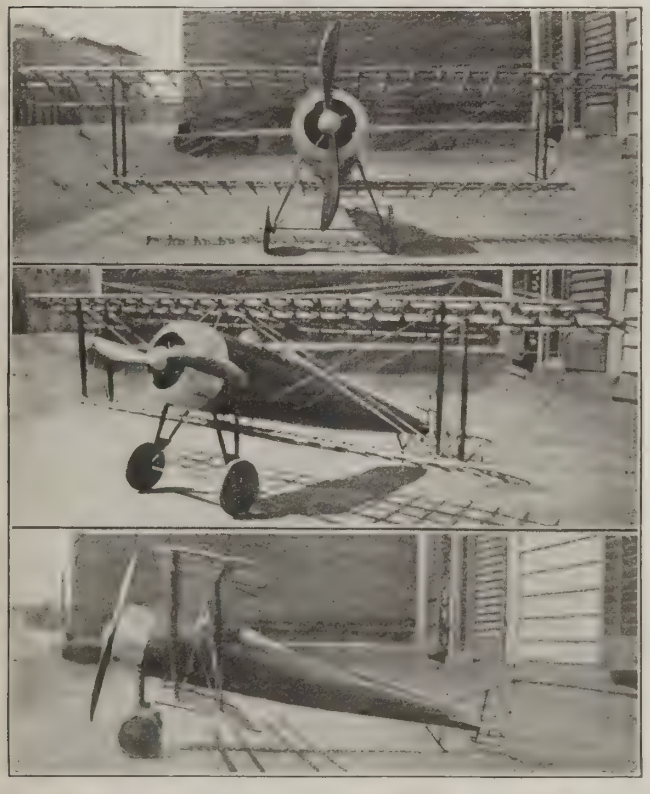
The accounts being made up only when the risks of the underwriting year have been closed, no provision is necessary for unexpired risk or for outstanding claims, and the amount of profit can be calculated therefore on a very simple basis.

The scheme is one which should appeal to owners of aircraft, who will be assured that should experience prove the rates quoted to be excessive, they will be corrected in this simple manner.

ELEMENTARY AERONAUTICS *and* MODEL NOTES

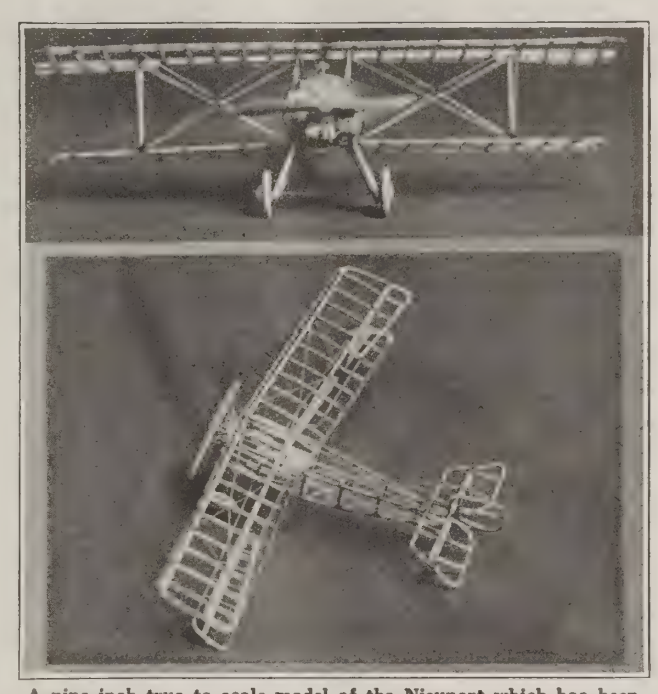
By John F. McMahon

Scale Models for the Aerial Age Cup



Many interesting photographs have been received at this office, and some of them are illustrated on this page. As it is impossible to reproduce pictures of all the machines at the present time, only those which show especial merit will be printed now, the others will be described when we have the available space. Those who have not as yet sent in their photographs have another week in which to do so, but July 21 will be the last day photographs will be accepted, as some of the model builders who were first to send in their designs are getting anxious to read the winner's name.

Since the prizes were shown on this page recently, many new entries with full descriptions have come into the office. Please write a full description of your model and send it in to the Model Editor with a clear photograph. Do it now in order to reach this office by next Monday morning at the latest.



Model of the Berckmans Speed Scout

The model shown at the left side of the page is of the Berckmans Speed Scout, which was described in AERIAL AGE some time ago. This machine performed very well in the hands of Mr. Bert Acosta at Central Park, L. I., making a speed of 115 M.P.H. with only an 80 H.P. Gnome engine. It was later flown at the Sheepshead Bay Speedway by Joe Stehlin, an American who was in the French Flying Corps, on his return to this country.

The builder of this machine, Mr. Harry Smalline, 227 Lewis Avenue, Brooklyn, N. Y., was also one of the Berckmans mechanics, and for that reason not a thing is missing from the model that is on the big machine. You will see that even the ribs are made exactly as a big aeroplane's ribs are made, and the turnbuckles are right and left as you will find on the big machine.

Scale model of the Berckmans Scout made by Harry Smalline of Brooklyn, N. Y.

A nine inch true to scale model of the Nieuport which has been whittled with no other tool but a jack knife

The general specifications are as follows:

Span, upper plane	5'-2"
Span, lower plane	4'-1"
Chord, both planes	8½"
Stagger	15°
Length overall	3'-8"
Weight	6 lbs.
Engine	A dummy model of the Gnome 80 H.P.

The fuselage is of the monocoque type, built up of 3-ply veneer with a fine tapered streamlined form. The laminations are 1/40 of an inch thick with coarse mesh fabric between to keep glue from shearing. A stick control is fitted for the ailerons (Nieuport type) and the elevator. A foot bar is installed for the rudder. The "I" beam main spars can be seen from the photograph. And in fact nothing has been left out which is on the original Berckmans Scout.

Model of the Nieuport Scout

Here is another interesting model from an educational standpoint, inasmuch as this model was made with a pocket knife by a lad from Lincoln, Nebraska. The model is made to scale and so well proportioned that the people of Nebraska think this boy will turn out to be a great aeroplane builder. The model is only nine inches across, but every part is constructed perfectly even to the wing curve. The motor is a dummy made up of a round piece of wood for the crankcase and smaller pieces of wood for the cylinders. The model is built up of spruce and bamboo. It caused such a sensation in Lincoln that Captain Horace B. Wild of the Flying Corps gave the model and its builder a five column write-up in one of the local papers. It was constructed by Master Willard Woods, 2311 South 14th Street, Lincoln, Nebraska. Master Woods is about to build a large machine and is backed by some influential people of his town.

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

R. F. C. Slang

(R. Stanley Edwards in *Flying*)

It was on the flying-ground.

"See the tripehound zooming ceilingwards yonder?" inquired the young pilot, those wings still thrilled him each time his eyes lighted on them. "That one there—way beyond the old eggbeater. Can't you see the one I mean? Hoicking toward the K. B. ahead of her? There! Right above that ground-louse. Got her? Well, she's skippered by Nicholson, the chap who yanked off that stunt in the tabloid. You've read about it, of course. Crashed by a coalbox he was—got his windstick plop and made him take a toss, all out. She flattened, however, and hoicked him into the sea unhurt."

The day old Quirk smiled feebly. He had understood about two words, but knew the other was being amiable.

"What happened," he asked, noncommittally.

"Oh, he was yanked out. But he had stark vertical breeze for months after," and the pilot strolled away, tired of doing the honors.

(In order to make possible the translation of this specimen of "Flyese," our British contemporary, *Flying*, has published the following list of aeronautic slang phrases, with which some of our airmen are no doubt familiar.)

Air Terms and Slang used by both R. N. A. S. and R. F. C.

Flyese	Meaning
Busses	Aircraft of all kinds.
Dope, Engine Juice	Petrol or other motor spirit.
To Zoom	To shoot up in a plane.
To Hoick up or down	To rise or descend quickly in a plane.
To Flatten Out	To bring the machine parallel with the ground before landing.
Archibald or Archie	Anti-aircraft guns, British or enemy.
Fritz or Coalbox	German shell.
Skipper	Pilot.
Tripehound or Tripe	Triplane.
Flaming Onions	German rockets or projectiles used for anti-aircraft purposes and sent up in strings.
Gadget	Accessory, fitting, anything difficult to rememebr or define.
Super-gadget	The latest thing in fittings.
Joy Stick	Control lever.
Wind Stick	Propeller.
To get "Vertical breeze or "Vertical gust"	To "get the wind up," to be scared, to have cold feet, to have nerves after a spill.
Spin	Twisting flight.
A Flip	A journey in the air.
K.B.	A sausage or kite balloon.
To take a Toss	To have a spill.
Stunt	Trick, dodge, fancy-flying, intricate airmancraft. Used for everything in the air and on terra firma.
To Crash	To fall. To come down with a rush.
Ceiling or Roof	The greatest height at which it is possible to fly.
Cold Feet	See "Vertical breeze."
To Yank	To pull.
For Bombs to *"Straddle"*	To drop on each side of the object aimed at.
A Tabloid	A single-seated Sopwith scout biplane.
All Out	Full speed ahead.
To Snooker or Stymy	To "make a bloomer" or to "do a man in."
To "Get his Wings"	To graduate as a pilot.
To "Get his Ticket"	To get his Aero Club pilot's certificate.
Plop	Whack.
Ferry Pilot	A pilot who takes planes from one aerodrome to another or across seas.
Stunt Pilot	A clever trick-pilot.
Unstrafed	Unbeaten, unpunished.
To Peter Out	For an engine to stop.
To Miss a Prop	To lose the prop for the propeller, to stop dead.
Rupert	Kite balloon.
Traveling Circuses	Specialized German fighting squadrons.
A Noah-Cæsar Bus	An antiquated machine.
To Blaze the Trail	To strike out in a certain direction.
On the Silvery Side	Above the clouds.
Dromewards	Homewards.
Fokker	An obsolete German.
Stark	Absolute.
To Stall	To lose one's flying speed when control is likely to be lost.
Tailslide	To come down backwards in a plane.
Spiral Dive	To come down corkscrew-wise.
Fraternity Jacket	Airman's tunic.
Rumpety	School plane.
Egg-beater	A twin propeller Wright-type machine.

Obstruction—From "Flight"

(To be continued)

Flexibility and versatility, resulting from combined stability and strength, commend Boeing Seaplanes to professional pilots and to sportsmen of the air. Ability to stand up under the most gruelling tests and day-in, day-out service, the result of perfected materials and refined craftsmanship, assure safety to the most daring. The greatest spruce-producing country in the world, surrounding the place of Boeing manufacture, gives its best wood to Boeing aircraft. Boeing Seaplanes combine symmetric and assymetric stability to a degree never hitherto attained. May we address you a personal letter?

Lieutenant Fetters Makes First Flight Across the Cascade Mountains

The War Department was notified July 5 that Lieutenant Jay M. Fetters, flying from Portland, Ore., to points in Oregon, Washington, and Idaho, where the aeroplane had never been seen before, had reached The Dalles on the return trip, having covered 1,457 miles in 1,130 minutes. He was the first aviator to cross the Cascade Mountains, making twenty-five landings.

Captain Howell H. Smith, in a De Haviland Bluebird plane, on his flight from San Francisco to Ogden, Utah, averaged for the distance of 693 miles a speed of 133 4/5 miles an hour, and on the return trip to San Francisco he covered a distance of 655 miles at an average speed of 130 7/10 miles per hour. He flew at an altitude of 9,000 feet.

Dodd Commands Langley

Colonel Townsend F. Dodd, Military Aviator, took command of Langley Field, Va., post, Colonel Wm. Hensley, Jr., being granted leave of absence to sail on the Dirigible R-34. Colonel Hensley is a Balloon Observer, dirigible pilot, and heavier-than-air J. M. A.

Air Service Leads

Men of the Air Service in the Army received more Distinguished Service Crosses than those of any other branch of the service, with, of course, the exception of the infantry. Official announcement made by General March, Chief of the General Staff, shows that 3,819 crosses were awarded to Air Service men. The Medical Corps came third, and then, in order, the Artillery, the Engineer Corps and the Signal Corps.

Curtiss Banquet to NC Crews

The grand ballroom at the Hotel Commodore was fitted up on the evening of July 10 to the last detail as the cabin of an NC flying boat, in which was served a dinner for the officers and crews of the NC-4, NC-3 and NC-1. Other guests were military and scientific experts who helped in the development of the first machine to fly across the Atlantic.

Glenn H. Curtiss, for whose name the "C" in NC stands, was the host.

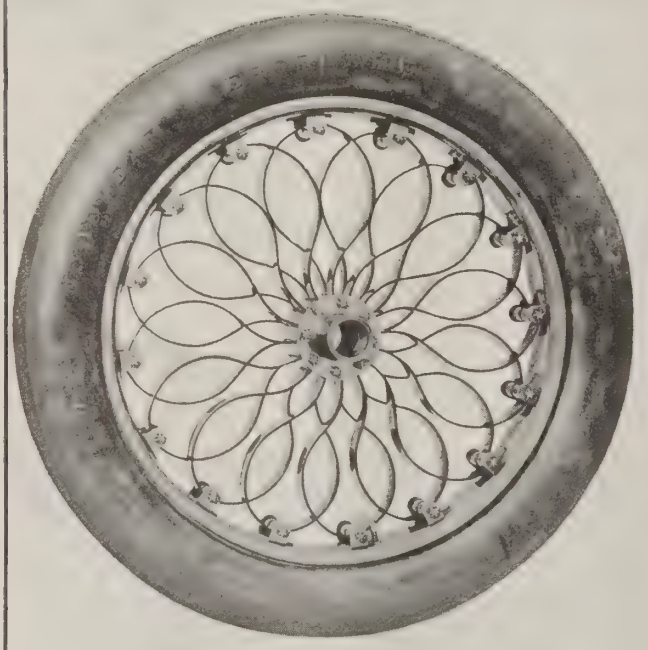
The "cabin" in which the diners seated themselves was that of the "NC-9" bound from New York to Plymouth, England, in May, 1920. Along the sides were ports through which could be caught glimpses of a swift panorama of cloudland, through which occasionally drove other flying boats or huge dirigibles. At intervals the sea, remotely rippled by the gale on which the "NC-9" drove along, appeared through gaps in the clouds.

There was even a wireless, operatod by Jack Binns, who sent the "messages" received to the guests for whom they were intended by a feminine Jack tar. There was nothing feminine, however, about the bo's'n whose preliminary calls: "All hands stand by to get under way!" and the like, followed by the officers' call on a bugle, gave an aeronautical air of expectancy and departure to the ballroom.

Quite appropriately, the fish was served just as the "NC-9" reached "midocean" and was gathering in wireless gossip from both hemispheres and the upper and nether world. The diners drank a silent toast in ice water when Brigadier General Charlton, British air attaché, received a "message" from General Maitland aboard the R-34 making an appointment for a meeting at the Savoy bar.

Another "message" from the R-34 warned the NC-9 to keep to its own side of the road and not go cluttering up other folks' sky.

"For goodness' sake," scolded the big dirigible, "keep clear of our track and follow the road laid down by the Bureau of Navigation!"



There was a masque showing the development of navigation from the time of Columbus to that of the "nancies" and souvenirs in the shape of books and medals were given to each guest in commemoration of the first transatlantic flight. In addition, each member of the three crews received a gold watch, engraved upon the back with an inscription concerning the flight whose dial guard formed the letters "NC."

Irvin S. Cobb was toastmaster. Among the others present were Lieutenant Comamnder A. C. Read, commander of the NC-4; Commander John H. Towers, of the NC-3, flight-commander; Lieutenant Commander P. N. L. Bellinger, of the NC-1; Chief Special Mechanic E. Harry Howard, engineer of the NC-4, who was unable to make the flight because of an accident just before the start, which cost him his hand as well as the trip; Admiral James H. Glennon, Captain Powers Symington, Noble E. Irwin, Dr. A. F. Zahm, C. M. Manley, Frank H. Russell, J. N. Willys, Captain Norman P. Hall and Commander R. W. Cabaniss; Admiral D. W. Taylor, Commander G. C. Westervelt and Commander Jerome Hunsacker, all of the Naval Bureau of Construction and Repairs, and W. L. Gilmore, Commander H. C. Richardson and Henry Klelckler, who were associated with the members of the bureau in designing the NC-4.

Pioneers in

Aviation Insurance of all kinds in the U. S.

We write all lines of insurance on AEROPLANES, SEAPLANES, DIRIGIBLES, KITES, FREE BALLOONS, etc.

Compensation, public liability, property damage, accident and life insurance on passengers and pilots. Fire, theft, burglary and collision.

No matter what you want to insure, come to us.

We make a specialty of AUTOMOBILE policies.

(*Continued from page* 888)

national advisory committees were constituted to study these subjects as follows:

1. Mechanical Tests. Definitions of terms used in the heat treatment and testing of steel.
2. Chemical Analysis. Methods of analysis of metals for use as a reference.
3. Tolerance on Bars. (For sizes of bars in both metric and British measure.)
4. Magnetos. Interchangeability of complete magnetos.
5. Sparking Plugs. Interchangeability.
6. Propeller Hubs. Interchangeability of propeller and hub.
7. Ball Bearings. Interchangeability and sizes.
8. Axles, Hubs, Rims, Tires. Interchangeability and sizes.
9. Electrical. To consider what electrical apparatus should be interchangeable.
10. Steel Tubes. Interchangeability and sizes.
11. Tests on Wood. To obtain agreement on methods of tests.

These advisory committees will meet from time to time in order to prepare proposals which, after having been referred to and agreed upon by the national committees, will be submitted to a plenary meeting of the Commission for adoption and issue as International Aircraft Standards.

Note in Regard to Formation of National Committees

In most countries there now exists, or is in process of formation, an Engineering Standards Association, the object being to centralize, as far as possible, in one authoritative organization the standardization of engineering and allied materials. Such bodies are generally divided into various Sections dealing with the different branches of the engineering and allied industries. For instance, in France, Great Britain and the United States, the Committee of the Standardizing Authority for the country, controlling the aircraft section has been officially nominated as the National Committee of the International Aircraft Standards Commission.

In the case of Great Britain, the British Engineering Standards Association has 24 Sectional Committees controlling the national standards of all kinds of engineering and allied material including an Aircraft Section. The Aircraft Sectional Committee has some 60 Sub-Committees and has in operation over 200 Specifications for aircraft materials, prepared and kept up to date by these Sub-Committees. This Section being now the British National Committee of the International Aircraft Standards Commission, it has therefore at its disposal the work of all these Committees as well as the work of every other Sectional Committee interested. This plan is being adopted in America and France and seems likely to be universally adopted.

(*Continued from page* 899)

or Thomas H. Ince for any damages sustained by him in consequence of any act or omission on the part of the officials of any of the above-mentional clubs or Thomas H. Ince or their representatives or servants or any fellow contestant.

"(5) The aircraft used shall be at all times at the risk in all respect of the contestant, who shall be deemed by entry to agree to waive all claim for injury either to himself or his passengers or his aircraft, or his employees or workmen, and to assume all liability for damage to third parties or their property, and to indemnify the above-mentioned clubs and Thomas H. Ince in respect thereof."

Personal Pars

William Knight, formerly assistant mechanical engineer of the Crocker-Wheeler Company, Ampere, N. J., and during the war a first lieutenant in the Air Service, U. S. A., has recently been appointed technical assistant to the National Advisory Committee for Aeronautics in Europe, with headquarters in Paris, France.

H. R. Trotter, formerly chief engineer of the S K F Ball Bearing Company, has been appointed chief engineer of the S K F Industries, Inc., New York. The S K F Industries, Inc., has recently been organized to supervise the sales and engineering activities of the Hess-Bright Manufacturing Company, the Atlas Ball Company, the S K F Engineering Laboratories and the S K F Ball Bearing Company.

G. Edward Barnhart has resigned as chief engineer in charge of the production of Handley Page planes at the plant of the Standard Aircraft Corporation, Elizabeth, N. J., and has accepted the position of mechanical engineer in the experimental engineering department of the B. F. Goodrich Co., Akron, Ohio.

Edward L. Jones, who has been associated with the sales departments of the Remy Electric Co. and Standard Parts Co., has been appointed special factory representative of the Perfection Heater & Mfg. Co., Cleveland, Ohio.

O. F. Kropf, secretary-treasurer, Findeisen & Kropf Mfg. Co., Chicago, Ill., has been elected president of the recently formed Beneke-Kropf Mfg. Co. The new organization has succeeded the Findeisen & Kropf Mfg. Co. and will continue the manufacture of the Rayfield carbureter.

VOL. IX NEW YORK, JULY 28, 1919 NO. 20

LARGE DEMAND FOR AEROPLANES

THERE are over 500 people who have purchased or ordered an aeroplane in the United States during the past three months, and not less than 500 more are anxious to place their orders but cannot do so because the manufacturers are rushed with orders and cannot promise deliveries.

This is one of the important facts ascertained by the committee in charge of organizing the Pioneer Aeroplane Tours.

The Curtiss Company alone has orders for over three hundred aeroplanes, and is so rushed with prospective orders that it has found it necessary to put on two shifts in its factories at Garden City and Buffalo.

Over 130 orders have been received by the Curtiss Company for the pleasure type biplane called the "Oriole," because it is painted like an oriole. The Curtiss Company already has more orders than it can fill this summer for pleasure type seaplanes of the type called the "Seagull." The Curtiss factories are turning out an average of one a day of both the "Oriole" and "Seagull" types. The orders for planes range from the one-passenger type to the ten-passenger type, with a few orders for larger machines. The passenger carrying business is also flourishing and there is a large demand for aerial passenger carrying transportation lines. Every day people wait in line for an opportunity to take a flight in a flying boat down the Boardwalk toward the Inlet, where there are three flying boats in operation, carrying passengers from morning till night. It is a common sight to see a man or woman in a hotel talking wildly and waving their hands to illustrate the motions gone through in making an aeroplane flight with one of the aviators at the Atlantic City Airport.

It is unfortunate for the aeronautic movement that the manufacturers are not in a position to make the necessary deliveries of aeroplanes. Not less than 2,000 pleasure machines could be sold immediately if the manufacturers were in a position to make deliveries.

Fortunately for the aeronautic movement, the several thousand planes which the Government has sold and other planes which the Army and Navy may sell in the near future, will soon be available. They will be available for the Tours, which promise to start with a surprisingly large number of entries.

DEMORALIZING THE ARMY AIR SERVICE

UNLESS some sudden readjustment occurs the Army Air Service faces absolute demoralization, and all of the upbuilding work of the past two years, and the money expended, will have been for nothing. The New York *Times* discusses the situation as follows:

"The Air Service of the army faces demoralization as a result of orders issued by Secretary Baker, through the Adjutant General of the army, calling for the discharge of all temporary officers in the army by September 30. Secretary Baker and General March found themselves confronted, as a result of the slashes made by the Republican Congress, in the estimates for the support of the army, to order the discharge of all emergency appointment officers on or before September 30. The result will not only rob the service of some of its best fliers who entered from civilian life, but also force the abandonment of important army aviation projects.

"The Army Appropriation act carries a total of $25,000,000 only for army aviation. Men in charge of plans for army aviation development asserted that the army plans called for a minimum of $55,000,000 for the current fiscal year, or a maximum of $75,000,0000.

"With the discharge of all temporary officers by September 30 the army aviation stations in Hawaii and Panama will have to be abandoned, as well as the proposed Philippine aviation project, as there will be scarcely enough regular army officers to maintain even two squadrons on the Mexican border. It was asserted by officers of the Air Service that as a result of the situation now staring it in the face, no provision can be made for properly taking care of the millions of dollars' worth of aviation property at Government fields and in storage ports, that it will be impossible for the army to maintain a proper system of aviation coast defense, that it will not have sufficient fliers left to properly train personnel, that it will be without a proper administrative or executive force, and will be without any lighter-than-air facilities for more than one company.

"Men prominently identified with the army and interested in aviation regard this condition of affairs as being nothing short of deplorable. It is estimated that it cost the Government more than $10,000 a man to train its fliers. Ten fliers who entered the army from civil life for the period of the war have already signed contracts to go with private companies at approximately $100 a week to fly and do stunts at State fairs and in other kinds of exhibitions. These were lieutenants who were willing to remain in the army air service at $1,700 a year.

"On July 12 the Army Air Service consisted of 4,851 officers, including the Director of the Air Service; 417 officers awaiting discharge, and 369 on detached service. On the same date it comprised 14,413 enlisted men. There are now 1,319 overseas officers, rated as follows: Six hundred and six fliers, 678 nonfliers, 36 balloonists, and 3,859 enlisted men. The regular army enlisted men now in service number 7,365, but there are only 222 regular army officers in he Air Service. The rank and status of these regular army officers are:

	Fliers.	Nonfliers.
Major Generals	..	2
Brigadier Generals	2	..
Colonels	17	19
Lieutenant Colonels	50	21
Majors	66	21

Captains	8	6
First Lieutenants	6	4
Second Lieutenants	..	..
Totals	149	73

"This total includes thirteen who are balloonists and six who are observers. The officers now available in the United States are:

Fliers	1,269
Non-fliers	1,378
Balloonists	99
Total	2,746

"The great bulk of these, however, are temporary officers, who will be discharged from the service before September 30. The 222 officers of the regular establishment to be retained are not enough for three squadrons, exclusive of officers detailed for training, coast defense, and insular possessions. Projects having the approval of the army as of July 12, which will of necessity, it is asserted, have to be abandoned if the present orders for discharge of all temporary officers stand, are:

"Philippine project calling for four observation squadrons—Each squadron of this project called for a war strength of 45 officers, of which 41 would be fliers; total required, 164 fliers and 16 non-fliers.

"The Hawaiian project—One squadron already stationed there, two more authorized; total required, 123 fliers and 12 non-fliers.

"The Panama Project—One squadron, already stationed there, two more authorized; total required, 123 fliers and 12 non-fliers.

"The Border Patrol—Two squadrons operating, four more authorized; total required 246 fliers and 24 non-fliers.

"These projects alone required 656 fliers and 64 non-fliers.

"Forty-two balloon companies also were authorized and contemplated in the army's plans. These called for eight officers for each company, of which five were to be observers. The total number of officers required for approved projects was: Heavier-than-air, 656 fliers, 64 non-fliers; lighter-than-air, 210 fliers, 126 non-fliers. Total required, 866 fliers, 190 non-fliers.

"To meet this there is at present a regular army strength of 222 officers, consisting of 130 heavier-than-air pilots, 18 balloon pilots, 6 observers, 73 non-fliers.

"If existing orders are carried out the shortage on September 30 will be: Heavier-than-air pilots, 526; lighter-than-air pilots, 197; non-fliers, both branches, 117. Total, 840.

"This is the situation that has created demoralization in the Air Service of the army."

AIR DEPARTMENT TO BE URGED

SECRETARY OF WAR BAKER will be strongly urged soon to recommend to President Wilson and to Congress that control of aviation be taken from the army and navy and centered in a new department that may be headed by a cabinet member.

This statement was made to representatives of the New York press by members of the Aircraft Mission that returned on the Aquitania after an extensive tour of the aircraft factories in England. The mission comprised: Assistant Secretary of War Benedict Crowell; Colonel Blair, of the general staff of the army; Captain Mustin, U. S. N.; George W. Houston of the Wright-Martin Aircraft Corporation; C. W. Keyes, of the Curtiss Aeroplane and Motor Corporation, and S. S. Bradley, general manager of the Manufacturers' Aircraft Association.

"What we have seen abroad during the last several months has convinced us of the absolute necessity of a radical departure by America in aviation," said one of the group. "The War Department may be expected to recommend, and the Navy Department undoubtedly will concur, that aviation be made a branch of service entirely distinct and separate from the army and navy.

"The new Government Department of Aviation, to call it that for the moment, is to have control of all aviation in this country, including commercial enterprises in the air. In time of war the War Department can requisition the Aviation Department for so many planes and dirigibles and balloons, and the Navy Department can do likewise. In time of peace the new department can direct the development of American aviation, military, naval and commercial.

"If we are to catch up with the European nations, who have already far outstripped us in that field, and who are drawing further away every day, we must adopt this new program of control.

"Though the NC-4 made the first trans-Atlantic flight, the fact remains that it is Britain that has achieved the great successes of the air in recent months. And Britain's aviation program is almost spectacularly tremendous. France, too, is ambitious, and Italy is ahead of us.

"It is discouraging to those of us who have been in close contact with Europe's great program and brilliant air progress to learn that Congress is apathetic to our own aviation development. The thousands of resignations of aviators from our air service is a blow to our development in that line. There is no doubt whatever in the minds of those who have participated in this war, particularly those who have themselves been in America's air service, that the future, both in war and in peace, will find aviation a supreme factor in shaping the history of the nations. America, therefore, cannot afford to be a laggard if we are to retain our position among the great powers.

"There is also to be considered this important fact, that creation of a new department to take over entire control of all American aviation would do away with duplication of expenditures and result in a saving annually of hundreds of millions, perhaps billions, of dollars."

SPOKANE OFFERS EXCELLENT FACILITIES TO AVIATORS

NO city in the United States is more keenly alive to the possibilities of aviation than is Spokane. Already marked progress has been made, and well defined plans are afoot to place flying on a practical, commonsense basis.

The Spokane Flyers' Club has been launched with a membership of 30, all former officers in the army aviation service. Some of the members have flying records of 500 to 1,000 hours. It is believed the membership will shortly be 50. One aeroplane has been purchased, a Curtiss training machine, so that members may keep in training.

The personnel of the Spokane Flying Club, together with 60 other ranks from the army aviation service, form the first National Guard aviation squadron to offer its services to the Government. The organization is complete and ready to "carry on" as soon as Congress supplies the necessary machinery to incorporate aviation in the National Guard system.

A commercial aviation enterprise has been launched, and four machines have been ordered to start with. Spokane boasts a magnificent aviation field in Parkwater, on the outskirts of the city, where a two-way field of 500 acres offers landing grounds said to be unsurpassed in the United States. The Flyers' Club and the commercial enterprise will locate their hangars at Parkwater. The club hangar will include a practical work-shop where members will have an opportunity to test the ideas they have evolved as to improvements on present models. Several Spokane aviators have important innovations they are anxious to test out in practise.

Spokane is especially favored climatically for aviation. Fog is almost unknown, and the clarity of the air all the year round has been emphasized by experts in the moving picture trade.

This city is strongly recommended as a center for aeroplane body building. The choicest spruce is available in immense quantities, electrical power is plentiful and low in cost, and the city is exceptionally free from labor troubles, while the cost of living is comparatively very low. Any legitimate enterprise will have the strongest endorsement and support of local aviators.

The News of the Week

Aircraft Entertain Spectators at N. Y. Police Tourney

Sheepshead Bay, N. Y.—A large number of army planes, headed by a huge Handley-Paige bomber, participated in the events at the field days of the New York Police Force. Commander John H. Towers and Lieut. Commander Patrick N. Bellinger were taken to the field in army aeroplanes. Exhibtions of formation flying were given.

C. F. Kettering Covers 800 Miles in Fast Time

Dayton, Ohio.—Maintaining an average speed of 103.3 miles an hour, in spite of a direct head wind, all the way east from St. Louis, Charles F. Kettering, inventor, returned home today from a convention at Wichita, Kan. The De Haviland machine, piloted by Howard Rinehart, landed at South Field, Dayton, on July 19th, at 3:15 P. M., having covered 800 miles in seven hours and forty-five minutes.

Dirigible R-33 to Fly to India

The British dirigible R-33, sister ship of the R-34, which completed a round trip transatlantic voyage on Sunday, is being groomed for a flight to India. It is expected to leave some time this week.

The trip will be made by way of France, Switzerland, Italy and Egypt. A landing will be made in Rome and probably in Cairo. The flight is expected to occupy fifteen or twenty days at three-quarters speed.

Missionaries to Buy Curtiss Flying Boat for Use in Africa

A flying boat or an aeroplane may soon form a part of the equipment of modern missions in blackest Africa, according to a letter received yesterday by the Curtiss Aeroplane and Motor Corporation.

The letter was from the Congo Mission of the Disciples of Christ, the headquarters of which is at Coquilhatville, Belgian Congo.

"We are interested in the matter of the purchase of flying boats to replace wholly or in part the fleet of launches which we have been planning for service in communication between our various stations," the letter stated. "We have a large river steamer for transportation between stations which hydroplanes might supply. Our area is about 500 miles east and west and 200 miles north and south in extent. The whole area is covered well by an extensive system of waterways. In inland points landings might be made in small machines in the straight, smooth, central streets of the native towns, which in this section are usually clear of grass and other obstructions and are not less than 100 feet wide."

What the untamed congregations will think of the innovation is a matter of conjecture only.

Memorial to McConnell Unveiled

A statue to Lieut. James Rodgers McConnell, an American aviator killed in France in 1917, was unveiled at the University of Virginia. The statue, which is based on the legend of Daedalus, the Greek, was executed by Gutzon Borghem, and represents his interpretation of the "Spirit of Aviation."

Championship Balloon Race to Start From St. Louis

A balloon race for the United States championship will start from St. Louis October 1. The race will be conducted by the Missouri Aeronautical Society under the rules of the International Aeronautical Federation.

The first prize will be $500, the second $300 and the third $200.

Raynham Ordered Home, Abandons Flight Plan

Captain Frederick P. Raynham, the British aviator whose Martinsyde biplane was wrecked twice in two months spent in trying to start a trans-Atlantice flight, has received orders to abandon further attempts and return to England. Raynham and his navigator, Conrad H. Biddlecomb, directed the crating of their plane, and both expect to leave with it on the steamer Grampian. Their mechanics will return to England with them.

Aeroplane to Revolutionize Professional Baseball

New York, N. Y.—Commenting on the flight of a former professional baseball player from Colombey-les-Belles to Treves to umpire a game between two teams of the Seventh Division, John J. McGraw, the manager of the New York National League Baseball Club, predicted that aerial transport would revolutionize professional baseball.

"It certainly will make the job of constructing schedules an easy one," said Mr. McGraw. "At the present time trains and distance have to be considered most carefully, and in forming a circuit certain towns are automatically eliminated because they are too far away. It looks as if some day a team might be able to leave New York early enough in the morning to play in Pittsburgh, Chicago, or even St. Louis that afternoon.

"San Francisco might be able to become a member of one of the major leagues. San Antonio might play in the Connecticut League or Hartford in the Texas League. Twenty years from now we might be able to form a League of Nations, with London, Paris and Rome as members."

Three-Motored Monoplane to Attempt Trans-Atlantic Flight

Los Angeles, Cal.—George D. White, aeronautical engineer and head of the George D. White Company of Los Angeles, recently announced that he proposes in the near future to attempt to cross the Pacific Ocean in a 660 horse-power triple motored monoplane which he is now planning to build.

Relative to his route across the Pacific Mr. White said he had considered this from many angles and is convinced that a northern route by way of Alaska and Kamchatka would be the better under present conditions. With his machine Mr. White proposes to cover 7,000 miles, jumping off from Los Angeles, touching at San Francisco, Victoria, British Columbia, Sitka, Unalaska, Petro Pavlosk, Yokohama, and finally Shanghai, the end of the flight.

The northern route, it is estimated, will take three days, according to the plans from Los Angeles to Japan, a trip now requiring three weeks on the fastest boat.

Mr. White points out that it will be an independent flight and that his effort to be the first across the Pacific Ocean will not be so much an attempt to win the $50,000 prize offered by Thomas H. Ince as it will be to prove the reliability of the White monoplane.

To Build Dirigible at Philadelphia Yard

Philadelphia.—A dirigible similar to the British R-34, to be built at the navy yard here, will attempt within a year a flight to Europe, Commander Coburn, in charge of aircraft production for the navy at this

An experimental biplane constructed by the Farman Company. Note the method of mounting the two radial motors and the propeller shafting

point, announced. He also made public plans of the department to establish a landing field at Lakehurst, N. J., with hangars capable of housing balloons larger than any yet built.

Ships to Aid Flyers

Vessels will give longitude and latitude to trans-Atlantic flyers whenever occasion arises, if suggestions made by the National Advisory Committee for Aeronautics of the U. S. Shipping Board are carried out.

The Advisory Committee has recommended that all ships flying the American flag should be instructed to give all navigation assistance of this nature at all times in the future to trans-Atlantic flyers, and has asked the U. S. Shipping Board to convey the recommendations to all ocean-going vessels carrying the flag of the United States.

No Part in Aircraft Standards

As a result of action by Congress the plans for American participation in the International Aircraft Standards Commission Conference have been dropped. This conference, which was started during the war when delegates from all of the allied countries met in London and conferred on problems of aircraft standardization, is to be permanent, with a central office in London.

The provision for American participation was included in the army appropriation bill appropriating $1,000 toward the maintenance of the office and $50,000 for the expenses of delegates. As a result of the refusal of the House to agree to the provision as incorporated in the Senate army appropriation bill, this section of the bill was eliminated and participation of America in Standards Conferences ended.

An attempt will be made next year to secure appropriations for participation of American delegates for 1921.

Seventeen Fliers Entered in Toronto-New York Race

Seventeen entries and $10,000 in cash prizes and trophies are already assured for the aeroplane flights from here to New York which are to feature the Canadian National Exposition to be opened by the Prince of Wales on August 25, at Toronto.

So far all entries for the Toronto-New York race are from the United States, but twelve Canadian entries are expected before the exposition opens. Captured German Fokker planes, now in the possession of the Dominion Government, will be admitted to the contests it has been decided, provided their pilots hail from allied countries. There are twenty-two of these craft here now.

Airmen Dive Under Suspension Bridge at Niagara

Niagara Falls, N. Y.—L. H. Holmes, pilot, and S. Bonnick, aerial photographer, starting from Lake Side Aerodrome on the Hamilton Highway on July 11th made an aerial photography trip in the Niagara Falls region, taking pictures of Oakville, Burlington, Hamilton and St. Catherines, en route. After a short stay at Merritton for gasoline the Falls were reached at 4.30. Shooting over the Canadian Falls and through the spray, a perilous ride commenced. With engine full open, the machine shot down at a terrific speed under the Suspension Bridge and when attempting to rise again the air current was so great that the machine had to be piloted under the next two bridges, continuing down the river, narrowly missing the wires suspending the Aerial Car.

At the whirl pool the machine was still below the top of the gorge and a vertical bank had to be made at the right-angle bend in the river, narrowly missing the cliffs, and it was not until nearly at Brock's Monument that the machine rose just above the cliffs and flew into safety. Whilst Mr. Holmes was engaged in piloting the machine through the dangerous route, Mr. Bonnick was taking snap shots. Both Holmes and Bonnick were instructors in the Royal Air Force in Canada.

Civilian Aviators May Obtain Meterological Information From Washington

Washington, D. C.—Civilian aviators contemplating long cross-country flights in any part of the United States may now wire the metereological officer of the information group of the Air Service to find out what sort of weather they are likely to encounter, according to an announcement made by the Director of Air Service. This action is one of the first which implies recognition of the great part aviation is to play in commerce of the future.

"To assist aviators as far as possible to make their cross-country flights under favorable climatic conditions, subject to errors of a weather forecaster and without assuming any responsibility for accuracy, the meterological officer of the information group, Air Service, United States Army, will from the weather map reports and in consultation with the officials of the United States Weather Bureau attempt to forecast weather for flying in any part of the United States for thirty hours in advance of noon each day for the aviator making a request and stating points of intended flight," the announcement says.

"The result of this experiment may determine the value of an aerial meteorological service and warrant its organization as the cross-country flying increases and aircraft become more generally used for the transportation of passengers, mail and merchandise. Aviators making a flight following the prediction of the meteorological officer are requested to advise him as soon as possible as to the accuracy of the report."

Seaplane to Carry Manifests to Liners

A flying boat will carry mail to the trans-Atlantic liners when they are hours out of port, it was announced July 18 by the Post Office Department. The experiment in sea-aero mail service was decided upon by Otto Praeger, Second Assistant Postmaster General, after conference with David Lindsay of the International Mercantile Marine Company, which operates the White Star Line.

The first experiment will take place on August 9, when the Adriatic leaves New York on one of her regular trips. A mail pouch will be dropped on her deck several hours after she leaves her pier. The plan has been tried successfully by the United States Army and Navy in meeting troopships, but no commercial or postal service was ever used. The aero-marine service will save the ship many hours in getting away, for the necessary customs and tariff papers can be delivered by airplane to the ship at sea by the new method. It has not been decided yet whether a parachute will be atttached to the pouch.

Postmaster Patten says shipping companies regard the plan with considerable interest. Ships usually load until the last minute and then a manifest has to be prepared and filed with the Custom House as to what the vessel contains. The ship also has to have a copy of the manifest in order to dock at a European port. The time in copying and filing the manifest will be saved by the air service.

Mr. Praeger will be present when the first aero-marine flying boat takes off the Adriatic's papers and other special aeroplane trans-Atlantic mail.

Aeroplane to Be Used on Antarctic Trip

Two British aeroplane manufacturers have offered to give an aeroplane to J. L. Cope, leader of the British Imperial Antarctic Expedition, for a flight to the South Pole. It is declared to be Mr. Cope's intent to carry an aeroplane on board the exploring steamer Terra Nova, on which the expedition is to proceed until the vessel becomes fast from the ice.

Night Flight to Atlantic City

A Curtiss Sea Gull flying boat recently made the first night stop between New York and Atlantic City.

When the mechanics finished setting up the boat—it was almost eight o'clock, but, in order to get it to Earle L. Ovington, manager of the Curtiss Flying Station at Atlantic City, on time, Orton W. Hoover, one of the Curtiss pilots, left Port Washington hangars at 8.15. He started by moonlight against a heavy head wind, which made it necessary for him to land near Beach Haven for fuel.

Steering by means of a beach-fire, Pilot Hoover landed the boat safely upon the sand and, after procuring gasolene, he again made a take-off with the assistance of bathers, headed the Sea Gull out to sea, took the air and made Atlantic City at 11 o'clock.

The Sea Gull is the new three-passenger flying boat equipped with the Curtiss 150 horse-power motor.

Hoover, who is one of the most experienced pilots in the United States, took along as passengers Mr. and Mrs. C. R. Keys, of the Curtiss Engineering Corporation.

Admiral Kerr Discusses Flight

Admiral Mark Kerr, who was in charge of the Handley Page Atlantic flight expedition, accompanied by Mr. W. H. Workman, arrived at the Hotel Biltmore on July 15 from Parrsboro, Nova Scotia.

This is the second visit of the Admiral to this country, having been here in 1905, when he was in command of the H. M. S. Drake, of the second Cruiser Squadron of the British Navy, which visited these shores at that time, and was under command of the Prince Louis of Battenberg.

Admiral Kerr is the oldest aviator in the world, being 55 years of age, and he hopes to be flying when he is 70 to celebrate the twenty-first anniversary of the securing of his pilot certificate, which was issued to him six years ago, making him one of the pioneer aviators of Great Britain.

The Handley Page abandoned the Atlantic flight project in favor of a flight from Harbour Grace, Newfoundland, to Atlantic City on July 4th. An oil pipe breaking in one of the four engines caused a forced landing and they came down at Parrsboro, Nova Scotia, on a race course, and after making a perfect landing, came in contact with a concealed ditch which caused the machine to turn over on its nose just about the time the machine came to a standstill, which has made it necessary to repair the machine before it can resume its flight into America or on through Canada. When Admiral Kerr was asked about the flight he gave the following details:

"The flight to Parrsboro demonstrated several things, namely, the necessity for large aeroplanes, the necessity for multipled engine aeroplanes, the reliability of a machine equipped with several engines and the safety connected therewith.

"We left Harbour Grace at 6 P. M. on July 4th with a load of 29,000 pounds, the largest load ever carried by any type of aeroplane, which included the crew, consisting of Major Brackley, Major Gran, Mr. Wyatt, Engine Mechanic Arnold and Aeroplane Mechanic Elements. The machine was fitted with Marconi's directional wireless as well as a transmitting and receiving instrument. All of this equipment worked admirably. The course was laid for Sydney, which we passed at 10.15 P. M. The average speed being 83 miles per hour with an adverse wind against us. At 9 o'clock the crew had dinner in the cabin while the pilot at the wheel had his dinner brought to him, after which the off duty pilot had a few hours' sleep. At 11.30 I was piloting the machine and noticed that the starboard foremost engine was dropping revolutions and with the throttle wide open could only maintain 1,600 revolutions, and it was evident that something was wrong. Major Gran and Mechanic Arnold climbed out to the engine, but beyond finding a quantity of oil, they could not in the darkness ascertain the trouble. This feat on the part of Gran and Arnold was a very daring one and they deserve much credit for it. The engine continued to run at 1,600 revolutions until 2.05 A. M. in the morning, when one piston rod gave out and the cam rod broke, the engine cover passed through the fuselage together with several pieces of metal. The other three engines now had to do all the work and the throttles were open and the revolutions went up to 1,800 to 1,820. 'If they stick it out it will be the finest advertisement the Rolls Royce have ever had,' said one pilot to the other, and they did not only stick it out, but did so without a waver on the needles of the indicators, and as if they were only running on half a throttle and not full out all the time. It is safe to say that there is not another aeroplane engine in the world which could have gone through such a strain and test.

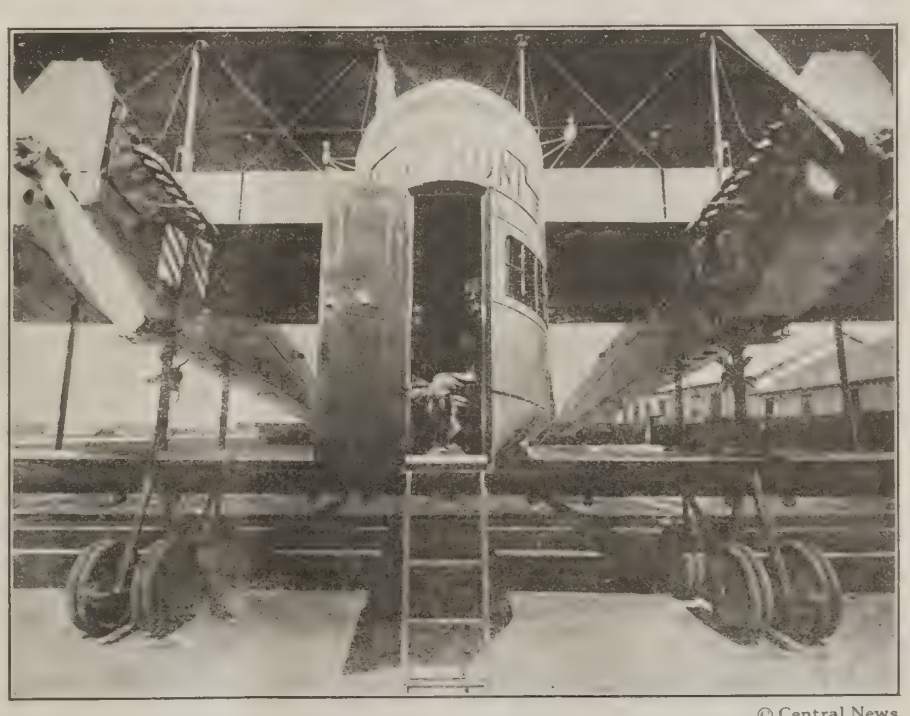
"These three engines kept the machine in the air with the weight of 26,000 pounds running practically for the whole time of three hours and fifty-five minutes until the landing at Parrsboro at 5.50 A. M., being in the air ten minutes short of twelve hours.

"The race course which we sighted from the air and about which we knew nothing, appeared to be a proper place to land as well as a safe place, and had it not been for the concealed ditch, a new engine could have been installed and the machine continue on its journey.

"In spite of the accident to the oil pipe terminating the voyage, there are some excellent lessons to be learned from this trip, and much encouragement for the development of commercial flying.

"First—It proves the value of multiple engine machines.

"Second—It shows what a Rolls Royce engine and a thoroughly well built aeroplane as the Handley Page can accomplish in the face of an accident, when thirteen tons are kept in the air for nearly four hours on three engines and might have kept up as long as there was gasoline to give the engines.



"Third—That wireless and directional wireless are of the greatest use in a machine large enough to carry them.

"Fourth—That comfort and sleep can be obtained in a Handley Page during a long flight.

"Fifth—In addition it is well to remember that in all the trans-Atlantic attempts, as well as this flight of twelve hours by a trans-Atlantic machine, not a single life has been lost or a bone broken. Given a good machine, good engines, good pilots, the risk in flying is very small. Neither is flying confined to any special age. I have been flying for over seven years and have been a pilot for five years and I will be 55 years old in September. One of the other pilots is close to 30 and the other under 25 years of age.

"I consider that there is a great future for commercial flying in America. The land of great distances, great trade and speed in and with which, if the aeroplane is used intelligently, will prove an enormous boom and an able assistance to commerce and travel over long distances and most especially in this, your wonderful country of America. Its capabilities are enormous and its future assured as long as its promoters remember two things—first its limitations and, second, reliability before all things."

Admiral Kerr is remaining in New York for a few days, after which he will return to Parrsboro to assist in repairing the machine, and he hopes to be able to fly it to Atlantic City in the very near future.

The car and landing gear of a Caproni passenger-carrying triplane

The AIRCRAFT TRADE REVIEW

Rolls Royce Director Arrives in U. S.

New York.—Claude Johnson, managing director of Rolls-Royce, Ltd., arrived in the United States recently from London for a conference with American representatives of the famous British motor corporation. He was not at liberty, he said, to discuss the company's American affairs.

Test Gasolene Substitute

Fifty automobiles climbed the steep Dock street hill in Yonkers after their tanks had been emptied of gasolene and filled with a substitute for it devised by Dr. Louis Clement. The demonstration was under the direction of the Society for the Advancement of American Inventors, Inc.

The principal ingredients of the substitute, which is known as "nuoline," are kerosene, naphtha and water. It can be made in 20 minutes and some of it was manufactured yesterday just before the test started.

Aaron A. Feinberg, former State Senator and Dr. Clement's attorney, said it could be produced for 9½ cents a gallon and retailed for 18 cents. He declared that a gallon would drive a heavy machine eleven and a half miles, that it was non-explosive and would not carbonize. Several aeroplane manufacturers were present when the tests were made.

Goodrich Co. Enlarging Factory

Akron, Ohio.—A new building which will be the largest of the 84 in use by the B. F. Goodrich Co., will soon be under construction. It will be 170 x 300 feet, eight stories high. The warehouse will be built next to railroad siding and will have an unloading platform and seven special elevators.

Brolt Aircraft 275 Watt Dynamo Weighs 19 Pounds

In order to fill Admiralty requirements for extra light-weight dynamo sets for a special branch of the Air Services necessitating the full output for long periods or indefinitely if necessary, a new type of self-regulating dynamo accordingly was designed by Mr. Holt, technical director of Brolt, Ltd., of Birmingham, England. This design incorporates a scheme of forced ventilation whereby cold air was continuously blown through the interior of the machine, enabling an output of 275 watts to be obtained continuously at quite a moderatee speed, from a dynamo weighing under 19 pounds. For airship equipment, electrical apparatus has been designed and manufactured which has elicited eulogies from the authorities concerned.

Personal Pars

David Linton Ingalls, of Cleveland, O., has been re-elected captain of the Yale Hockey team next year. He was the only American ace in the U. S. Naval Aviation Service.

Tail Structure of NC Flying Boats Supported by Hollow Spars

Lieutenant Commander W. Starling Burgess, being a thorough yachtsman and well acquainted with the great advantages of the hollow spar, conceived the idea that in the preliminary design of the NCs, the proper way to hold the tail structure would be by a hollow wooden spar.

The Pigeon Hollow Spar Company is the original builder of hollow and laminated wing beams, struts, etc., and first to advocate to the United States Government the great advantages and practicability of hollow and laminated parts.

Lieutenant Commander Burgess' idea was followed by a conference at Washington, and later by an order for hollow-tail booms for experimental purposes. These booms were made and were sent to the Bureau of Standards and tested.

The Pigeon Hollow Spar Company had several talks with Lieutenant Commander Burgess as to the strength required by these tail booms, and it was ascertained that they must carry a loading strain of approximately 3,500 pounds. There were two sizes of booms made, approximately 18′ long, 6¼″ in the center, tapering to 3-⅛″ on the ends, and 5¼″ tapering to 2¾″ on the ends. These spars were constructed in four pieces, glued together with Pigeon glue. The tests were made at the Bureau of Standards, and a report was issued, which is as follows:

Column Tests of Pigeon Hollow Spars

Approx. Length	Diameter ″ Middle	Ends	Weight lb.	Prop. limit lb. Comp.	Deff.	Ultimate strength lb.	Slope of comp. curve in lb.
(1) 17′ 9″	6.25	3.15	25.0	9,000	5,600	15,900	11,050,000
(2) 17′ 9″	6.27	3.25	24.75	9,300	7,100	17,600	10,840,000
(3) 17′ 8″	5.35	2.67	18.5	5,000	2,500	9,030	8,060,000
(4) 17′ 8″	5.37	2.72	19.0	5,600	2,800	10,300	8,410,000

Tns. Lab. No. 0213b18
February 21, 1918.

CHARACTER OF FAILURE

(1) Failed by buckling down at 1/3 point. Column split into five parts at point of failure. Partial compression failure near ends.
(2) Compression failure next to web about 5 ft. .07 in. from end.
(3) Failed by bending. Load dropped to 4,000 lb. and remained there until fracture occurred by crushing over a diaphragm about 4′ from end of spar.
(4) Failed by bending.

Much attention was attracted by the remarkable crushing strain withstood by these tail booms and by the manner in which they split. Not one of the breaks came in the glue joints.

After very successful tests an order was placed through the Curtiss Company for four sets of tail booms for the NC-1, NC-2, NC-3 and NC-4. When the booms were received by the Curtiss Company they were found to be so light for their length that there was much speculation as to their being strong enough for the work required. Another test was made at Washington, and it was found that they stood up to better advantage than the sample set previously submitted, and in no instance did they break where it was thought they would. This was accounted for by the fact that the sample booms had diaphragms every two feet, and the latter booms did not.

The hollow spar was made of practical use of again in connection with the flying boats of the Navy Department. With the original wireless equipment on these boats, wireless messages could be transmitted but a short distance, but with the assistance of hollow telescopic masts which could be raised to a height of 33′, this difficulty was overcome. These telescopic masts were made in four sections which telescoped from one to the other, so that the mast had a height when housed of only ten feet, with a gross weight of only 12 pounds. The first sets were manufactured by the Pigeon Hollow Spar Company.

Both hollow spar and laminated structure have been acknowledged to be the proper methods in building aircraft. This method works to a great advantage by a great saving in weight, and at the same time it adds strength to the structure. By this construction stock is utilized in different lengths which would otherwise be wasted.

The Pigeon Hollow Spar Company has been building flying machines and flying machine parts since the year 1910. On the first monoplane which they constructed in 1910 every strut, longeron, wing beam, etc., was hollow.

The advantages of the hollow spar are acknowledged likewise for all sailing and steam yachts. An experimental set of hollow spars for one of the latest destroyers brought about a saving in weight over the old solid construction of 60 per cent. Practically all the yachts, both English and American, which race for the America's cup, have been equipped with the Pigeon hollow spars.

Personal Pars

A. E. Aurand, formerly designing engineer for the Zenith Carbureter Corp., has been appointed chief engineer of the Claudel Carbureter Co.

Guy W. Yaugham, formerly in charge of production for the Wright-Martin Aircraft Corp., New Brunswick, N. J., has been appointed vice-president and general manager of the Van Blerck Motor Co., Monroe, Mich.

George N. Duffy has resigned as general superintendent of the Canadian Aeroplanes, Ltd., Toronto, to accept a position with the Canadian Cartridge Co., Hamilton, Ont., Can.

Edward A. Sipp, who has been serving as aeronautical mechanical engineer in the production engineering department, Bureau of Aircraft Production, Washington, has left the Government service and is now connected with the Dayton Fan & Motor Co., Dayton, Ohio.

Aerial Mail Postage Reduced to Two Cents

By an order of the Postmaster General today fixing the rate of postage on mail carried by aeroplanes at 2 cents an ounce, which is the regular postage rate for first-class matter, the Air Mail Service was placed on the same footing with all other means of transportation of the mail.

The experiments during the year which have been devoted to the adaptation of the aeroplane to the needs of the regular daily mail service, have demonstrated possibilities for increased efficiency for mail transportation beyond the early expectations of the Department. Since the conclusion of the war, by the use of the Liberty engine and the availability of larger planes salvaged from war stock, mail in greater quantities can be carried as well as greater speed made by reason of the more powerful Liberty motor. Thus, approximately more than 10,000 letters a day for Seattle, San Francisco and Los Angeles and other points on the Pacific coast which fail to connect with the westbound 8:40 p. m. train out of New York are now being advanced 24 hours daily to their points of destination.

In the same way mail from New York that did not catch the 5:15 p. m. train for the West is now being delivered in Chicago in the afternoon instead of the following morning.

Arrangements are now being made to place on the New York-Washington route the three fastest aeroplanes in the Air Mail Service, each having a capacity of 18,000 letters and a maximum speed in calm weather of 132 miles an hour.

The department in anouncing this important change in the Air Mail Service makes the following statement:

"The sucessful operation of the Air Mail for more than one year and the great development for commercial work in the aeroplane in that period, has taken this phase of mail transportation entirely out of the class of experimental work. The great saving of time now effected over the fastest railroad train between New York and Chicago will enable the department to make a saving in car space of more than twice the cost of the operation of an air mail service on that route. It will, therefore, no longer be necessary to charge more than the regular rate of postage for the transmission of aeroplane mail.

"The success of the airship in carrying the mail, together with the great development that has taken place in speed, in quantity of mail that can be carried and certainty of operation, makes it improbable that the air transportation of mail, whether by the Government or commercial air transportation lines will ever be stopped, but will increase from year to year by leaps and bounds, especially over long distances. The great expedition of mail by this means of transportation constitutes a service which the public throughout the country is now demanding, and in course of time will receive, as supplementing the train service.

"For these reasons the air mail has been placed on the same basis with all other means of transportation and the rate of postage made the same as over all other means of mail transit."

G. L. Conner, Chief Clerk of the Aerial Mail Service, is in charge of administrative work

G. L. Conner Has Long Postal Administration Experience

Mr. G. L. Conner, chief clerk of the Aerial Mail Service, has had long experience in postal administration. Mr. Conner has been connected successively with the railway mail, motor vehicle and aerial mail branches of the Postal Service. Prior to this he served three of America's leading railway companies over a ten-year period in connection with the transportation service.

Britain Planning to Send Mails By Air

An aerial mail service to foreign countries is being seriously considered by Great Britain, the Assistant Postmaster announced in the House of Commons July 18.

It might not be long, he said, before mails would be carried to Australia, China and elsewhere in a comparatively few hours, revolutionizing mail transportation.

Colombia Plans Aerial Mails

Colombia plans to institute an aerial mail service over three routes—one between Bogota, the capital, and Barranquilla; the second between Bogota and Pasto and the third between Bogota and Curuta.

Dr. Carlos Adolfo Urueta, the Colombian Minister in the United States, has been advised that bids for carrying the mails will be opened November 20.

Fiat BR Biplane Used in Speed and Altitude Record Flights

The improved Fiat BR biplane with a horizontal speed of 163 miles an hour, was used in establishing the world's three-passenger altitude record of 23,786 feet in 24 minutes.

The pilot of the Fiat BR in both its speed and altitude records was Mr. Brack-Papa, one of the most experienced of Italian aviators. It is the intention of Mr. Brack-Papa to fly the Atlantic on a special fast machine built on the same general lines as the Fiat BR. This machine will have a speed of more than 150 miles an hour.

This BR Fiat machine was designed just before the close of the war to be used as a high-speed long-range bomber. It is equipped with a 700 h.p. 12-cylinder Fiat engine, which is the highest powered engine employed for air work. This machine is a biplane having a wing span of 51 feet 9 inches. The depth of the wings is 7 feet 9 inches, and the length of the machine 32 feet. The aeroplane has a single fuselage carrying a Fiat 12-cylinder 700 h.p. engine driving a tractor screw with a diameter of 11 feet 3 inches. The exhaust pipes which project from each side of the fuselage are encased with sheet metal so as to form a supplementary bearing surface. The struts and the wires are all streamlined. The weight of the machine empty is 2¼ tons and its useful load 1½ tons. Its climbing speed is 1000 metres (3280 ft.) in 3 min. 45 sec.; 2000 metres (6560 ft.) in 7 min. 30 sec.; 3000 metres (9842 ft.) in 12 min. 30 sec.; 4000 metres (13,123 ft.) in 18 min. 16 sec., and 5000 metres (16,400 ft.) in 27 min. In unofficial tests the climbing speed was increased to 13,123 feet in 16 minutes.

AMERICAN COMMERCIAL, TOURIST AND PLEASURE AEROPLANES

AEROPLANE manufacturers in America are turning out aeroplanes especially designed for various commercial uses to which they are to be applied. From the small single-seater sport plane, these recently designed machines range in size up to the 26 passenger-carrying tourist aero bus. They are all of American design and except in two instances, where Le Rhone and Anzani engines are used, the machines are provided with American engines.

Among the ten machines illustrated on the opposite page there are four single-seater sport biplanes, one two-seater flying boat, and a three-seater flying boat, one tandem two-seater, one side-by-side two-seater, one three-seater with two passengers side-by-side, and the 26 passenger tourist biplane. This means that out of ten designs there are but four of similar type. The characteristics sought for in designing these machines have made it necessary for designers to strike off on original lines and it is not to be wondered at that designs so radical have been put forth to meet these needs of civilian aviation.

The commercial uses of these aeroplanes which are now being developed and in many cases already in use, include the following: aerial mapping and photography, express and mail delivery, passenger-carrying, aerial touring, fire and police patrol, advertising, exploring, reconnaissance, news distribution, and exhibitions.

A brief outline of each of the machines shown in the accompanying illustration will serve as a means of comparison:

Aircraft Engineering Corporation "Ace"

The "Ace" is a single-seater sport plane which has put up some very good performances at Central Park, L. I. The machine readily answers the controls and is especially suited for sport flying, light express or mail delivery, advertising and exhibitions.

The most noticeable features of its design are the *I* shape interplane struts and the central skid of the undercarriage. The struts make it easy to line the machine up for there are no incidence cables to adjust. A great deal of hard usage has proven the value of the central skid. In taxying on the ground this skid prevents nosing over, eliminating the ever present danger of damage from overturning. In landing, the heel of the skid acts as a brake bringing the machine to rest after a very short run on the ground. This feature makes the machine suitable for small fields.

The upper plane has a span of 28′-4″ and the lower plane a span of 22′-10″. Chord of both planes 5′; gap between planes 5′-6″. Machine is 16′ long and 7′-6″ high. With a pilot weighing 135 pounds, the machine complete weighs about 650 pounds. In a test flight a sand load of 185 pounds was carried. The "Ace" climbs to 6,000 feet in 20 minutes, and to 8,000 feet in 27 minutes.

A vertical four-cylinder, water-cooler, "Ace" engine is used. This engine delivers 40 H.P. at less than 2,000 R.P.M. The high speed of the machine is about 60 M.P.H. and the landing speed 35 M.P.H.

The Packard Two-seater

In the Packard aeroplane the pilot and passenger sit in tandem. The machine was especially designed for cross country trips but it is of a type suitable for delivery of express and news, reconnaissance, fire patrol, and as an auxiliary for police protection. The machine weighs 1,520 pounds empty and the complete flying weight is 2,167 pounds. The weight per horsepower is 13.5 pounds, and the wing loading 5.6 per square foot.

At ground level the speed is 102 M.P.H., the range for fuel at this altitude being 2½ hours. At 5,000 feet the speed is 100 M.P.H.; this altitude is reached in 7½ minutes and the machine can stay aloft for three hours. The machine has an absolute ceiling of 19,500 feet. A Packard 8-cylinder, 160 H.P. engine is used. Weight complete, 585 pounds.

The Curtiss "Seagull" Flying Boat

The Curtiss "Seagull," formerly known as the "M-F," is suitable for the sportsman and for passenger-carrying at lake and seaside resorts. As an exhibition attraction the flying boat always plays a spectacular role. The passengers are seated side-by-side with dual control. The cockpit is finely upholstered and comfortably arranged.

Span of upper plane, 49′-9″; span of lower plane, 28′-10″; overall height, 11′-9″.

Weight empty, 1,796 pounds; useful load 636 pounds. The speed range is from 45 to 69 M.P.H., and an altitude of 5,000 feet is reached in 27 minutes. The maximum endurance is 325 miles. A Curtiss OXX 100 H.P. engine is used.

The Loughead Sport Plane

Low cost for operation is one of the features of the Loughead Sport Plane. At full speed the fuel consumed by the Loughead 24 H.P. engine is one gallon an hour, which, at a speed of 50 M.P.H. means 50 miles to the gallon; an expense of about 1 cent a mile. The Loughead is a single-seater and weighs but 500 pounds fully loaded. Of this weight 200 pounds represents the useful load which can be carried.

The upper wing has a span of 28 feet; lower wing 24 feet; overall length 19 feet. Fully loaded the high speed is 65 M.P.H., but the landing speed is only 28 miles an hour. The absolute ceiling is 16,000 feet. The flight range is 450 miles.

Control is maintained in an unusual manner, there being no ailerons for the lateral movements of the machine; instead of ailerons, the lower wing sections are arranged to pivot about their axes, accomplishing the desired manœuver.

The machine should find a good place in exhibition work, or advertising, as well as in the sporting purpose for which it was primarily designed.

The Dayton-Wright "Messenger"

Veneer is used to a great extent in the bracing of the fuselage in the Dayton-Wright "Messenger" biplane. It is probably the smallest commercial aeroplane flown in this country. Both planes have a span of 19′-3″ and a chord of 3′-4″. Overall length 17′-6″ and height 6′-1″. Unloaded, the machine weighs 476 pounds; loaded it weighs 636 pounds. The horizontal maximum speed is 85 M.P.H. and the landing speed is 37 M.P.H. In 10 minutes machine will climb to an altitude of 10,000 feet.

An air-cooled De Palma, 37 H.P. engine is used. This is a four-cylinder, "V" type, weight 3.7 pounds per horsepower. Four gallons of gasoline are consumed per hour and the machine has a tank capacity of 12 gallons.

Curtiss "Oriole" Three-seater

The three-seater Curtiss "Oriole" has been made, its designers claim, "for the man of affairs and for his family." Every comfort is provided for the two passengers who sit side-by-side in the forward cockpit which is reached by means of a door in the side of the machine. There are no controls in the forward cockpit and every consideration is given to the convenience and safety of the occupants.

The machine travels at 85 M.P.H. Its span is 36 feet, which is smaller than the average two-seater training plane. Fully loaded the machine weighs 2,188 pounds. The engine is a 90 H.P. Curtiss OX. The "Oriole" answers admirably the requirements of peace time flying combining comfort and safety, with economy, and beauty.

Span of both planes 36′; length overall, 25′; height overall, 9′5″; chord, 5′; useful load, 767 pounds.

The performances with a full load are as follows: high speed at sea level, 85 M.P.H.; at 5,000 feet, 83 M.P.H.; at 10,000 feet, 80 M.P.H. Low speed at sea level, 47.3 M.P.H.; at 5,000 feet, 51.6 M.P.H.; at 10,000 feet, 56 M.P.H. At sea level the economic speed is 60 M.P.H.; at 5,000 feet, 65.5 M.P.H.; at 10,000 feet, 71 M.P.H. Fully loaded the machine climbs to slightly less than 2,500 feet in 10 minutes. The rate of climb is 400 feet per minute.

Endurance at high speed, 4.3 hours, sufficient for a flight of 365 miles. Endurance at economic speed, 6.65 hours, in which time a distance of 393 miles can be traveled.

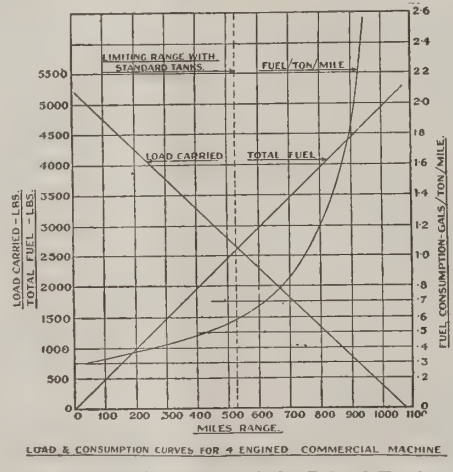
Aeromarine "T-50" Flying Boat

The Aeromarine Model T-50 Flying Boat is known as the "limousine of the air." It is a three-seater boat with an open compartment for the pilot and an enclosed cabin for the two passengers seated side-by-side behind the pilot. The covering of the cabin is with celluloid; the frame is hinged at the middle, so it may be opened from either side. Steps are pro-

(*Continued on page* 943)

AMERICAN COMMERCE AND SPORT PLANES

THE BRISTOL PASSENGER TRIPLANE



FOR commercial purposes, whether for the carriage of passengers or of freight, a special body has been designed and constructed for the "Bristol" Triplane. The passenger car described as the Pullman, is wholly enclosed, whilst the seats are placed on either side of a central gangway. There is ample head room as the Pullman is some seven feet in height, and for each passenger ladge Triplex glass windows are provided. There are also elaborate arrangements for electric lighting and heating. The seats are so arranged as to be easily removable and the space thus rendered available can be utilized for the stowage of luggage and general cargo. The storage room thus available for cargo is 320 cubic feet.

The performances of this model in respect of speed, climb, range and weight carried are approximately the same as for the Bomber riplane. Bearing in mind that the useful weight carried is in inverse ratio to the quantity of fuel carried and the consequent range of flight, it will be seen that, in addition to the two pilots, the machine is capable of lifting a load of 2,700 lbs. together with fuel for a five hours' flight, or, alternatively 4,000 lbs. with fuel for 7½ hours' flight. These figures are based on an economical speed of from 100 to 105 miles per hour, that is to say at three-quarters throttle, leaving a sufficient reserve of power in hand to reach 125 miles per hour if necessary.

In the accompanying graph, "load carried" is in addition to the weight of two pilots, oil and water, but includes gasolene. For oil consumption, divide gasolene consumption by 15.

The main specifications of the Pullman type triplane are as follows:

Wing Area (sq. ft.)		1,905
Wing Span	Top Plane	81′ 8″
	Center Plane	81′ 8″
	Bottom Plane	78′ 3″
Chord of Wing		8′ 6″
Overall Length		52′ 0″
Maximum Height		20′ 0″

Graph of performances of the Bristol Triplane Cargo Machine

Weight empty (lbs.)	11,000
Weight loaded (lbs.)	17,750

When, for the conveyance of mails or other cargo, any or all of the passengers' seats are removed, the following examples give an idea of the manner in which the accommodations may be arranged. These figures may be varied to suit requirements:

14 passengers and 280 lbs. of cargo
9 passengers and 1,180 lbs. of cargo
4 passengers and 2,080 lbs. of cargo
0 passengers and 2,800 lbs. of cargo

The above figures are based upon sufficient fuel being carried for a flight of 500 miles, but if the full quantity of fuel is not taken, the weight of cargo may be increased accordingly.

For commercial purposes it is not desirable that the machine should be flown at its full speed of 120 miles per hour, and a speed of 100 miles per hour (at three-quarter throttle) is recommended as being the most suitable in view of the economy of fuel effected.

Four 410 h.p. Liberty engines are fitted, and any two of these are sufficient to maintain the triplane in flight in case of breakdown of the others. A full set of flying instruments is also fitted, comprising: 2 air speed indicators, 4 revolution indicators, 1 switchbox for electric lighting, 1 watch, 1 compass, 4 oil pressure gauges, 4 radiator thermometers, 4 Liberty switches and voltmeters, 1 altimeter, 1 cross level, and electric lighting set for each instrument.

Personal Pars

Bruce Eytinge, sales-pilot, has had added to his duties those of advertising manager of the Aircraft Engineering Corporation, manufacturers of the "Ace" biplane.

Speaking of records, Captain Roy N. Francis, of the Army Air Service, now on duty in the office of the D. M. A., is believed to hold the record for number of hours in the air. Up to the present time this officer has more than 5,000 such hours to his credit.

Two new appointments have been made in the Information Group of the Department of Military Aeronautics. Major E. L. Jones has been assigned to the Dissemination Division and Major Melvin Hall to the Collection Division. Both these officers served with distinction overseas, Major Hall especially, since he has been on duty with the French, the British and the American forces and seen action from 1914 till the armistice, all along the line from Ypres to the Argonne.

Book Review

THE THUNDER BIRD, *by B. M. Bower.* The further aeronautic adventures of "Skyrider" Johnny Jewell. When "Skyrider" Johnny Jewell won his aeroplane and the love of Mary V. Selmer, he may have thought his troubles at an end. As a matter of fact that had really only just begun, for that cherished plane was to lure him into so many exciting adventures that between them and the demands of Mary V., poor Johnny found his life just one succession of mishaps. Read this interesting story and see where this book gets its title. Price $1.65, post paid.

SOME NOTES ON ENGINE RUNNING

SKILL in engine running is mainly a matter of experience, but a very great deal depends upon simple deduction and logical reasoning.

Every engine trouble is the result of one or more definite causes and as a rule is accompanied by symptoms from which the cause may be deduced. In any case a clue is obtained from the manner in which the engine fails. For example, a sudden stoppage, unaccompanied by the obvious symptoms of internal breakage or "seizing up," can only be due to complete failure of fuel supply, or ignition system, and in such a case it would be against the dictates of common sense to open up the engine, or even to inspect the spark plugs.

In the hands of a capable mechanic an engine in good condition should start with certainty and ease. When the engine is running, symptoms should be detected, and recognized, before any trouble fully develops, and in case of failure resulting from the more common causes, the fault should be located immediately, or at the most, after a brief inspection of the engine.

Starting Up

Before starting an engine, turn it over once or twice, note that the valves are not sticking, and that the compression is normal. See that there is a sufficient supply of gasoline and oil for the run, and that the oil is of the right quality and consistency. In winter it may be necessary to warm up the oil, or, in the case of castor oil, to thin it down with methylated spirit, which may be added in a proportion not exceeding half a pint to the gallon. In water cooled engines see that the water circulating system is in order, and contains the proper quantity of water. It is usual to allow about 2% for expansion of water when hot.

When an engine has been standing, its cylinders will be filled with air or inert gas, and, in order to start up, this must be replaced by an explosive charge. In stationary engines this is done by turning the engine, with air intakes closed, and gasoline on, when a rich mixture will be drawn into the cylinders, and the inert gas expelled. In rotary engines this method alone is not practicable, owing to the large volume of the crank case through which the mixture passes on its way to the cylinders. In engines of this class, therefore, it is usual before starting, to "dope" or "prime" the cylinders by injecting gasoline through the exhaust valves. Some stationary engines also are fitted with a priming pump, which sprays gasoline into the induction pipes, and so facilitates starting up.

Existing engines are started up by one or the other of the following methods:

(1) Propeller swinging (rotary and low-powered stationary engines)
(2) Hand-driven starting magneto
(3) Mechanical hand starting gear
(4) A combination of (2) and (3)
(5) Compressed air.

Propeller Swinging

The usual procedure is as follows:

The mechanic before approaching the propeller, calls out "Switch off. Gas on. Air closed."

The pilot turns the switch knob downwards, turns on the gasoline, adjusts the throttle, closed the extra air intakes, and repeats the words of the mechanic.

The mechanic, then gripping the propeller by each blade in turn, pulls the engine over, in its normal running direction, until the cylinders are charged. He then stands clear and calls out "contact."

The pilot turns the switch knob upwards and calls out "contact."

The mechanic then grips the propeller blade and making sure that he has a sound footing, pulls the engine sharply over compression and stands clear.

Hand Driven Starting Magneto

The procedure is as above but after the word "contact" the mechanic remains standing clear while the pilot starts the engine by vigorously cranking the starting magneto. (The starting magneto should not be left "on" when the engine is running.)

Mechanical Hand Starting Gear

The cylinders are charged by turning the engine with the hand gear. While the engine is being turned over as fast as possible by this means, the switch is put "on" and the starting handle is thrown out of gear.

Mechanical Hand Starting Gear with Starting Magneto

In this case the starting magneto is usually geared to the starting handle and is switched "on" when the cylinders have been charged as above.

Compressed Air

Air under high pressure is supplied to a small starting motor or directly to each of the engine cylinders in turn through a distributing valve driven by the camshaft. The air cock is opened and the engine is driven by compressed air until the cylinders are charged when the switch is put "on" and the cock closed.

Failure to Start

This may be due to: (1) Initial impulse lacking in vigor. (2) Incorrect adjustment of throttle. (3) Incorrect mixture. (4) Engine out of order. To start an engine it must be swung over compression at a reasonable speed. A mechanic exhausted by unsuccessful attempts to start a stubborn engine will be unable to put sufficient energy into the swing and should make way for a "fresh" man or take a short rest while looking over the engine to make sure that everything is in order.

Most engines will start best with a particular adjustment of the throttle which should be carefully noted. Where the carbureter has a slow running adjustment it is usual to start with the throttle quite closed. In other cases the throttle is set partly open, usually about one-quarter to one-third but never fully open.

An explosive mixture contains approximately 18 volumes of air to one of gasoline vapor and if the gasoline vapor is present in a much greater or lesser proportion the mixture will be too strong or too weak and will explode with greatly reduced force or will not explode at all. The vaporization of gasoline is assisted by heat and when starting a cold engine (particularly in winter) the spirit will be only partially vaporized. This results in a weak mixture unless a considerable excess of gasoline is provided for by flooding the carbureters or "doping" the cylinders or induction pipes. In warm weather and especially when starting with the engine hot it is easy to get too strong a mixture into the cylinders. When an engine fails to start for this reason, it should be turned over in the anti-normal direction through two or more revolutions in order that the mixture may be weakened by the addition of air drawn in through the exhaust valves.

In looking over an engine that fails to start ascertain that the ignition system is in working order and that the plugs are clean, sound and correctly coupled to the distributor. See that there is no loss of compression through leaky valves, plugs, etc., and look for possible air leaks in the induction pipe joints. As a final measure the timing should be checked.

Table of Engine Running Faults

Symptom	Fault	Possible Causes, Remedies and Remarks
Missfiring, Regular	Plug or Connection faulty	Cracked insulation. Points sooted up, too far apart, burnt away or fused together. H.T. connection broken or short circuiting. (To locate fault run engine for a few minutes and find coolest cylinder. If in doubt change all plugs.) (*See below.*)
	Loss of compression in one cylinder	
Missfiring, Irregular	Exhaust valve sticking	Dirty or damaged valve stem or guide. (Clean stem or as a temporary measure moisten with paraffin or gasoline. Valve rocker stiff on pin. (Clean and lubricate or renew if necessary.)
	Carburation faulty	Mixture much too strong or weak. (If 1 or 2 cylinders only may be due to air leaks in induction pipe.)
	Magneto contact breaker sticking, making bad contack, or out of adjustment	(Clean contacts, ease moving parts and adjust.)
	Distributor faulty	Segments short circuited or partially insulated from brush. (Clean with gasoline.)

WOOD PROPELLER CONSTRUCTION

By PORTER E. STONE, M. E.

MUCH has been written about the design and theory of air screws made of wood, but very little has appeared about the construction and methods used to obtain the best results. Probably the one thing which designers and engineers forget, is that it takes time to make and thoroughly season a propeller during construction. When in production, it should require at least eight weeks as a minimum, from the time the lumber leaves the dry kiln until the club is ready to ship.

A great many people have the idea that propellers are a hard and difficult thing to make. After having handled about seven thousand, the writer considers it an easy manufacturing proposition. The principal thing to remember is to take plenty of time and be sure of every step. Specifications as furnished by the Bureau of Aircraft Production and Steam Engineering Department of the Navy, were not at all difficult to adhere to. The tolerances and balances were not exacting beyond ordinary manufacturing facilities. While the writer does not agree with all methods recommended, if they are accurately followed, it will be possible to produce good propellers in quantity.

The first fifty or so propellers which are manufactured of any design, ought to be watched with great care, as all designs and types have their own peculiar characteristics, i.e., changes in pitch, track, etc.

The object of this article is twofold, first to help the designer understand a few of the problems the builder has to confront; second, to give new ideas to propeller manufacturers. So let us follow the lumber for the club from the time it enters the yard until the propeller is shipped.

Lumber

Propellers can be made from any timber which has a uniform texture and a high tensile and sheering strength. In the United States, poplar, quarter-sawed white oak, birch, cherry, walnut and true mahogany from Florida, Central and South America, are included in this class. Poplar was found to be highly efficient on the Mexican Border, on account of the extremely dry climatic conditions. Quarter-sawed white oak makes a propeller which weighs the most, birch coming next, then walnut, cherry and mahogany. The streaks in cherry have been found not to be a serious defect. The great difficulty found in using mahogany is that there are small wind breaks which are very hard to see in the rough lumber. Spanish cedar and baywood are oftentimes mixed with mahogany, probably a small amount in a propeller would not injure its quality, provided the wood is of good texture.

Considerable discussion has been caused this last year by the fact that lumber mills have not taken enough care in sawing and cutting the log. That is to say, the man on the saw carriage was not careful to place the heart of the log parallel with the saw. This oftentimes resulted in a diagonal cut and, of course, made the lamination appear to have a diagonal grain, which was really true of the board itself. In quarter-sawed white oak, considerable bastard sawed lumber has been found.

Grading Lumber

When the lumber comes from the mill to the propeller manufacturer, considerable care should be taken in grading the quality of lumber. Care should also be taken to keep each car load of lumber together, and so marked that the kiln man can easily designate each car load lot. The mill man should be careful not to mix different season's cuttings, as old lumber should not be mixed with green timber. The yard man of the propeller manufacturer, when he finds these conditions existent, should bring them to the attention of the kiln man.

At this time the propeller designer should become familiar with the percentages of widths of the stock, as small deviations in lamination layout will save much lumber in the manufacture. That is to say, laminations sometimes work out so that they are wider at the ends than the hub. As it is impractical to glue onto a lamination at the ends, this may necessitate a large percentage of wide stock, in fact, one or two inches larger than the lamination at the hub. A small change in the design of the propeller, or the layout of the lamination would have caused a decided saving to the manufacturer, as wide widths are harder to secure than the narrower stock.

Thickness of Lumber

Lumber of half inch to one inch thickness gives the best results. Personally, the writer has found four-four rough stock to be the best, taken as a standard, dressed on both sides, and resulting in a thirteen-sixteenth thickness lamination. With this measurement as a standard, the designer could produce a lamination layout and make the propeller with that in mind.

Yard Piling

A great many yards are not piled in a scientific manner. There is not enough timber used, together with a heavy enough foundation to keep the piles from settling at one corner or at one end. This results in giving the boards, after a duration of sometime, a permanent set. Also, in some yards it will be found that the long boards are allowed to overhang considerably, which does not benefit the strength of the lumber. A neatly trimmed pile, with a firm foundation gives the best results. A great many yard tracks are not laid straight, or level, so that when the kiln trucks are piled in the yard, there is a twist in the truck; thus, when the kiln truck is placed in the kiln, which generally has a track in very good condition, the boards are steamed and dried with a certain amount of twist. In piling on the kiln truck, after considerable experimentation, the writer prefers twenty-four-inch spacing between cross sticks, and not in excess of thirty inches. The cross sticks themselves should be not less than one inch square, and care should be taken to place the sticks directly one above the other. Short boards should be blocked on the end, so that they will not get in wind from the steaming and drying process. If good care is taken in piling the trucks, it will save considerable time when the lamination gets to the joiner, as a good straight flat board is preferable to one which is sprung and in wind.

There are several methods of piling on the kiln trucks, such as chimney, staggered, and straight, any one of which are adapted to any type of kiln. However, each type of kiln will give better results with one than the other.

Kilns

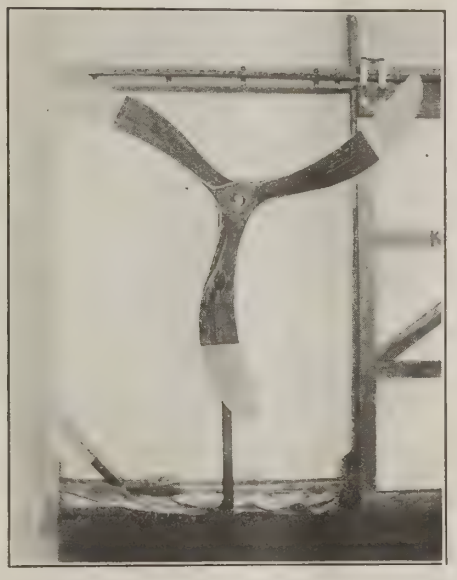
There are three principal things to remember in all dry kilns. First, that hot air is lighter than cold air; second, that moist air is heavier than dry air; and third, the greatest quantity of air which can be moved equally throughout the kiln. Together with these, there must be a good humidity control, and last, an automatic temperature-regulating device. In starting a kiln, for the first time, it is best to take punk sticks to test the circulation throughout the kiln, seeing that approximately the same amount of draft is in equal heights of the kiln, as it is often found there are dead spots in the kiln, which naturally results in poor local drying. For propeller stock, any type of kiln will usually give fair results. While the time taken by the ordinary box kiln with natural circulation is slightly greater than the re-circulating types, if handled with a

Glued up propellers in block form

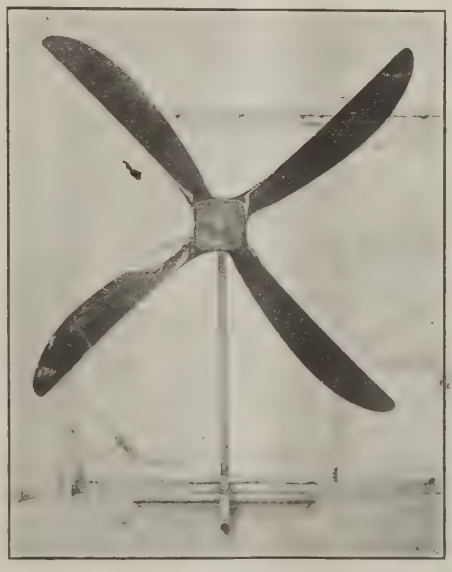
fair degree of care, and plenty of time taken, it will dry the lumber. The re-circulating type kilns, such as the Tieman and fan types, give the best results in the shortest possible time. It is very desirable to allow the lumber to cool off in the kiln before removing it. That is to say, shutting off the heat in the kiln, and allowing the lumber to cool down for twenty-four hours or so, not having the temperature of the lumber higher than 90°. If it is higher, and there is much dampness in the air outside, while cooling, the lumber will absorb dampness quite readily.

Testing and Samples of Lumber

It has been found advisable to have one sample test for every three thousand feet of lumber in the kiln. In testing lumber, it is best to cut off at least two feet from the end to eliminate end drying in the

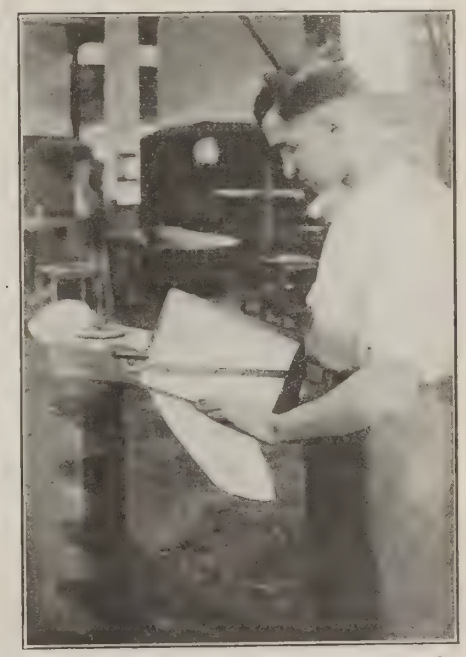


A unit spirit level protractor for use with level bench without a pitch card



yard pile. Next, cut off about two feet, or a board that will weight more than five pounds and not greater than ten. From this board, take off two one-inch disks, and weigh the disks immediately upon sawing. It is advisable not to saw with a circular or trim saw, but use a band saw where possible, as the heat of the smaller high-speed saws tend to dry the disks; thus they will lose a small amount of moisture. After cutting off the disks, coat both ends of the two-foot test board and weigh as soon as possible. Any good tar or asphaltic base, such as roofing cement, can be used for coating the ends of the boards. The sample boards should be distributed throughout the kiln, not in exposed portions, as there will naturally be a difference of about two per cent in moisture content of the test boards and the lumber as a whole. That is to say, the test boards and sample boards taken from stock after kiln drying will weigh less by one to two per cent than the stock tests. Roughly speaking, a good kiln should dry quarter-sawed oak from fiber saturation, from five to seven per cent moisture content, at the rate of three-quarters to one per cent a day. Other woods can be figured at from one to one and a half per cent a day. Of course, the lumber can be pushed at a higher rate, if desired, but it is unwise to do so.

A practical type of balance stand used at the American Propeller factories

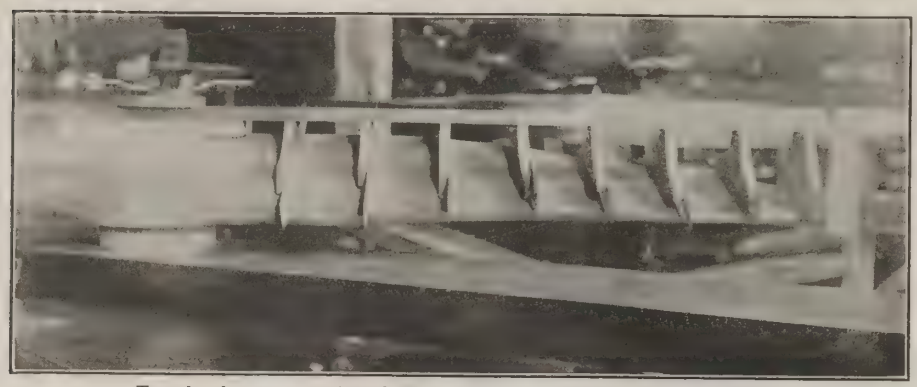


A Paragon torsion pitch three-blade propeller on a balance stand

A four-bladed propeller awaiting one of the final inspections

The disks, after weighing, should be put in an oven, with a temperature of approximately 180° to 200° F. and allowed to remain for twenty-four hours. It is not advisable to cut the disks in small pieces, as is often-times done. The one-inch square disk, the width of the board usually gives a very close result. After the disks have dried for twenty-four hours, re-weigh them, place them back in the oven, and allow them to dry at least six hours again. Then weigh them again, and if they have not lost in weight, or are very nearly constant, take that figure and subtract it from the weight green. Then divide by the oven-dried weight, which will give the percentage of moisture in the disks. From this it is easy to calculate what the oven-dried weight of the two-foot test boards should be. Having given the weight of the green test boards, it is then only necessary to weigh the test

Universal protractor for use with level bench using pitch cards



boards at least every two days and figure the percentage of moisture in the test boards at that time. From experience, it has been found desirable to mark the weight and percentage of moisture directly on the test boards.

Shop Conditions for Lumber

It is advisable after cooling off the lumber in the dry kiln to pile immediately on cross sticks in the shop proper, so that it will attain shop conditions in regard to humidity and temperature, as soon as possible. The lumber must not be put in a cool, damp basement, or outside shed. It should be placed where there is good free circulation, and where there is the same amount of humidity as in the shop proper. If the lumber is to be used at once, it can go directly from the dry kiln to the manufacturing of the propeller, in which case it necessitates a longer time in equalizing after the lamination is cut out and dressed.

Laminations

After having carefully made the correct lamination layout, and adding correctly the amount of extra stock needed in the manufacturing, then mark out the lamination. In mahogany and quarter-sawed oak it is a good plan to join one side of the lamination first, then plane or dress the

Templet for ascertaining the accuracy of the pitch of the propeller

other side before marking out the lamination.

In rough lumber it is quite hard to see the minor defects. After sawing out the lamination, then drill a one-inch hole for the center of the hub.

Great care should be taken in laying and marking out the lamination, as a careful man at this point will save much time later on in the manufacture and unnecessary expense. When band sawing the sides, save the side shorts for the hub wideners, to be used with the same lamination, cut from the same board. In splicing laminations it is expedient to match boards of the same texture and density. Next, make the serrations for the hub wideners when it is required. It is well to check the serrated joints by reversing the hub widener, to see if the serrations match up in both positions. Then glue on the hub widener, allowing the lamination to stay in clamps for at least three hours. Re-band saw the lamination, then dress to size, checking the planer knives for parallel every time they are ground.

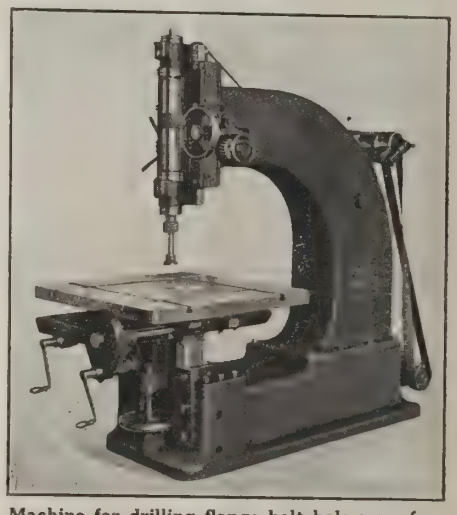
Tooth plane and then pile the laminations for equalizing. If the lumber has been dried to a variation not greater than three per cent., it is safe to say that ten days is the minimum required at this time for equalization. If the stock shows slight case hardening, it is not objectionable, especially in quarter-sawed oak. It is advisable in piling, to use a one by one cross stick and from four to five sticks. After ten days, remove several laminations and test carefully for moisture content. Density tests can best be made by weighing the lamination and sub-dividing the weights into three groups, A. B and C. Although the writer believes an expert grader will obtain better results by grading to texture than in grouping for density by weighing. While the density and texture are closely allied, the texture is generally more of a factor in determination of strength of a propeller than specific gravity or density of the wood.

After the laminations have been sorted by groups or grades into three piles, then assemble, placing them on a balancing stand or balancing pin. While this is only a rough balance, exceptional results can be obtained. First, balance horizontally; then check vertically, for exceptional density streaks in laminations. Each lamination should not be balanced separately, as the propeller should be treated as a whole, not each separate lamination. Reverse ends of lamination until balanced.

Gluing

Now that the propeller is assembled, separate the laminations, carefully marking one end of each lamination for reassembly. Place them in the hot box, which should be about 130 to 140° F. and merely heated by steam pipes, not introducing any extra moisture than is ordinarily in the glue room proper. Allow the laminations to stay from 10 to 20 minutes, so they will become thoroughly warm to the hand on the outside, in order to avoid chilling the glue. Of course, the hot box should only be used with hot glues.

It has been found that the cowls which extend the entire length of the laminations are preferable to the small blocks which are sometimes employed. Cowl boxes are very good where enough pressure can be applied. There has been considerable difficulty in obtaining pressures as great as fifty pounds to the square inch at the hub. Presumably, a few manufacturers have had some trouble with glued joints at the hub.



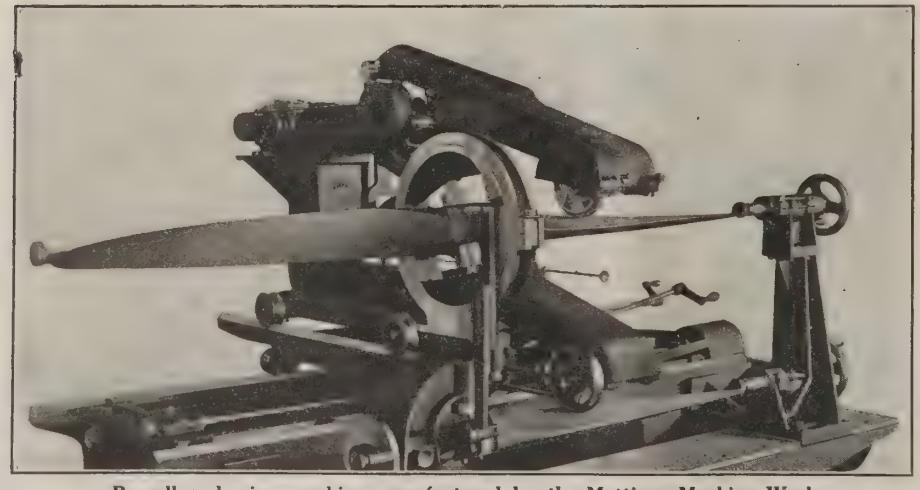
When gluing quarter-sawed oak, it is expedient to have the lumber dried from five to seven per cent., and great care should be taken in the steaming process in the dry kiln, as all tannic acid which can be removed is best for the glue. When oak contains a high percentage of moisture, and considerable tannic acid, the glue will gradually deteriorate, especially if it is slightly alkaline.

The propeller should not be removed from the retainer or clamp in less than twenty-four hours. While the glue sets in a much shorter time, it has not thoroughly dried and reached a high tensile strength. When the retainers have been removed, glue on any scabs or veneers which are necessary, then drill the large hub hole to within about one-quarter of an inch of full size.

Plane the pitch surface of the hub, then center for the first cut on the carving machine. Care should be taken to obtain a true center line passing through the center of the hub hole. After the first cut, hang the propellers horizontally for two weeks on a rack in the shop.

Carving Machine Methods

In the earlier methods of propeller manufacture, most propellers were cut out by hand, and today, in orders of less than



Machine for drilling flange bolt hole manufactured by the Mattison Machine Works

ten, it would not pay to make up patterns and templets necessary for a carving machine. There are several small rotary hand cutters which can be used to some advantage. The carving machine can be divided into two general types, where the propeller knives move in relation to the propeller, or where the propeller moves in relation to the knives. Carving machines generally cut with the grain, distinguishing them from the turning lathes, which cut cross the grain, either one surface of the propeller at a time, or cutting completely around the propeller.

Machine Work On Clubs

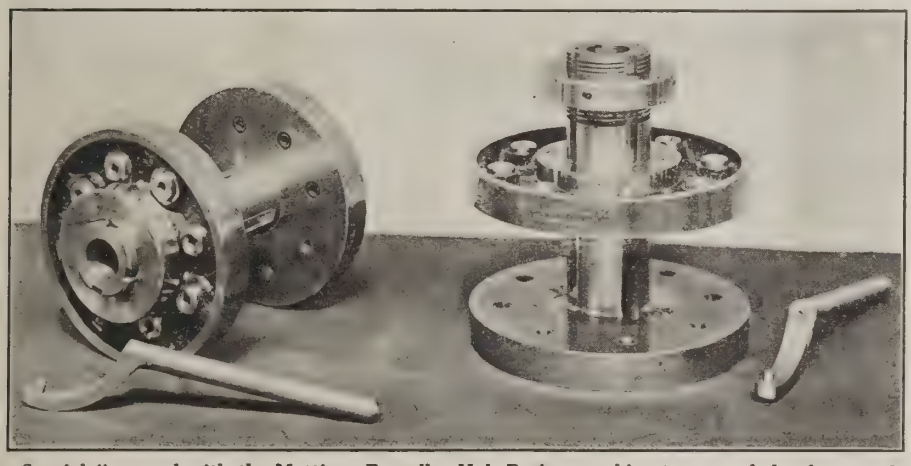
When the propeller has been thoroughly seasoned in the drying-out process, it is necessary to very carefully re-center for the second machine cuts. If this is not done, it is very easy to undercut one side of the propeller, not giving enough stock to finish within the limits. The second cut from the ordinary carving machines or turning lathes can be almost to size.

Probably the best practice is to drill the hub hole to size and oil, then the fillers for the hub flange on both sides of the propeller. While the filler is only necessary on pitch side, from continual handling, the advantage of the filler on the camber side will be seen. The old method of drilling the flange bolt holes from either side of the propeller has been superseded by the new type of machine,

Propeller shaping machine manufactured by the Mattison Machine Works

which will cut the flange bolt holes completely through from one side.

The next operation is exceedingly important, that is the shaper operation. Place the propeller on the shaper pattern, using the second machine cut center holes, and a spindle to fit the large hub hole, placing the propeller pitch side down, the pitch side having been accurately dressed before. It is not necessary to leave more than one-eighth of an inch over size in width at the hub. If the shaper pattern is carefully made, it saves considerable trouble in getting face alignment and in obtaining a vertical balance.



Bench or Hand Work

There are several methods used for working the propeller out by hand or finishing the propeller. The first one is to have a bench which is level in all directions, and have the block upon which the propeller rests parallel with the bench, using an ordinary wooden protractor with templets to fit the oval or round parts of the propeller. The edge alignment is taken by measuring up from the bench at each station. The next method is to use an ordinary buck with a spirit level protractor and metal or wood templets for each station. Some difficulty arises with the buck method of manufacture, as it is rather hard to define the center line, especially when it is nearer one edge than the other, and then get the protractor to read 90° to the center line. While the discrepancy is not very great near the tip, it has caused a difference of a quarter of an inch in width of the propeller at the second station from the hub, because the protractor or templet was not square to the center line. Both of the above methods necessitate having the pitch face parallel to the camber face of the hub. The writer thinks the propeller should be made from the pitch face of the hub only, and on those lines has constructed a special jig which will allow the propeller to be manufactured from the pitch face only. The jig can be used at any possible position of the propeller. It will determine the center line by using a dowel to go into one or more of the flange bolt holes. Start at the hub and work out with the jig. The photograph shows only one-half of the templets. The round or camber side is hinged to one corner of the templet shown, preferably the leading edge. The propellers are made completely from the pitch hub surface, and when finished, there is a true center line from tip to tip of the blades, the face alignment, edge alignment, pitch, and necessarily the track is correct for all stations. Where a trigger hole is used, it is determined from the jig, and if there is a slight mistake in boring the flange bolt holes or trigger hole, the jig will show before any hand labor is done on the propeller. By a few details not shown, it is possible to have tolerance readings taken directly from the jig.

In balancing the propellers in the white, it is advisable to balance or scrape on the pitch side, as from an engineering standpoint, the most effective work is done by the camber side. After the propeller has been balanced, it is then time for the first careful inspection by the manufacturer, as to tolerances, etc. All propellers change pitch and shape during the first forty-eight hours, after coming off the bench. Each design has its own particular characteristics, which will have to be worked out from experience only. When these characteristics are known, they can easily be corrected by the workman on the bench. After checking the propeller at the end of forty-eight hours, it is then expedient to fill as soon as possible. The kind of filling depends on the kind of wood used.

Tipping Propellers

There are several methods of putting metallic tips on propellers. Copper and brass are most commonly used, although in a few cases aluminum has been used. After considerable experimenting, the best method seemed to be the use of both screws and rivets. Where only screws have been used and the metallic tips have been removed, it has been discovered that the heat of soldering the heads of the screws has dried out the moisture in the tips of the propeller, thus causing checks. Rivets, if put in properly, will undoubtedly give good results, although rivets and screws can be used successfully. Rivets should be used where the propeller is not

Unfinished propellers hanging in seasoning room of the American Propeller Co. of Baltimore

thicker than one-half inch, and the screws in the thicker parts of the blade. It is a good plan to countersink the wood with a drill for the screw and rivet heads. On some propellers it is not advisable to recess the full width of the blade, because the double recessing thins the blade. In soldering the screw and rivet heads, care should be taken not to use too much acid, as the acid has been known to cause detrimental results to the wood and glue. Probably the best method to be used in tipping a propeller is to recess the pitch side only and router on the camber side of the blade. If proper care is taken when putting in the rivets, no splits will occur. Care should also be taken with the soldering not to get too much heat, as there have been cases where the metallic tip became so warm that it scorched the wood underneath.

Metal tips should not be used except where there is a water spray or where the propeller is liable to get too near the ground. The leather tips are far preferable for ordinary aeroplane use. Leather can be put on in either of two ways: First, with the hair side of the hide next to the blade, or the flesh side next to the blade. There are good reasons for either way. Pigskin has been shown to produce the best leather tips. These tips want to be inspected quite carefully for defects. It is best to mark out the tips and weigh them, then scive the edges. It is a good plan to put the lap on the camber side on some propellers, and on others it is best to have the lap on the pitch side. It depends entirely upon the shape of the blade. The leather tips should be thoroughly sized, also the wood propeller. When they are dry, coat the propeller and tip with fresh coating of glue, using a warm iron to smooth out the wrinkles and fulness in the leather, unless a very slow setting glue is used. When the leather tip is on, rebalance the propeller, as some leather tips absorb a great deal more glue than others. When the tips have thoroughly dried, shellac them.

Linen tips are very desirable for high speed propellers, as the linen binds the propellers together, and keeps the atmosphere from getting at the glued joints. The linen should be brought up on the propeller as far as possible with the width of the goods, using one selvage edge to go around the propeller at the point nearest the hub, as any tendency to ravel will be eliminated by using this selvage edge. The linen should be thoroughly washed and shrunk before using, as the average linen shrinks from one to two inches in the width of 36-inch goods. While it is not entirely necessary to glue-size the wood propeller before applying the linen, it is advisable. Care should be taken in putting on the glue-size, either for the leather or linen tips, as it will often put the propeller out of pitch. It is best, in most cases, to glue-size the camber side first, let it dry, then glue-size the pitch side. This will often save the propeller from going out of pitch. Before proceeding any further with the propeller, it should be carefully balanced and inspected, since it is impossible to balance the propeller at a later stage.

Painting Propellers

Linen and leather tips should be shellaced, flange bolt holes and hub holes, etc., should be carefully oiled and filled, and transfers placed on the propeller. When they have dried for about forty-eight hours, then give them a coat of varnish. It has been found advisable to use the same spar varnish throughout, thining the first coat with turpentine from fifteen to twenty-five per cent. This thin varnish penetrates the pores of the wood. Next, apply the four coats of finishing varnish, hairing off between each coat. The time required for drying between each coat is determined by each maker of spar varnish. When dull finish propellers are desired, use a brush with pumice and water. The varnish drying rooms should be kept at a moderate temperature and a fairly high humidity.

In hanging propellers in the varnish room it is much better to hang the propellers in a vertical position, since it is much easier to correct for sagging varnish in the horizontal balance than it is to have a sag on one side of the propeller, which causes a bad vertical balance and is difficult to correct. If the propellers are hung in a vertical position, care should be taken to reverse the top and bottom between each coat.

After the propeller has been carefully checked for balance and inspected for pitch and track, it is ready to place in the crate. If the propeller is not to be used immediately, a wax or paraffin substance should be put in the flange bolt holes, also coating the inside of the hub hole.

The box for crating the propeller should be made of thoroughly dried lumber, as green lumber is neither good for the varnish, nor the propeller itself. The type of box depends entirely upon where the propeller is to be shipped, and the length of time it will remain in the box. A propeller must not be expected to last indefinitely in a damp box placed in a cold, damp storage warehouse, as in a short time the varnish will deteriorate, and the moisture open the glue joints.

Conditions in General

Propellers, correctly speaking, should be made for certain climatic conditions where they are to be used. Since this is not possible, it is better to dry all lumber to about seven per cent. as it will be seen from reabsorption curves of lumber, it does not create as many internal stresses as lumber which is naturally dried out by evaporation. Thus, clubs which contain a smaller amount of moisture are much better than those which contain a high percentage of moisture, when they are to be shipped to various climates. Although there are places in the world where lumber containing twenty per cent. moisture can be used with complete satisfaction, other places require only five per cent. moisture, and even then, will cause trouble on account of the extreme dryness and heat.

After having tested a great many completed propellers which had been around the shop for eight weeks or longer, there was found to be very slight variations in moisture content, and even where there was decided case hardening in the lumber, it was entirely relieved in the gluing and manufacture of the propeller. Lumber which is dry comes to the condition of the shop, if it is given enough time in manufacture, that is to say, the shop humidity and temperature predetermine the amount of moisture in the propeller. Lumber which is dried below shop conditions comes within a very few per cent. of that which dries down in the shop. There will only be a variance of from one to two per cent.

In the pamphlet published by the Signal Corps, U. S. Army, Inspection Department, entitled: "Information for Inspectors of Airplane Wood," and prepared at the Forest Products Laboratory, Forest Service, dated 1918, page 43, there is a composite curve showing the moisture content of woods by different humidities and room temperatures.

During the process of manufacture, propellers should be kept in a horizontal or flat position on a shelf, or on the floor, as the variation in room temperature and humidity, from top to bottom, causes the propellers to change unequally.

The shop should be kept at as near an even temperature as is feasible, although variations from night to day of from ten to fifteen degrees will not materially hurt the propeller. The main thing in the shop is to watch the humidity not to get too great a variation, or, in other words, keep the humidity as nearly constant as possible.

Balancing Stands

There are two types of balancing stands in use, one using the knife edges about eight inches long, the other using the roll type bearing. Either will give satisfactory results, although the knife edges will give less cause for dispute in balancing. The knife edges should be about one-thirty-second of an inch wide, of hardened steel and about eight inches long, parallel and level in both directions, and checked by diagonal leveling. The stops at either end should be tested very carefully with a square to see if they are at right angles to the knife blade edges. If they are not, when the propeller is rolled on the edges, the horizontal axis of the balancing mandrel will not be at right angles to the knife edges. Probably the best type of balancing mandrel is the two-piece tapered or cone type. The rolling part of the mandrel on the knife edges should not exceed one inch in diameter. Considerable discussion has taken place as to the vibrations received or transmitted to the balancing stand. It has been discovered that if both knife edges receive the same vibration at the same time, the propeller will balance irrespective of the vibration of the knife blades, such as vibrations imparted by machines, etc., in the building.

The most satisfactory propeller to build is one which has a low pitch angle, for it is more certain to stay in pitch and track. High-pitched propellers are hard to keep in pitch and track because too much end grain is exposed, allowing the propeller to dry out unequally which results in a continual twisting action in the propeller. Three and four-blade propellers should be built in the detached blade method. That is to say, each blade being built separately and dove-tailed together by dowels and keys. However, four-blade propellers can be built as two separate two-blade propellers and halved together at the center. Since the speed of three and four-blade propellers is never excessive, the detached method is preferable, not only from the manufacturers' point of view, and shipping, but also from the aviator's standpoint, as it is possible to replace one blade if it is damaged, in place of discarding three or four.

Summary

In summarizing the methods used and the care to be taken in manufacturing propellers, there are a few points which ought to be emphasized. These are namely: careful grading of the lumber, kiln drying (the United States Government having shown the woodworking industries the correct processes), sorting and grading laminations, balancing laminations, gluing, shaper operations, workmanship and final balance. If these essentials are followed carefully, the manufacture of good propellers will result.

The foregoing suggestions are adaptable to the manufacture of propellers in quantities. Small orders should be treated merely as experimental work.

NAVAL and MILITARY AERONAUTICS

Army Plans Flight Around Country's Border

The most extended flight yet planned by the Air Service of the U. S. Army, in the interest of recruiting, charting of routes, and the locating of landing fields, is contemplated by Lieut. Col. R. S. Hartz, J. M. A., A. S. A., commanding officer at Bolling Field, Washington, D. C.

Colonel Hartz will take with him as reserve pilots Lieut. Ernest E. Harmon, R. M. A., A. S. A., Lieut. Lotha A. Smith, R. M. A., A. S. A.; also as a mechanic, Sgt. John Harding, Jr.

The aeroplane used will be a U. S. Martin Bomber.

The flight as planned will total 7,805 miles as follows:

Washington, D. C., to Miami, Fla....1,120 miles
Miami, Fla., to San Antonio, Tex....1,140 miles
San Antonio, Tex., to San Diego, Cal..1,129 miles
San Diego, Cal., to Seattle, Wash....1,170 miles
Seattle, Wash., to Duluth, Minn.....1,375 miles
Duluth, Minn., to Augusta, Maine...1,345 miles
Augusta, Maine, to Washington, D. C.. 535 miles

Total .....7,805 miles

The flight will not be direct between cities, but will vary according to considerations and demands to be determined by Colonel Hartz.

Summary of Flight—Miles (estimated), 7,805; States in which flights are to be made, 31; cities passed over or near, 95. Passed over or near the following: National lumber reservations, 29; government projects, 7; water sheds and drainage slopes, 9; mountain ranges and mountains, 36; oceans, gulfs, bays, seas and lakes, 48; railroads, 27; rivers, 88; transcontinental routes, 13; miscellaneous, 6.

The Air Service Photographic Recruiting Expedition

Forty-six cities and towns in six states, Delaware, Maryland, New Jersey, Pennsylvania, Virginia and West Virginia, will be visited by the photographic recruiting expedition which will leave Langley Field, Va., on or about July 22, 1919.

The expedition will travel in five Curtiss H aeroplanes, accompanied by a motor truck and lorry. The truck and lorry will be a complete photographic developing and printing establishment containing all the latest apparatus for the production of finished work and a place where recruits may obtain their first insight into the work performed upon the film and plate after it is taken from the camera.

Distribution of Victory Medals Delayed

The War Department authorizes the following statement:

The distribution of Victory Medals is delayed. In view of the large number of applications now being received, attention is called to the fact that Victory Medals will not be ready for issue for several months. The method of distribution has not been determined, but it will probably follow the general scheme now being used for the distribution of the Victory Button. Wide publicity will be given to adopted scheme when medals are ready for issue. Applications for medals should not be made until that time.

Resources of Air Service in Equipment and Personnel Officially Reported

The War Department authorizes publication of the followig information on the service plane resources of the Air Service:

On March 1, 1916, the total resources in planes of the Aviation Section, Signal Corps, was 13 aeroplanes, 4 hydroplanes, and 1 flying boat.

On March 19, 1916, the first aero squadron went into Mexico with eight Curtiss JN-3 planes, a type now inferior to the primary training plane. After being in there two months, four more planes were shipped to them.

At the present time there are on hand in the United States 1,240 battles planes in serviceable condition; enough to make approximately 50 squadrons. Besides these there are in storage 862 battle planes that could be put into commission almost immediately.

The advanced training plane, of the type now used for forest patrol, could if necessary be used as an observation plane. Of these there are 653 in commission at the fields, and 156 in storage. A total of 52 squadrons of training planes could be assembled.

The resources of the Air Service in planes are as follows:

Type	Designed for	Number in commission	In storage, with motors taken out	Total	Number of squadrons possible
DH-4	Observation

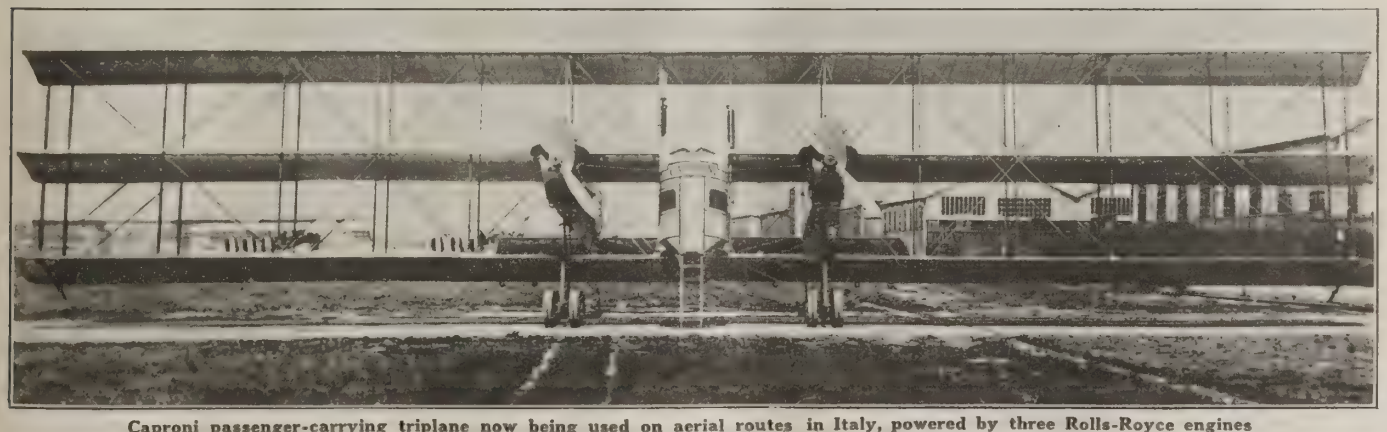
S4-C	Advanced training	400	...	400	16
Total.....		2,339	1,075	3,414	136

There are in the United States to-day 1,394 flying officers. This number includes flying officers on staff duty, etc.

Information on the number of planes available in the Southern Department is given herewith. This, however, is not an accurate indication of strength immediately available, due to the fact that while there are sufficient planes and pilots for the planes, there is not sufficient enlisted personnel to take care of them without transfer from other branches of the service or recall of men furloughed to the reserve.

There are on duty now about 73 men with a squadron of ten planes and two or three other squadrons are being organized at various points in the Southern Department.



Following is a table of planes available, by types and fields, in the Southern Department, showing a total of 788 classed as active planes and 878 obsolescent. The 788 would be available for immediate use, and 878 could be used in addition if necessary.

Special Orders Nos. 150 to 155, Inclusive

The appointments on May 12, 1919, of the following-named Air Service officers, United States Army, are confirmed.

To be first lieutenants, Air Service: Thomas James Abernethy, Neil J. O'Leary, Charles W. Baker, James LeRoy Zimmerman, Sam Love Ellis, Lyman T. Greve, Marion Francis Hart, David P. McDaniel, Robert Ross, John Andrew Farrell, Russell Milton Hayes, Walter Augustus Stoever, Glenn Scott Cobb, Miller Smith Tyson, George Earl Marshall, Leonard Sullivan, David A. Kohler, Roy Bazanquith Ormond, Roscoe Turner, Edwin Maddox Hooper, Tarry E. Montgomery, Byron Thurman Johnson, David Wilber Lewis, Gilbert Shaw Graves, Jr., Raymond Ashton Mitchell, Galen B. Croxton, George T. Marsh, William Raymond Flourney, Harry Pope Clarke, Jr., Carl Browne Squier, Raymond Keran O'Brien, Douglas R. Denman, James Lytle Hamilton, Merle William Bogert, James A. Reardon, James William Flanagan, Roy Frank Jehl, Charles Thomas Somerby, Leon J. Soisson, Lucius Bowen Nichols, Richard H. Dietrich, Isaac Williamson Baugh, Robert Butler Lindsey, Allen Martin Ham, Leo B. Gape, Francis Fleming Taggart, Harvey Hodges Holland, Raymond

Caproni passenger-carrying triplane now being used on aerial routes in Italy, powered by three Rolls-Royce engines

FOREIGN NEWS

Handicaps in the London Aerial Derby

From an inspection of the Timekeeper's table for the Aerial Derby, flown on June 21 last, the following points of interest are elicited:

The times made for each lap by individual competitors were very consistent, proving that in each case a good course was flown. The only exceptions were Capt. Gathergood (No. 7) and Lieut.Col. Henderson (No. 4). The former increased his speed of 126.42 m.p.h. for the first lap to 132.34 m.p.h for the second. His average speed for the total distance of two circuits was 129.38 m.p.h. The latter was compelled to make a temporary landing at Hounslow on his second round for adjustments, which explains the discrepancy in his lap times; but for this he would probably have come near to winning the sealed handicap. The fastest lap was made by Capt. Gathergood, viz., 42 mins. 50⅗ secs. The average speeds stated above are, of course, equivalent to considerably greater speeds on the straight and in calm air. The turning points reported that, with one or two exceptions, all competitors flew low and close.

Having regard to the great disparity in the speeds of the competitors, which ranged from 70 to 133 miles per hour, the handicapping must be adjudged a good one. Only 17 minutes separated the first and last of the seven machines which completed the course, and less than five minutes separated the second and sixth Maj. J. H. Ledeboer and Mr. C. T. Glazebrook, the official handicappers, are, therefore, certainly to be congratulated on their work.

No prize was offered for the fastest time third place, but it is understand that a special trophy will be presented to Mr. Manton for this by the Grahame-White Co., Ltd.

The London Aerodrome silver medal will also be presented to all pilots (except prize-winners) completing the course, and the London Aerodrome bronze souvenir medal to all pilots who started but did not finish.

Allied Air Service Committee Under League of Nations Urged

London, July 13.—The practical co-operation between Great Britain, America and France by the formation of an allied aviation committee of the League of Nations is now vigorously advocated. The flight of the R-34 airship to America and her return and the enthusiastic reception accorded her on the other side by Americans again bring this matter into prominence.

It would be a sound policy, it is contended, to invite America's co-operation in the necessary organization and experiments to make trans-Atlantic flights commercially profitable. Much meteorological information is still required and many costly experiments in the construction, handling, loading, embarking and mooring are absolutely essential before the general public can be invited to accept the commercial airship as a regular means of transportation between Europe and America. The committee must be composed of practical men and not theorists, and influence should play no part in the selection of its members.

In addition to the work on the trans-Atlantic airships it would, of course, cover the whole field of aeronautical experiment and research by allocating various practical work to the air services of the respective countries represented. So far as Great Britain is concerned the initial step is essential before the formation of a committee, namely, the transfer of airships from the Admiralty to the Air Ministry.

Baroness De La Roche, Altitude Record Holder, Killed

Paris.—Baroness De La Roche, the famous French aviatrix, who holds the world's altitude record for women, was killed in an accident at the Crotoy Aerodrome. The Baroness received her pilots' license in 1910 and was the first woman to fly over Paris.

Vickers Trans-Atlantic Plane at Amsterdam

At the Air Exhibition at Amsterdam the Vickers-Rolls aeroplane in which Sir John Alcock and Sir Whitten Brown made their crossing is to be on view. During the exhibition an aerial service, which is to be maintained afterwards, between Paris and Amsterdam, should do much to keep interest alive in the show.

Swiss Flier First Across Alps in a Hydroaeroplane

Geneva.—The Alps were crossed for the first time by a hydro-aeroplane on July 12. Taddioli, a Swiss aviator, left Sesto Calende, Italy, at 9:30 o'clock and arrived at Geneva two hours later.

The aviator crossed the Simplon and flew over the valley of the Rhine and Lake Geneva.

D'Annunzio Offered Direction of Civilian Aviation in Italy

Rome.—The Italian Government has offered Gabriele D'Annunzio the post of Director-General of Civilian Aviation. D'Annunzio held a commission of Lieutenant Colonel in the Italian air service during the war and engaged in many bombing expeditions, including the raid on Vienna.

Albert Vickers, Aeroplane Constructor, Dies

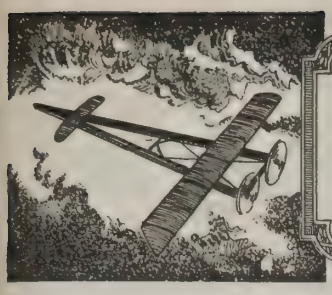
London.—Albert Vickers died at Eastbourne on July 12. Albert Vickers was formerly chairman of Vickers, Ltd., one of England's greatest manufacturers of steel products and also of aeroplanes.

Mr. Vickers was active in sports, taking particular interest in motor-boat racing, shooting and fishing. He was born September 16, 1838. His first wife was Miss Helen Gage of Boston.

He had been decorated with the Order of the Rising Sun of Japan and was made a Knight of the Grand Cross of the Order of Naval Merit of Spain.

Aircraft Equipment of French Naval Aviation Service

From a statement issued by the French authorities one notes that on October 1, 1918, the French Navy possessed 870 avions or hydravions, 59 airships, and 198 observation balloons, divided up as follows:



Sector	Avions or Hydravions.	Dirig.	Balloons.
Dunkirk-Cherbourg	168	21	22
Brittany	104	11	39
Loire-Bidassoa	74	7	21
Mediterranean (French coast)	110	4	41
Corsica	38	2	0
Portugal	16	0	0
Algeria-Tunis	176	11	31
Morocco-Senegal	44	0	0
Corfu	54	3	12
Ægean Sea	86	0	32
	870	59	198

Lieut. Cortinez Holds Altitude Record for South America

When the news first came to Europe recently that Lieut. Cortinez of the 1st Aviation Company of the Chilean Army had successfully flown across the Andes and back, it was not then realized that during this remarkable flight he had also established a height record for South America. For many years the height of 6250 metres recorded by the late Mr. Jorge Newbery, who lost his life in an essay to fly across the Andes, had been unchallenged. This year, however, Lieut. Parodi of the Argentine Army, attained to 6,480 metres on a Nieuport plane which was eclipsed by Lieut. Cortinez within a few days on crossing the Andes on a "Bristol" monoplane at an altitude of 6.500 metres.

Interior view of a Grahame-White passenger-carrying plane. The comfortable glass-enclosed cabin shuts out the roar of the engines

ELEMENTARY AERONAUTICS and MODEL NOTES

By John F. McMahon

Interesting Model Motors Used by English Model Flyers

Experimenting with models driven by electricity has never been attempted in this country to the knowledge of the writer. The only one to have experimented in this respect with any degree of satisfaction was Mr. H. R. Kerruish, an English model flyer who experimented with a model driven by an electric motor and carrying its own batteries. It weighs inclusive 9½ ozs. It had an area of 3½ sq. ft. The thrust (static) given is 2 oz., which is just sufficient to fly it, leaving hardly any reserve of power. The chief dimensions are: Span, 4 ft. 6 ins.; chord, 9 ins.; overall length, 2 ft. 11 ins. Elevator, span 18 ins., chord 4 ins. The propeller, 14 ins. in diameter and 10 ins. pitch. The complete weight of the plant is 5.5 ozs., and of the model, 4 ozs. It is very lightly built, but nevertheless is quite strong. It flies at 7:15 m.p.h. in a dead calm, but will not fly in any wind. The power plant is made up of a common tri-motor (tripolar-motor?) specially wound and carefully lightened, driven by six small cells constructed somewhat on the lines of the Delarue silver chloride cell, but embodying certain alternations which are known only to Mr. Kerruish. The thrust of 2 ozs. mentioned above is given off by the plant for a period about one and a half minutes. He cut down weight in every possible way, carpet thread soaked in glue for bracing is used instead of wire, and the planes are covered with the lightest chiffon doped with the thinnest solution sufficient for coherency. The model has flown quite well in suitable weather. The model was given its initial flight in the road opposite the inventor's house after dark, when little traffic was about, enough light to do so being afforded by the gas lamps. The model was started off in the middle of the road and the inventor keeping up with it by running, which was possible owing to its slow speed. As it has such a small reserve of power, it only rose about 4 ft. high, but kept fairly consistently at that height, so that it was possible to keep it going in the direction desired by lightly pushing the front to one side or the other. On one occasion the model was steered down the road in this manner for a distance of 152 yards, the flight then only finishing owing to a connection working loose.

Another form of motor is the CO_2 type, which is one getting its power from carbon dioxide gas.

Carbon dioxide gas in a liquid form is a well-known commercial product in England, stored in steel cylinders. At a pressure of some 35 atmospheres this gas condenses to a liquid at 0° C., or it may be liquefied at ordinary atmospheric pressure by a temperature of —78° C. The liquefaction of the gas can be effected either by evolving it in a strong closed vessel, so that it is condensed by its own pressure, or by pumping the gas by means of an ordinary forcing pump into a strong wrought-iron or steel receiver, kept during the process at a temperature of 0°. As soon as the volume of gas pumped in amounts to about thirty-seven times the volume of the receiver, each stroke of the pump produces a further condensation of the gas which is pumped in, and the vessel is easily filled with liquid CO_2, which is colorless and transparent. On being allowed to escape into the air, more especially if it emerges through a fine nozzle attached to the vessel, part of the liquid at once evaporates and assumes the gaseous state, so much heat being thereby lost that the remainder has no longer the necessary heat to maintain it in a liquid state. It therefore promptly freezes, thus producing a white snow-like mass (known popularly as carbonic acid snow), which evaporates comparatively slowly.

Liquefied CO_2 in expanding produces an enormous pressure which can be readily used in a motor provided that the freezing difficulty just referred to can be successfully overcome; it has this advantage over compressed air, that for the same quantity of gas the pressure on the reservoir is much less, which removes the likelihood of an explosion—giving either a reduced weight or a greater factor of safety. One peculiarity of the liquefied form of the gas is that under the application of heat the liquid form expands more than the gaseous —being an exception to the rule that liquids expand by heat less than gases.

In the Cetonia CO_2 motor (by term motor we mean complete plant) the freezing difficulty is overcome by using a cylinder filled with water at a temperature of about 90° C.; through this cylinder (or hot water bottle) runs a network of tubing into which the liquid CO_2 is passed direct, immersed as already stated in nearly boiling water. Now since CO_2 cannot remain liquid at a temperature above 31° C., its critical point, it immediately turns itself into a gas, and freezing is absolutely prevented by the specific heat of the water, which is very high.

Smallest Model of Curtiss JN-4

What is probably the smallest model to be built of the Curtiss training plane is less than 8" in span, and in spite of its small size all the parts have been accurately made. The struts are less than an inch in length, and yet they are tapered and streamlined to true section. The propeller is 1⅜" in diameter, and it has been carved with an accuracy unusual even in larger models. The model was made by G. Francis from plans and a description which appeared in the April 23, 1917, issue of Aerial Age.

The general dimensions of this machine are as follows:

Span, upper plane	7¾"
Span, lower plane	6"
Wing chord	⅞"
Gap between planes	⅞"
Stagger	3/16"
Length of machine overall	4¾"
Height of machine overall	1½"

The upper plane is made in three sections, and the lower plane is composed of two sections. The planes have an Eiffel 32 wing curve. Interplane struts between wings are placed as follows; there are 2 pairs of struts above the fuselage holding the center section plane, from these the intermediate struts are spaced 1⅛", and from these the outer struts are spaced 1¼". This leaves an overhang of 1¼". Both upper and lower planes have a slight dihedral.

The fuselage is ⅜" wide and ⅞" deep. The forward part of the fuselage is covered with sheet aluminum. The landing wheels are ⅜" in diameter, and they are spaced 15/16" apart. The elevator has a span of 2 13/16". Stabilizer is ⅝" wide, and elevators are ½" wide. The rudder is ⅞" in overall height and 9/16" wide. The triangular fin is ½" high and ½" wide.

All the finish is made to resemble that of the large machine. The wings are champagne color, the top of the fuselage from the pilot's seat forward as well as the cowling around the engine is khaki color; the tail surfaces and fuselage are the same color as the wings. The propeller is made of walnut finished in natural color and coated with spar varnish. Interplane struts, landing gear and tail skids are of spruce, shellaced and varnished.

Owing to the smallness of the machine, the control surfaces are not movable, but all have the appearance of being hinged. Grey silk thread is used to resemble wiring between wings and the control cables.

This model of the JN-4 is only 4¾" long. The wing span is 7¾"

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

R. Stanley Edwards in *Flying* on Aeronautic Slang

(*Continued from page* 902)

Ground-Louse ..... School machine not intended to leave the ground.

Penguin ..... A school machine which can only just leave the ground.

Kiwi .. .. Equipment officer R.F.C. without flying duties.

Shemu ..... Female personnel R.F.C.

Goldfish ... . Chips of bearing metal found inside the crankcase of a worn aeroplane.

Aerial Torpedoes..... A purely imaginary missile, which actually does not exist. Long, torpedo-shaped bombs originated the term, but they are quite different from the aerial torpedo, which no one has yet succeeded in inventing successfuly.

Canary Bird. ..... The albatross distinction mark worn by R.N.A.S. men.

Terms and Slang peculiar to the R.N.A.S

Quirk ..... A probationer, a "greenhorn," a young subaltern new to the Service. Formerly a "quirk" was a derisive term for a "school bus" or aeroplane in which learners were taught to drive.

Blimp ..... A "S.S." or scout submarine airship (small two-seater).

Canary Bird..... The albatross distinction mark worn by R.N.A.S. men.

Terms and Slang peculiar to the R.F.C.

Arp ..... Aeroplane repair park.

Hun ..... A R.F.C. "quirk"—a probationary sub, in the R.F.C., so-called because of the damage he can do to the machines and personnel with which he comes in contact.

Shemu ..... Female personnel R.F.C.

Kiwi ..... Equipment officer R.F.C. without flying duties.

Rumpety ..... School machines of the Farman type.

The following are slang terms used by soldiers throughout the Army and also among others by those in the Flying Service. Most of them belong to the men, and are not used by the officers:—

Slang	Meaning
Bob-Tack	Stuff to clean buttons.
A Yop or Yob.....	One who is easily fooled.
Vamping	Eating heartily.
To be Weighed Off.....	To be punished for an offense.
Tin-Opener	Bayonet.
To Go on the Tack....	To take the pledge.
To Swing the Lead.....	To tell a tall story.

Square Bit.....Best girl.

Slingers .....A meal of bread and tea.

A Scrounger.....A man who always gets what he wants for himself.

Rooty .....Bread.

Quarter-Bloke .....Quartermaster.

Pukka .....O.K.

Poultice-Wallahs .....R.A.M.C. men.

To Muck In.....To share.

Muckin .....Butter.

Baggie .....Sailor.

To Post his Number...To be reported for an offence.

Jankers .....Defaulters' drill.

High Jump.....To answer a summons of breaking regulations.

A Gravel Crusher.....An infantryman.

Get your Number; Dry; Get Under your Blanco-pot ..... Don't talk rot about things you don't understand.

How the New York Aerial Police picks them up, according to *Air Scout's* artist

(*Continued from page* 930)

vided on the outside of the hull for gaining access to the compartments.

This type of flying boat is purely a sport machine designed for pleasure flying. The complete enclosure of the passengers makes it unnecessary for them to don special clothing, as they are fully protected from wind and spray.

The upper plane has a span of 48′-4″; lower plane has a span of 27′-4″; chord 6′-3″ stagger 12″; gap between planes 6′-6″. Weight of machine empty, 2,000 pounds; weight fully loaded, about 2,500 pounds.

The Bellanca 35 H.P. Biplane

One of the smallest successful sport planes is the Bellanca 35 H.P. Biplane which weighs only 400 pounds. It is a two-seater but the forward cockpit can be covered over and machine made to appear like a single-seater. The machine can be used for carrying light express or mail for it has a useful load of 375 pounds.

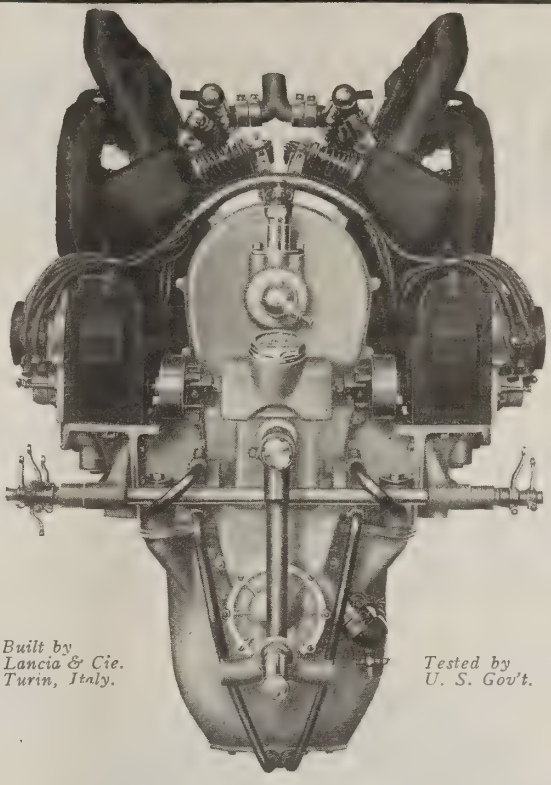
The upper plane has a span of 26′ and the lower plane has a span of 20′-6″. Chord of upper plane 4′ and of lower plane 2′-4″.

Total wing area, 150 square feet. Length overall 17′-7″. The maximum speed light is 85 M.P.H. and the minimum speed is 34 M.P.H. It can climb at a rate of 820 feet per minute. An actual test was made of its gliding ability in which it was shown that from an altitude of 4,600 feet, a glide of 10 miles was made and the descent required 8 minutes and 5 seconds time. An air-cooled, 3-cylinder, Anzani "Y" type engine is used, weighing 325 pounds.

The Lawson "C-1" Aerial Transport

The Lawson Aerial Transport Type C-1 was designed to carry 26 passengers. It is the first of its kind to be built in America and is probably the forerunner of several designs of the same type which will find an important place in the future of commercial aeronautics. The fuselage is entirely enclosed so that the passengers can enjoy the same comfort and security as found in the most up-to-date methods of transportation. Special mufflers are provided which reduce the usual roar of the engines. When it is desired to carry freight, the seats can be removed. Besides passenger carrying, machines of this kind can be used for express and mail delivery, or news distribution, aerial touring, and exploring. It has a normal fuel duration of 5 hours and its normal speed is 105 M.P.H.

Both planes have a span of 85′ and a chord of 9′-6″; gap between planes 9′-3″; overall length, 47′-7″; overall height 14′.



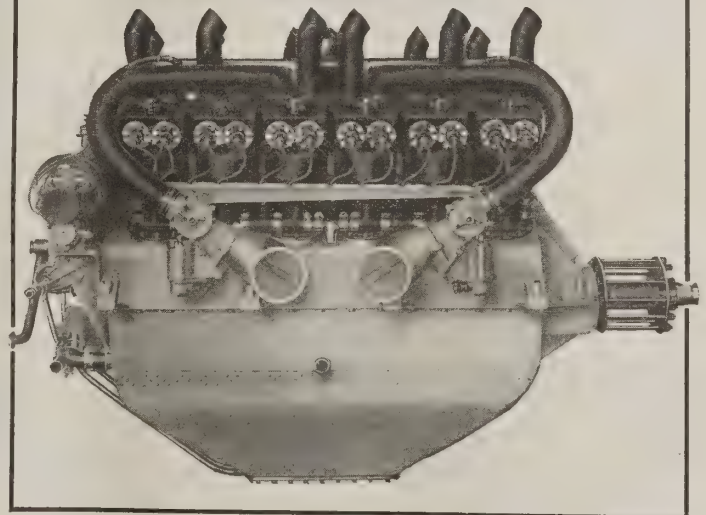
Fully loaded the machine weighs 12,000 pounds. In ten minutes it ascends to an altitude of 4,000 feet with a full load. The service ceiling is 15,000 feet and the gliding angle 1 to 8.

Two 12 cylinder 400 H.P. Liberty engines are completely enclosed in nacelles with radiators on their forward ends and propellers in pusher position. Propellers are 10′ in diameter and revolve opposite one another. Every effort has been made to increase the safety factor on all parts of the machine, and the provision of ample control surfaces makes the machine sensitive to control.

Thomas-Morse "S-7" Two-seater

The side-by-side seating arrangement of the Thomas-Morse S-7 makes it an ideal machine for passenger carrying and for ordinary pleasure uses. The passengers' compartment is upholstered and finished in accordance with best aeronautical practice, and first consideration has been given the problem of comfort and ease of maintenance. This is the first machine of the side-by-side type to employ an air cooled rotary engine. The side-by-side arrangement does not add to the width of the body because at the cockpit the body is no wider than at the cowling surrounding the engine.

Both wings have a span of 32′; length overall, 21′-6; height, 9′-0″. Fully loaded the weight is 1,480 pounds. The lifting surface including ailerons is 322 square feet, and the load per square foot is 4.6 pounds. An 80 H.P. Le Rhone air cooled rotary engine is used. The fuel capacity is 20 gallons, which is sufficient for a 2½ hour flight, and the oil capacity is 4 gallons, sufficient for 3 hours. The high speed is 90 M.P.H., and the low speed 40 M.P.H. In the first ten minutes the S-7 can climb to 6,700 feet.



Built by Lancia & Cie. Turin, Italy.

Tested by U. S. Gov't.

LANCIA AVIATION MOTOR
FOR SALE

This motor has been run only 10 hours in a test for the U. S. Government at McCook Field. The test showed it developed 320 h.p. at 1,380 r.p.m. and weighs 740 lbs. Surprisingly low gas consumption. It is unquestionably one of the most efficient 12 cylinder aviation type motors in the world. A number of spare parts is included with the motor, such as a complete set of extra cylinders, pistons, water pumps, etc. Can be inspected any time.

W. Evitt, Dudley Miller Outcalt, George Lyon Nicol, Walter B. Dudley, William V. Marshall, Edgar A. Rogers and John Humphrey Small, Jr.

To be captains, Air Service: Jesse A. Johnson, Paul Earl Palmer, Clarence Roy Sigwalt, Joseph W. Hughes, George W. Clayton, George Arnold, Clarence A. Phillips, Ralph Estes Whittle, Lewis A. DeVore, John Francis Bligh, Burt Alfred Skellan, John K. Hampton, Colin Alfred Campbell, William Andrew Gray, George H. Bryan, Russell Bonner Kirby, Jr., Henry T. Hale, Harold Von Thaden, Kenneth MacKenzie, George Wilson Dodds, William Millard Hamilton, Clarence Berry Mitchell, Richard Howard Randall, Charles L. Hayward, John Clifford Bryan, Ralph E. Spake, Vincent K. Butler, Jr., Lesley B. Simpson, Jess Fry, Jr., Oris Petty Embleton, Ralph H. Mosher, Edwin Moseley Sampson, Hilton W. Long, Gerliss C. Moseley, William H. Y. Hackett, Frank A. Ayer, William Lentz and John James Elliott.

To be majors, Air Service: Warren P. Munsell, Frederick W. Zinn, Fred W. Sizer, Arcemus Carter, Andrew B. Hawkins, Robert George Bloedel, Henry Capron White, Veon Irwin Moncrieff, Thomas J. Leary, Harry O. Payne, Gustav Vordtriede, Vardra Magbee Hallman, Jr., Charles C. Merz, William A. Dickema and John Gordon Rankin.

To be lieutenant colonel, Air Service: Frederick J. Ostermann, John Hamilton Jouett and William B. Wynn.

To be colonel, Air Service: Olan C. Aleshire.

The following-named officers will proceed to Plattsburg Barracks, N. Y., and report in person to the commanding officer, United States Army General Hospital No. 30, that place, for duty: Franklin E. Allen, Ralph D. McLaughlin and John Sunderland, Jr.

The following-named second lieutenants, Air Service (Aeronautics), will proceed from Washington, D. C., to Souther Field, Americus, Ga., and report in person to the commanding officer for duty: Samuel W. Dunford and Paul G. Peik.

The following-named second lieutenants, Air Service (Aeronautics), will proceed from Carlstrom Field, Arcadia, Fla., to Souther Field, Americus, Ga., and report in person to the commanding officer for duty: Robert T. Cronau and John A. Wyatt.

The following-named officers will proceed to Washington, D. C., and report in person to the Director of Purchase, Storage and Traffic for duty with the Director of Finance: Fred J. White and Bernard F. Bockenfeld.

Capt. John A. Macready will proceed by aeroplane to Bolling Field, Anacostia, D. C., and upon completion of the duty enjoined, will return by rail to his proper station, Dayton, Ohio.

Maj. Dean Smith will proceed by aeroplane to Bolling Field, Anacostia, D. C., and upon the completion of this duty will return by rail to his proper station, Dayton, Ohio.

Second Lieut. Herbert E. Metcalf will proceed to San Francisco, Cal., and report in person to the General Superintendent Army Transport Service for transportation to Fore Island, Pearl Harbor, Honolulu, Hawaii, by the first available transport. Upon arrival in Hawaii he will report in person to the commanding general Hawaiian Department for duty with the 6th Aero Squadron. Lieut. Metcalf will apply to the Chief of Transportation, Munitions Building, Washington, D. C., for accommodations for so much of the journey as requires water transportation.

The following-named officers, Air Service, will proceed to Fort Sam Houston, Tex., and report in person to the commanding general Southern Department for assignment to duty: Joseph H. McCulloch, Harold C. Block, Edgar A. Liebhouser, Philip Rozelle and Sidney L. Wheaton.

Christopher A. Reid will proceed to Montgomery, Ala., and report in person to the commanding officer aviation repair depot for duty.

First Lieut. Homer Rogers will report in person to the Director of Purchase, Storage and Traffic, Washington, D. C., for duty with the engineering and standardization branch.

First Lieut. Frederic Hamilton Thorne will proceed to Mineola, Long Island, N. Y., and will report by letter to the Director of Air Service, Washington, D. C.

First Lieut. Henry W. Isbell will proceed to Ellington Field, Houston, Tex.

Capt. Charles H. McDonald will report in person without delay to the Director of Air Service, War Department, Washington, D. C., for duty as legal adviser to and as a member of the Air Service Claims Board.

Second Lieut. James Pratt Hodges will proceed to Langley Field, Hampton, Va.

First Lieut. James Henry Sullivan will proceed to Washington, D. C., and report in person to the Director of Air Service, for duty.

First Lieut. Ernest P. Haley will proceed to Fayetteville, N. C., and report in person to the commanding officer Pope Field, Camp Bragg, for duty.

Second Lieut. Matthew E. Finn will proceed to Carlisle, Pa., to the commanding officer United States Army General Hospital No. 31 for duty.

First Lieut. Hiram E. Wilson is assigned to duty with the Committee on Training Camp Activities, and will report in person to the commanding officer March Field, Cal., for assignment to duty as athletic officer.

Leave of absence for 10 days is granted First Lieut. Carl E. Royer, Air Service (Aeronautics).

Second Lieut. Percy H. Heron is transferred to Walter Reed General Hospital, Washington, D. C., and will report in person to the commanding officer that hospital for further observation and treatment.

Second Lieut. Theodore J. Lindorff will proceed to Washington, D. C., and report in person to the Director of Air Service for duty.

Second Lieut. Thomas A. Stratton will proceed to Hazelhurst Field, Mineola, Long Island, N. Y., and report to the commanding officer at that camp for discharge.

First Lieut. Harry C. Colburn is announced as being on duty requiring him to participate regularly and frequently in aerial flights from December 2, 1917, to May 11, 1918.

Second Lieut. Henry G. Woodward will proceed to Bolling Field, Anacostia, D. C.

First Lieut. Charles C. Cook will proceed to Washington, D. C., and report in person to the Director of Air Service for duty.

Second Lieut. John Henry Gardner will proceed to Souther Field, Americus, Ga.

Second Lieut. Kenneth B. Wolfe will proceed to Souther Field, Americus, Ga.

Second Lieut. Arthur Anthony Sego, Aviation Section, Signal Corps, is announced as on duty requiring him to participate regularly and frequently in aerial flights from August 26, 1918, to September 12, 1918.

Capt. Edward W. Rucker, Jr., will proceed to Boston, Mass., and report in person to the commanding general Northeastern Department for duty in the office of the department Air Service officer.

Second Lieut. Harold R. Wells will proceed to Fort Omaha, Nebr., and report in person to the commanding officer Army Balloon School for duty.

Some Notes On Engine Running

(*Continued from page* 933)

Sudden failure to fire (all cylinders)	Complete failure of fuel supply	Fuel pipe broken. Fuel tap closed by vibration.
	Complete failure of ignition	Connection to distributor broken. Distributor brush broken. Lead from magneto to switch in contact with "earth." Complete failure of magneto.
"Popping" in carbureter	Weak mixture	Air leaks in induction pipes. Carbureter jet too small. Failure of gasoline supply due to choked jet. Gasoline tap partly closed by vibration. Insufficient pressure in petrol tank.
	Water in fuel system	Condensation or water in gasoline cans (gasoline should be filtered through chamois leather.)
	Inlet valve sticking	Dirty or damaged valve stem. (*See above.*)
	Exhaust valve sticking	*See above.* In stationary engines, this will result in contact between hot exhaust gases and incoming mixture.
	Weak valve spring	(Renew.)
	Incorrect timing	Too much overlap.
Overheating	Weak mixture	As above.
	Failure of lubrication	Leaks in oil system. Choked pipes or filters. Oil too hot. Insufficient oil. Oil pump failure.
	Spark too far retarded	
	Failure of water circulation	Leaks in water system. (Inspect all joints.) Piping, jackets or pump clogged with sediment and scale. Failure of water pump. (Impeller loose on spindle—broken impeller.)
	Loss of compression	Worn or damaged piston rings. Worn or damaged obturator rings. Look for "blueing.") renew.) Leaky plugs. (Fit new washers or renew.) Gudgeon pin loose resulting in scored cylinder.
Knocking	Pre-ignition	Overheating (as above) causing particles of carbon deposit, spark plug points, or exhaust valves to become hot enough to ignite the charge during compression. In the absence of actual incandescence, acute general overheating may result in spontaneous ignition.
	Spark too far advanced	
Vibration	Engine out of balance	In rotary engines, a new cylinder incorrectly fitted or of incorrect weight. In stationary engines a new piston of incorrect weight. Bent crankshaft.
	Part of engine or engine fittings loose	
	Engine mounting faulty	
	Propeller out of balance	
	Propeller or propeller boss loose	
Engine continues to fire after switch has been put in "off" position	Self ignition	Overheating. (*See pre-ignition.*)
	Broken switch circuit	Defective switch, bad "earth" connection or broken leads to switch.
Smoky Exhaust	Overlubrication of cylinders (bluish grey smoke)	
	Mixture too strong (black smoke)	Carbureter flooding due to punctured float, worn or damaged needle, or dirt on valve seating. Jet too large. Air intake gauze choked. Air pressure excessive owing to failure of relief valve.

Flexibility and versatility, resulting from combined stability and strength, commend Boeing Seaplanes to professional pilots and to sportsmen of the air. Ability to stand up under the most gruelling tests and day-in, day-out service, the result of perfected materials and refined craftsmanship, assure safety to the most daring. The greatest spruce-producing country in the world, surrounding the place of Boeing manufacture, gives its best wood to Boeing aircraft. Boeing Seaplanes combine symmetric and assymetric stability to a degree never hitherto attained. May we address you a personal letter?

Enemy Tried to Get American Radio Secrets

Washington.—The War Department made public recently a captured German document showing the importance the enemy attached to salvaging our aeroplane wireless apparatus of the "continuous or undamped wave type." The document is also looked upon as indicating that the Allies had progressed further than the Germans in the radio equipment. It reads in translation:

"XIII. (Wurtemburg) Army Corps, H. Q., Corps Headquarters, 5-6, 1918. Routine Order No. 30.

1. (1s) Captured aviation W. T. fittings.

"The enemy has found it possible to use wireless installations for undamped waves in his aeroplanes. So far few fittings of this type of apparatus have been captured by us, and in order to enable us to make use of this as soon as possible and also so as to save millions, which would have to be spent in experiments, it is everyone's duty to see that all W. T. fittings from captured aeroplanes are salved as completely as possible. Even the smallest pieces will be collected as a tyro cannot recognize the value and importance of small parts to the expert.

"W. T. fittings which have been salved will be forwarded to the nearest aircraft unit, which is responsible that they are sent on immediately to the commander of aviation.

"In view of the importance of these fittings for our own wireless telegraphy, sums paid for salvage will be high."

The surprising efficiency and success of Allied radio equipment caused strenuous efforts on the part of the Germans to capture samples of our equipment.

Seventy-fourth Aero Squadron on Coast Defense Duty

Washington, D. C.—According to a statement issued by the Director of the Air Service, the 74th Aero Squadron, organized at Langley Field, Va., to utilize 20 De Haviland aeroplanes in connection with the coast defense, will carry on aerial adjustment of artillery fire for the coast artillery batteries stationed at Fort Monroe, and will adjust on floating targets as far as 20 miles out. These planes have been turned over to the squadron and will be assembled by Air Service recruits.

The squadron will maintain regular practice surveillance patrols over this section of the coast, when operating with the artillery, a system of finding the target and destroying immediately by the rapid adjustment of artillery fire by wireless.

The 74th Aero Squadron is commanded by Capt. Cleaton Reynolds, who commanded the 104th Aero Squadron in San Mihiel and the Argonne offensive.

Operations will be directed by Capt. Frazier Hale, who was the operations officer for the Air Service of the Fifth Army Corps at San Mihiel and the Argonne.

Liaisqn will be conducted by Capt. H. M. Gallop, who also commanded an active service squadron in France.

As it is proposed to establish a brigade of Railway Artillery near Fort Monroe, this squadron will also operate with this extra heavy artillery.

Souther Field Secures Recruits By Clever Campaign

Souther Field, Va.—In order to create interest in the Air Service on the part of enlisted men, Lieut. Floyd A. Wilson, personnel adjutant and publicity officer, has issued an application to all enlisted men at the field, calling for the following information: Name in full, name of daily paper at his home town, and whether he desired a flight.

If a cross-country is planned to any such town, the enlisted man is taken as passenger to his home town, the local newspaper is wired and a reception prepared for the man's visit, thereby creating sufficient interest to cause a 32 per cent increase in the enlistments at Souther Field.

Foreign Service Roster

In completing the War Department foreign service roster, beginning with January 1, 1917, and for future computations, service in Alaska, China, Hawaii, Mexico (Punitive Expedition 1916 and 1917), Panama, Philippine Islands, service with Porto Rico Regiment of Infantry outside limits of United States, service overseas with all American Expeditionary Forces and service when attached to foreign armies in actual campaigns, will be counted as foreign service.

Foreign service will be counted from date of departure from continental limits of the United States of America to date of return, both dates included. It is directed that all officers of the Army be guided by the above, but that this is not to be construed as in any way modifying the foreign service roster in effect up to end, including December 31, 1916.

VOL. IX NEW YORK, AUGUST 4, 1919 NO. 21

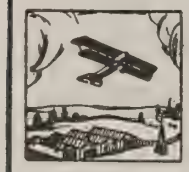
CURTISS COMPANY PURCHASES ATLANTIC CITY AIRPORT

FINDING that the organization of the extensive pioneer aeroplane tours, and similar pioneer constructive activities need his entire attention, Mr. Henry Woodhouse, the founder and owner of the Atlantic City Airport, has accepted the offer of the Curtiss Aeroplane and Motor Corporation and has sold the Airport to the Curtiss Company. As the first Airport and Municipal Flying Field, the Atlantic City Airport has achieved world prominence during the past four months since Mr. Woodhouse created and established it. At the time there was no civilian flying and it was generally stated that aviation activities could not be started this year. And it was feared that by next year public interest would die out and the aircraft industry would die of starvation. Mr. Woodhouse was almost alone in his belief that civilian aviation activities would begin as soon as a flying field was made available and events were organized to enable those interested in flying to participate actively. He presented the idea to many people and organizations and was called visionary. Then he decided to prove the soundness of his plan at his own expense. In two months he organized the Aeronautic Convention and Aerial Contests held at Atlantic City in May and established the Atlantic City Airport. He also organized the extensive series of important scientific and practical aerial tests and demonstrations conducted at the Airport during the past two months and started an entirely new epoch in aeronautics.

So important were these demonstrations that thirty countries sent their representatives to witness them and the Airport has been the meeting place of international aeronautic experts ever since.

The Airport became the mecca of aviators, civilian and military. They arrive at the Airport daily from different parts of the country, put up overnight or stay a few days and participate in tests and demonstrations and then proceed on.

The first aeroplanes bought by civilians since the war, with two exceptions, were bought for the Atlantic City activities, for passenger carrying, intercollegiate contests and pleasure flying. Today these are not less than five hundred individual aeroplane owners and the manufacturers cannot fill the orders fast enough. It is estimated that two thousand planes could be sold this summer if the manufacturers could deliver them. The Curtiss Company has sold 132 one hundred H. P. biplanes of the type known as "Orioles," which made its initial flight from Mineola to Atlantic City on May first in a storm, for the opening-day celebrations of the Second Pan-American Aeronautic Convention and Exposition, and was the first plane to arrive at the Airport. It carried Mr. Victor Hugo Barranco, the representative of President Menocal of Cuba, who brought a message from the latter to be read at the Convention.



Many of the owners of these aeroplanes have signified their intention to participate in the aeroplane tours which are to start at the end of August or in September, and are to extend south as cold weather comes.

To begin with, the tours will be divided into four classes, as follows: (1) One-day tours for people who can only spend one day a week; (2) week-end tours, which will last from Friday to Sunday or Monday, for people who can only spend their week-end; (3) "Vacation Week Tours," which will last one week for people who wish to spend a week of their vacation in aerial touring; (4) three thousand mile tours, which will last ten days, for the people who wish to spend two weeks of their vacation in aerial touring. One of the aims of the tours will be to open airways for air travel, and establish supply stations throughout the country for air travellers.

The average travel for one day in these aerial tours will be 250 miles, which is less than four hours in the air, so as to afford plenty of time each day for aerial tourists to "take in" other diversions, such as tennis, golf, swimming, motoring, riding, etc., wherever they stop. Expert mechanics, spare parts, fuel and supplies will be provided at the stopping places, where necessary repairs will be made, tanks filled and aeroplanes attended to at the lowest possible charges.

Every effort will be made to create a market for the surplus Army and Navy aeroplanes, motors, accessories, and aeronautic materials. The Atlantic City Airport, the world's first Airport, is located in the heart of Atlantic City, where approximately 15,000,000 people come each year from every part of the world. It is the first municipal flying field in the world and the official flying field of the Aero Club of America, the Aerial League of America, the Pan-American Aeronautic Federation, the Atlantic City Aero Club, and the National Aerial Coast Patrol Commission. It is the center of intercollegiate aerial contests, aerial shooting contests and scientific demonstrations and tests. It is the only place in the world affording facilities for land and water aeroplanes practically in the heart of the city. It is also the only flying field in the world having five and ten kilometer courses marked with regulation high towers as required by the International Aeronautic Federation for testing the speed of aircraft and for aircraft contests. The Airport is located in the heart of the city and has the riparian rights on the thoroughfare, which affords a fine location for hangars for seaplanes. It covers the entire section of Atlantic City which is known as Chelsea Heights, and has a frontage of 3,400 feet on Albany Avenue, with a frontage of 3,400 feet on South Boulevard. The entrance to the aviation field is only 2,000 feet from the Boardwalk and four minutes by automobile from the Atlantic City Railroad Station, with railroad siding within 300 feet of the Airport entrance and cranes for unloading aeroplanes and motors. It has a water main, and electric current and suitable police and fire protection. The value of the land of the Airport is set at over half a million dollars. The negotiations were conducted on behalf of the Curtiss Company by Mr. W. W. Mountain, Vice President and General Manager, and Mr. J. W. Forse, secretary of the Curtiss Company. It is understood that the Curtiss Company have plans for extensive activities to be conducted at the Airport, and a statement regarding the plans is to be issued by Mr. W. W. Mountain.

Mr. Woodhouse is to have the use of the Airport for the Aeroplane Tours, Intercollegiate Contests, Aerial Shooting Contests, and scientific tests and practical aerial demonstrations. Mr. Mountain has stated that one hundred thousand dollars will be spent to improve the Airport and make it "The World's Aeronautic Show Window."

The News of the Week

Curtiss Plane Breaks American Altitude Record

Mineola, L. I.—According to information from the Curtiss Engineering Company, the American altitude record was broken on July 25 by Roland Rohlfs, test pilot for the corporation, who in one of the new Curtiss "Wasps" reached a height of 31,100 feet. The record has not yet been homologated by the Aero Club authorities. This is 2,200 feet better than the record made last year by Major R. W. Schroeder, U. S. A., who in a British-built Bristol with a Hispano-Suiza motor attained an altitude of 28,900 feet. The French aviator Casale, in a Nieuport, is credited with an unofficial record of 33,100 feet.

The machine Rohlfs flew is a triplane designed and built as a pursuit machine for the United States army. It is equipped with the new 400-horsepower Curtiss motor and under government tests has attained a speed of 160 miles an hour.

Martin Bomber Starts on Flight Around Country

The Martin bomber, carrying a crew of five, commanded by Lieut. Col. R. S. Hartz, left the ground at Washington at 10 A. M., July 24, on the first leg of a flight of nearly 8,000 miles around the rim of the country.

The flight is the longest ever attempted by the Army Air Service, and will carry the machine through thirty-one States, over ninety-five cities, and cover long stretches of the Atlantic, Pacific, and Gulf Coasts, as well as the Canadian border.

Lieut. Col. Hartz was accompanied by Lieutenants Ernest E. Harmon and Lotha A. Smith as reserve pilots, and Sergeant John Harding, Jr., mechanic, and Jeremiah Tobias, master electrician. The big machine rose from Bolling Field, circled the White House in low flight then headed away on its course.

The general line to be followed will carry the machine in order to Duluth, Minn.; Seattle, Wash.; San Diego, Cal.; San Antonio, Texas; Miami, Fla., and back to Washington. The actual measured distance of the route is 7805 miles.

The time for the first lap of the journey from Washington to Mineola, a distance of 200 miles, was made in 145 minutes. Water and oil leak developed over Baltimore. Master Electrician Jeremiah Tobias walked out on the wing and fixed the same, photographs being taken of the work.

On July 25, the machine left Mineola at 8:25 A. M. and reached Augusta, Me., at 1:05 P. M., making a perfect landing on the State muster grounds.

Lieut. Col. R. S. Hartz, on July 26, resumed his flight in a Martin bombing plane around the rim of the United States, after four hours' delay on account of engine trouble.

The plane rose at 11:15 A. M. on what was intended to be a flight of 660 miles to Cleveland, Ohio. After being lost in the air for nearly three hours the army bombing plane landed at Upper Jay, near Lake Placid, burying its nose in the ground. The crew were badly shaken up but none was seriously injured. Lieut. Col. R. S. Hartz stated that the machine would be forced to remain at Upper Jay for at least two weeks to make necessary repairs. In hitting the ground one wheel, damaged in landing at Augusta, broke, swinging the machine completely around.

Bowman Increases Toronto Flight Prize

John McE. Bowman announced that he had increased the prize for the air race between New York and Toronto, and from Toronto to New York, from $5,000 to $10,000. Mr. Bowman offered the $5,000 prize some time ago. The race is to be in the week of August 25, at the time of the Canadian National Exposition.

Fishing from Seaplanes Saves Time

Atlantic City, N. J.—Earle L. Ovington, president of the Curtiss Flying Station at Atlantic City, and Mr. C. W. Forse, secretary of the Curtiss Aeroplane and Motor Co. of Buffalo, started off recently in a Curtiss "'Seagull" for the fishing banks, five miles off the coast here. In less than four minutes the folding anchor had been thrown overboard; in three minutes the first bite was reported; within eight minutes they had caught three fish; four minutes later they were back at the hangar. By boat more than an hour would have been consumed in going to and from the banks. If you value time, use an aeroplane.

Aeromarine Passenger Carrier Makes Speedy Atlantic City Trip

Atlantic City, N. J.—The New York-Atlantic City passenger carrying service, inaugurated by the Travellers' Company of New York City, carried two passengers and pilot from New York to Atlantic City and return between 1 and 7 P. M. The trip down was made in 150 minutes and the return in 78 minutes. The distance is 105 miles.

Those who had obtained booking for the first flight on the seaplane line were Mrs. John A. Hoagland, wife of a baking powder manufacturer, and her friend, Miss Ethel Hodges of Dallas, Tex. They were safely ensconced in wicker seats in the cabin de luxe, which is upholstered in brocaded satin.

In the pilot's seat was Robert W. Hewitt, formerly with the United States Naval Air Forces. The fare is $100 each way and each passenger is permitted to take thirty pounds of baggage. Baggage over that weight will be charged for at the rate of $1 a pound.

The boat, equipped with a 150-horsepower motor, is twenty-six feet long and has a wing spread of fifty feet. C. Nicholas Reinhardt is manager of the new line.

All aboard for Atlantic City on the Aeromarine aerial limousine. Mrs. John A. Hoagland and Miss Ethel Hodges were the first passengers from New York to the coast resort. They were safely piloted there and back by Robert W. Hewitt

Balloonists Meet at Worcester

Worcester.—The pilots interested in ballooning convened in Worcester recently and voted to make Worcester the central headquarters of the Eastern department of balloon aviation. Among those present were J. Walter Flagg, expert balloon pilot, and vice-president of the New England Aero Club; N. H. Arnold, balloon pilot and instructor for an army balloon school, who made several long-distance flights years ago; Lieutenant Joseph L. Batt, instructor at the Fort Omaha Balloon School during the war and in charge of the balloon house; Theodore E. Hedlund, ex-United States war service overseas aviator and president of the Massachusetts Aero Club of Service Aviators, and Ensign Lester P. Dodge, who saw service in the naval plane department.

The airmen voted to procure several balloons and it is hoped to begin flights September 1.

Commutes to Summer Home By Air

Vineyard Haven, Mass.—Week-end commuting by aeroplane received an impetus on July 25 with the completion of a New York-to-the-Vineyard flight by two wealthy summer residents, Melvin B. Fuller and Myron J. Brown, New York business men, and their pilot, C. D. Griffin. Leaving New York at 2:40 P. M. they landed at Oak Bluffs at 5:30 P. M. The flying time was 2 hours, 30 minutes. They made a stop at Cosey Beach, Conn.

Inspecting Balloon School Site at Camp Dix

Officers representing the Federal Balloon Commission are inspecting and mapping out the land in the vicinity of Lewistown, west of Camp Dix, N. J., which will be required for the proposed balloon school—the largest in the United States.

Aeroplane Helps Auto Racer to Victory

Detroit, Mich.—The Bearings Service Company of Detroit received an order from Tommy Milton, driver of the winning Duesenberg car at the Uniontown Races just 24 hours before the race. The front wheel was broken in a trial the day before the race, and a thorough search of Uniontown and Pittsburgh failed to unearth a bearing of the proper size. Train connections being impossible, the Universal Aeroplane Company was called on and a flight of 300 miles was made in 210 minutes, the remainder of the distance being completed by automobile. Repairs were made in time, and Milton and his Duesenberg won the race.

Mrs. H. L. Potter of Madison, Wisc., well known trapshooter and sportswoman, is the first of her sex to purchase an aeroplane for purely pleasure purposes

Ten Planes Fly to Albany

Albany, N. Y.—In command of a squadron of ten aeroplanes, Col. Archie Miller, on July 25, flew from Mineola to the State capitol, in order to deliver reports and recommendations concerning aerial activities for the information of the Governor. The Curtiss H made the trip in 85 minutes and the De Haviland in 70 minutes.

Mexico to Purchase Military Aeroplanes

Washington, D. C.—Ambassador Bonillas, of Mexico, in conference at the State Department on July 17 with Acting Secretary of State Polk and Henry P. Fletcher, American Ambassador to Mexico, renewed his request for permission to purchase aeroplanes and munitions in this country for his government. He said after the conference he believed the request would be granted.

Mr. Bonillas, who has just returned from a month's stay in Mexico City, reported on the progress being made to pacify Mexico.

First Woman Pleasure Flyer

Mrs. H. L. Potter, of Madison, Wis., has the distinction of being the first woman in the world to purchase an aeroplane for pleasure flying.

Ruth Law and Katherine Stinson have been flying for several seasons but they have taken up aviation as a commercial proposition.

Mrs. Potter purchased a Curtiss JN-4D from George W. Browne, Curtiss distributer for the Middle West, and she has been using it on shopping tours between Madison and Milwaukee and Chicago.

She is one of the best trap-shots in the country, attending all the tournaments in the West and she will use her plane as a means of transportation this summer.

Lt. Robert Connelly, formerly of the U. S. air service, has been engaged as pilot and will teach Mrs. Potter how to fly.

The twin-motored Loughead flying boat ready for service at Santa Barbara, California. It carries fuel for a 450 mile trip with ten passengers

Rockaway Plans Shaft to Mark NC-4 "Hop Off"

A meeting of the Rockaway Civic League took place at the Belle Harbor Yacht Club to form an organization to raise a fund to erect a monument to commemorate the flight of the NC-4 across the Atlantic.

T. Burke McGuire was elected chairman and tentative plans were formed for a national appeal for funds. It is proposed to place a shaft at the spot where the NC-4 "took off" at Rockaway Point.

Many Entries in New York-Toronto Flight

New York, N. Y.—A large number of aviators have signified their intention of entering the New York-Toronto contest. On the American side are Col. H. E. Hartney, United States commander of the Third Pursuit Group of fighting aeroplanes at the front; Lawrence A. Sperry, inventor of the aeroplane automatic gyro stabilizer; Capt. James S. Foote, Government instructor; Major William S. Schroeder, altitude record holder; Lieut. W. H. Murray, the English fighting pilot; Capt. George Traill, attached to the British Air Ministry in the United States; Capt. Paul Baer, the famous American ace, who was captured by the Germans after being shot down twice and who later made his escape in a German aeroplane; Roland Rolf, the crack Curtiss test pilot; Capt. Edward Green, an ace of the famous Lafayette Escadrille, composed of American fliers who joined the French air service before the war came our way; Edward Stinson, United States Government instructor and test pilot; H. C. Ferguson, famous American test pilot at the mammoth aviation center at Issoudin, France, during the great war; A. B. Gaines, Col. James G. Vincent, vice-president of the Packard Motor Car Company, who was one of the designers of the Liberty motor; Howard A. Rinehart, of the Dayton-Wright Aeroplane Company, famous as a test pilot for Orville Wright and holder of numerous cross-country records.

Among the Canadians who will enter the contest are Col. W. A. Bishop, V. C., D. S. O., and Col. Barker, V. C., both famous Canadian aces, together with Capt. William Younghusband and F. G. Ericson. Col. Barker has already been testing out a number of German Fokker fighting machines which were brought down intact at the front during the war. He had an arm shot off during an aerial battle with a squadron of Hun fliers. He has a record of bringing down thirty-six German machines. Col. Barker is to have the distinction of flying with the Prince of Wales to show the latter how the city of Toronto looks from an aerial viewpoint.

Dirigible Accident in Chicago

Chicago, Ill.—Eleven persons were killed and twenty-seven injured when an exhibition dirigible from a Chicago amusement park caught fire over the business district and plunged through the roof of the Illinois Trust and Savings Bank Building. After flying over the city for several hours, flames were seen to burst out through the top of the blimp's envelope. Four of the five occupants of the craft jumped with parachutes and two made safe landings, one being fatally injured in striking the ground, and the fourth being overtaken by the flaming craft and carried with it through the roof of the bank building. Instantly the entire building appeared to be in flames and the gasoline tanks were heard to explode. Nine of the bank personnel were killed as a result of the fire.

The cause of the accident has not been determined. It may be that the bag burst from the heat and sparks from the exhaust caused the fire to start. The manufacturers of the dirigible have agreed to pay all damage resulting from the accident.

Wed by Radio Telephone Aboard Aeroplane

Matrimony in the air was a feature at Speedway Park, Sheepshead Bay, on July 26, at the second Police Field Day, when Miss Milly K. Schaefer, daughter of Mrs. Katharine Schaefer, of Sea Gate, became the aeroplane bride of Lieutenant George H. Burgess, U. S. Air Service, flying at an altitude of 1,000 feet, with an assembly below of 200,000 spectators. The first real sky pilot married the couple through the use of the radio telephone.

The ceremony was conducted between two United States Army-Curtiss aeroplanes equipped with 150 horsepower motors. The prospective bride and bridegroom flew in one machine, while the minister and best man occupied the second plane.

The ceremony was performed by the Rev. Alexander Wouters, pastor of the Edgewood Reformed Church, Borough Park, Brooklyn. Lieutenant Eugene H. Barksdale, U. S. Air Service, acted as best man, and Miss Doris K. Schob, of Brooklyn, served as bridesmaid. The bride-elect had never been up in an aeroplane.

Oil Magnate Commutes from Denver to Tulsa in Oriole Plane

Buffalo, N. Y.—Mr. I. B. Humphreys, president of the Humphreys Petroleum Co., has purchased a Curtiss three-passenger Oriole biplane for use in traveling between his Denver home and his oil properties located near Tulsa, Okla. He is forced to make the trip several times a month and finds the journey very irksome, requiring thirty-six hours. His new means of travel will enable him to leave his home in the morning and return the same evening. He will return to Buffalo in August to secure a second Oriole which he will use in a passenger-carrying service over the mountains to Estes Park and Colorado Springs.

Two Ex-R.A.F. Officers Will Take Long Trip in Curtiss "Seagull"

The longest flight undertaken by civilian flyers in a flying boat since 1914 will start from New York early next month, when S. E. Parker and G. Talbot Willcox, former Majors in the Royal Air Force, will set out for New Orleans by the inland water route. They may continue their flight around the Gulf of Mexico to Panama and South America.

They will make the trip in a Curtiss "Seagull," equipped with wireless telephone and telegraph. Heading up the Hudson, they will stop at Peekskill, Newburgh, Poughkeepsie, Catskill and Albany. Thence they will fly to Troy, Schenectady, Stillwater, Saratoga Springs, Glens Falls, Lake George, Ticonderoga, Burlington, Plattsburg and Alburg. Their schedule calls for arrival on the St. Lawrence in September. Moving west, they will stop at Syracuse and Oswego, Ontario Beach and Buffalo. From Buffalo the boat will be shipped to Cincinnati, and the route will lie down the Ohio and Mississippi Rivers, arriving at New Orleans in time for the Mardi Gras.

Major Willcox flew in the Dardanelles campaign and Egypt during the war. Major Parker served in France in the 60th British Pursuit Squadron, to which Col. William Bishop, "ace of aces," was attached.

San Diego-San Francisco Flight at 135 Miles An Hour

San Francisco, Cal.—The remarkable time of 272½ minutes (speed 134.22 per hour) made by Lieut. J. W. Sharpnack, in a Liberty motored Le Pere, on July 24, for a distance of 610 miles on a non-stop trip from San Diego to San Francisco, carrying one passenger, has established a record for travel between San Diego and San Francisco. The motor, despite the strain of the flight, was in perfect mechanical condition upon its arrival.

Air Line Between New York and Bridgeport Planned

Bridgeport, Conn.—Bridgeport is ready for the establishment of an air freight and passenger line, as announced in New York by the National Air Service Corporation, which plans to operate an aerial transportation system between New York and Boston with stops in this city and New London. Several months ago the Chamber of Commerce appointed an aviation committee, headed by former army officers. A landing field was selected. This field will be used as a landing place for the air line, according to announcement made here. Two biplanes will be used by the service.

Boeing Completes Navy Order for HS-2L Boats

Seattle, Wash.—The Boeing Aeroplane Co. has completed its contract with the Navy Department for Liberty motored HS-2L flying boats. The order originally called for fifty of these craft, but upon the signing of the armistice, the order was reduced to twenty-five.

Pacific Aviation Company Has Carried 500 Passengers

The Pacific Aviation Company of San Francisco, operating two Glenn Martin type TT biplanes, has already carried 500 passengers in its daily service. More planes are being acquired. B. M. Spencer and S. Purcell, formerly of the Army Air Service, are chief pilots.

On one occasion a vial of serum was delivered from San Francisco by one of the planes of this company in time to save the life of a woman in Marina.

Aircraft Protect $70,000,000 of Western Forest

Washington, D. C.—The Air Service announces that the three sections of forest now being protected by its aerial patrol have a total of 35,000,000,000 board feet of timber valued as follows: Tahoe National Forest, $18,000,000; Stanislaus National Forest, $19,280,000; Eldorado National Forest, $25,000,000. The acreage under direct observation is over 1,636,000. More than thirty fires have been located and put out before material damage was done.

Missouri Ranchmen Buy Curtiss Aeroplane

Boonville, Mo.—Six large Missouri property holders have purchased an aeroplane for the rapid inspection of their holdings. The plane is a Curtiss and has been flown by its pilot, Lieut. Russell Simmons, formerly of the Air Service, from Kelly Field to Boonville. The properties range between three and four thousand acres each, and at least one of them consists of scattered holdings.

Three Aviation Companies Organize in Spokane

Spokane, Wash.—Two aviation companies are in active business and a third in the process of organization in the vicinity of Spokane.

J. L. Justice, who has been appointed General Sales Manager of the National Wire Wheel Works

The Northwest Aircraft Company, this city, has two machines, one of which was designed and constructed by the company's own expert. Both machines have been used for exhibition purposes most successfully, and the company plans to enter commercial aviation on a comprehensive scale.

The latest entry in the aviation field is the Washington Garage in Yakima, which has received two machines from Mather Field, Sacremento. The aviators attached to this enterprise are Lieutenants R. P. Marshall and Floyd L. Kelso, late of the United States Aviation Service. Kelso's mother had never seen an aeroplane, but she flew from Yakima to her home in Kennewick with her son the day after his machine was delivered. The machine will be used for exhibition and instructional purposes. The company will operate an agency for aeroplanes.

The Western Aviation Company of Spokane is another concern from which considerable is expected. The company is understood to contemplate purchasing several aeroplanes in the very near future, and it is predicted that a substantial impetus will be given to aviation locally as a result of its activities.

Hartford Insurance Company Gets Proposal to Insure Passengers

Hartford.—The Travelers' Insurance Company is considering the proposal of an aeronautical company being formed in New York to insure the lives of passengers on dirigibles which it is proposed to operate between New York and South America. A life insurance policy would be sold with each ticket for passage.

The dirigibles would be intended principally for commercial traffic and would carry only a few passengers.

Browne Aerial Express Service Now Operating

The first aerial express line has been inaugurated by George W. Browne, of Milwaukee, Western representative of the Curtiss Aeroplane Corporation and distributer for Willys-Overland, Inc., by two planes of the Browne Aerial Express service.

These planes, carrying a consignment of tires for the Willys-Overland Company at Toledo, from the Federal Rubber Company of Cudahy, Wis., on the outgoing trip and a number of Overland automobile parts on their return, just completed a successful trial trip between Milwaukee and Toledo.

The two planes, piloted by Lieut. Milton Elliott and Lieut. Shirley Short, originally departed from Cudahy, Wis., with their cargoes of Federal tires, stopping at the Browne Aviation Field in Milwaukee. From there they flew to Chicago and thence to Toledo. On the return trip they transported a quantity of Overland parts to the Browne salesroom in Milwaukee.

The Use of Woodtite in Aircraft

The discovery of Woodtite, a scientific product of the Woodtite Laboratories of Modesto, California, has marked a new era in the wood-working industry, particularly the hard wood industry. As an industrial invention none was ever more oportune; first, because of new uses for hard wood under great stran, and, second because the best hard woods are now much scarcer than formerly, thus necessitating more frequent use of inferior qualities.

Woodtite is not a glue. It is an oil-like compound, devised to meet the universal requirements of an agent to swell shrunken wood permanently in all cases of loose joints. It also prevents warpage.

All wood is subject to swelling, shrinkage or warpage from climatic variations, no matter how much care is exercised in seasoning. Constant strain and severe service will also upset the exactness of joining and turning, be the workmanship ever so perfect. Hence the vital need of a neutralizing agent like Woodtite.

Hitherto Woodtite has been used chiefly in a product with the well known trade name of Spoktite for tightening loose wooden automobile wheels. It was an urgent need in this respect that really caused the invention of Woodtite. But now its use has extended throughout the whole wood-working industry. It has been found invaluable in fine cabinet and furniture making, and it is now being tried in aircraft construction where perfect joints in all wood-work is important for stability and permanency.

The Woodtite Laboratories at Modesto, California, have the best chemists and mechanics available, constantly at work on all sorts of tests for wood-work in aircraft and similar construction. They extend advice and the benefits of their researches to all who apply for assistance, without cost or liability to the enquirer. The makers of wooden parts for aircraft are especially invited to avail themselves of this source of co-operation and information.

R-34 Mail Arrives Eleven Days Sooner

Copies of New York newspapers of July 7, 8, and 9, the issues which were brought to England by the R-34 and delivered in London on July 13, were distributed through the ordinary steamship mail on July 24, eleven days later.

Curtiss Mail Plane Holds New York-Bellefonte Record

One of the new Curtiss HA mail machines, built by the Curtiss Aeroplane and Motor Corporation for the Post Office Department, recently broke all flying records between Belmont Aerial Mail Station, New York, and Bellefonte, Pa.—one of the legs on the newly completed aerial mail route between New York and Chicago. The journey of 220 miles was made in 105 minutes, including a stop of ten minutes. The previous record was held by one of the De Haviland mail machines. Pilot Stevens, who flew the ship, stated that the machine averaged 120 miles per hour over the course which is, for the greater part, over mountainous country. The HA machine was designed by the Curtiss Company and built around the Liberty Motor. It has a mail-carrying capacity of 900 pounds and, in a test performance, attained a speed of 145 miles per hour with a full load. It has a landing speed of 45 miles per hour.

Aerial Mail Strike Settled

The strike of the aeroplane mail pilots is definitely settled and the mails between New York and Washington and New York and Chicago are arriving and leaving on schedule. The settling of the strike was the result of a conference between six of the striking pilots and Otto Praeger, Second Assistant Postmaster General, in Washington, on July 27.

Headed by Pilot T. H. Anglin, the pilots went to Washington to lay their demands before Mr. Praeger and endeavor to prove to him that pilots with more than 500 hours' experience in the air could be better relied upon to judge weather conditions than the postoffice authorities and could decide when not to fly. The pilots were represented by Attorney James H. Conklin, of Bellefonte, Penn., and included Pilot E. Hamlin Lee, who was dismissed for refusing to take the air in a heavy mist.

Although the details of the conference were not given out, the Postoffice Department authorized a statement that a satisfactory conclusion had been reached and that the strike was the result of a misunderstanding.

The six aviators who refused to fly on July 25 with mail from New York to Washington and to Bellefonte, Penn., and from the latter city to Cleveland have been reinstated. They were dismissed for refusing to obey orders. However, the two pilots, Leon Smith and E. Hamilton Lee, whose dismissal on July 22 was directly responsible for the strike, have not yet been reinstated, it was said, as their cases would require further investigation.

The striking pilots claimed that when Smith and Lee refused to fly, there was a heavy rain and dense banks of mist. Flying under such conditions in the last two months, they said, had resulted in several accidents.

The visibility on July 22, when the aviators refused to fly, was said to be barely 100 yards. The R-4 mail planes drive ahead one and two-thirds miles every sixty seconds. They do not function properly at an altitude lower than 800 feet. Despite the appeals of pilots, they are not equipped with stabilizers, which, in case of fog, would inform the pilot whether he was flying right side up or upside down. The department thought them too expensive, it was said. The pilots said they cost $75.

Under such conditions, the pilots declared, any mail plane which took the air in rain and mist would be driving at a precariously low altitude over cities and villages at the rate of 100 miles an hour.

In reply to these charges Assistant Postmaster General Praeger made this statement:

"My attention has been called to newspaper statements containing charges said to emanate from air mail pilots. These charges, if they were true, are not sincere. They were not made before the dismissal of the two pilots in question and would not have been made if these two pilots had been reinstated or have been permitted to have their own way in the matter of the selection of types of planes to fly the mail.

"Any statement that a Curtiss R-4 plane with a Liberty motor is an unsafe ship is a calumny on our aeroplane industry. The statement that this type of plane cannot be flown at less than one hundred miles an hour is false and the pilots who are supposed to have made this statement know that they have to push the engine almost to its utmost limits of performance to get one hundred miles an hour out of this type of plane; also they know that its lowest flying speed is not in excess of fifty-five miles an hour, as demonstrated at a recent official test by the Air Mail Service. This is possibly five miles an hour more than the small type JN-4-H.

"There is no truth in the statement that the Postoffice Department is refusing to equip planes with gyroscope turn indicators. These instruments are in course of further development and refinement and are not obtainable in quantities on the market as yet. The indicators for the air mail service which are being developed will require two months' further work. The indicator will have to be further perfected, and this is what the Postoffice Department expects to accomplish.

"The department, however, cannot leave the question of when to fly and when not to fly in each instance for the judgment of a dozen different aviators. If this were done, it would be impossible to operate a mail schedule with any degree of dependability and the air mail would have to be abandoned."

First Aerial Trans-Atlantic Express Package on Display

New York, N. Y.—The shipment of platinum which was brought over by the great British dirigible R-34—the first ever to make the aerial passage—is now on exhibition in the window of Dreicer & Co., the Fifth Avenue jewellers.

The company announces that this precious consignment will be made into medallions commemorating the historic bridging of the Atlantic by the lighter-than-air type of aircraft.

New Bellefonte-New York Record

A record flight of ninety minutes from Bellefonte, Pa., to New York, on the last leg of the Chicago-New York route, was made by Pilot Stevens, who arrived at Belmont Park, L. I., at twenty-seven minutes before one o'clock on July 26, following the resumption of aerial mail service after the recent strike.

Aerial Weather Bulletin Issued

Washington, D. C.—The twice daily aerial weather bulletin is now being issued by the Air Service at all army flying fields, forecasting the conditions for flying for twenty-four hours, from 9:30 A.M. and 9:30 P.M. The country has been divided into zones, and the flying fields within each zone will receive the reports covering their locality. In addition, a special report will be telegraphed on request covering flights between the points named in the request, which should state the time of the contemplated start.

Daily observations at various altitudes will be taken by the Balloon Division at the following points: Arcadia, Fla.; Fort Omaha, Neb.; Akron, Ohio; San Antonio, Tex.; Hampton, Va., and from the aeroplane at Arcadia, Fla.; San Diego, Cal.; Allessandro, Cal.; Sacramento, Cal.; Rantoul, Ill. Houston, Tex.; Americus, Ga.; Washington, D. C.; New York, N. Y.

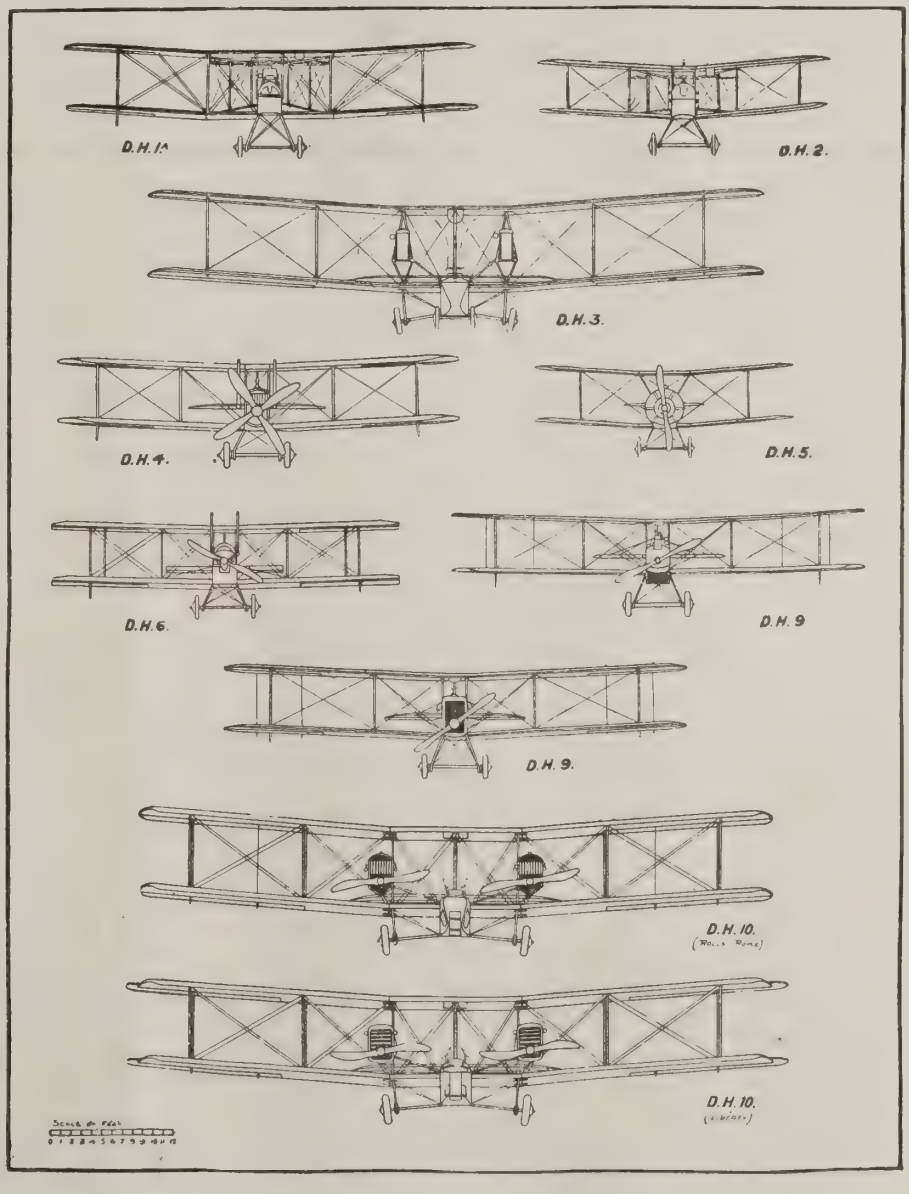
The data obtained will be handed the Weather Bureau and used in connection with reports received by them to aid the aerial forecast.

THE DE HAVILLAND AEROPLANES

The D.H. 1

A FEW months before the outbreak of war the Aircraft Manufacturing Co., Ltd., or, as the firm is now styled, the Airco., were fortunate enough to secure the services of Mr. (now Capt., R.A.F.) Geoffrey de Havilland, who had up till then been engaged as designer at the Royal Aircraft Factory (now Royal Aircraft Establishment) at Farnborough. The first machine designed by Mr. de Havilland for the Airco, made its appearance early in 1915. It was a two-seater of the pusher type, and during the preliminary trials, piloted by its distinguished designer, the machine gave promise of very good qualities, judged by the standard of those days. Although originally designed for a more powerful engine, the D.H. 1 had a very good turn of speed for its power—the engine fitted was a 70 H.P. Renault—and was inherently stable to a very great extent, de Havilland flying it repeatedly "hands off." The D.H. 1 had its seats so arranged in tandem that the gunner was in the front seat. The pilot sat behind the gunner and his seat was placed somewhat higher.

The D.H. 1A



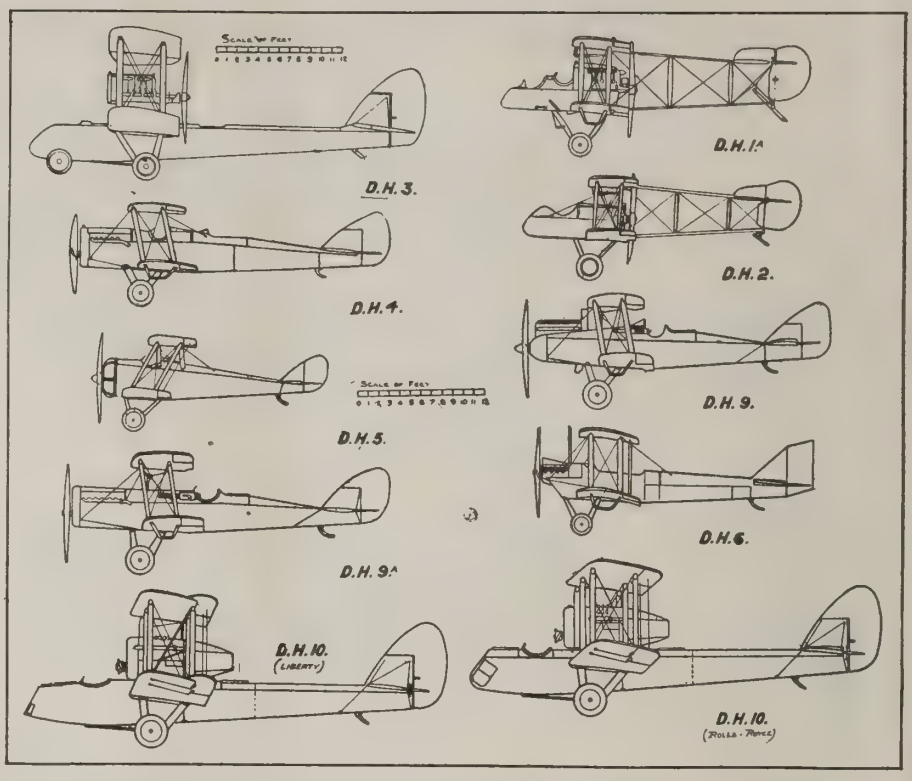
The D.H. 1 was followed by the D.H. 1A, which was practically identical, except that it was fitted with a 120 H.P. Beardmore engine. On the D.H. 1 the shock-absorbing arrangement consisted of coil springs taking the load, while the rebound was taken by a piston working in a cylinder filled with oil. This arrangement was discarded in the D.H. 1A for the ordinary rubber shock absorbers. Another experiment which was tried on the D.H. 1 was discarded in D.H. 1A, namely, the air brakes. These consisted, in D.H. 1, of two small monoplane wings, each of some 3 ft. span, mounted on the top longerons of the nacelle. In normal flight these wings were set at no angle of incidence, but for landing they could be rotated so as to present an area normal to the direction of flight. They were not a great success, however, and were not incorporated in D.H. 1A. To preserve the clean appearance of the nacelle, the radiator was not mounted on the sides, but was built into the front portion of the engine housing, just behind the back of the pilot. In addition to providing the cooling, this placing of the radiator may possibly have assisted materially in keeping the pilot warm. The performance of D.H. 1A was very good for its power, the speed being 89 M.P.H., and the climb to 6,000 ft. taking 12 mins. 10 secs.

The D.H. 2

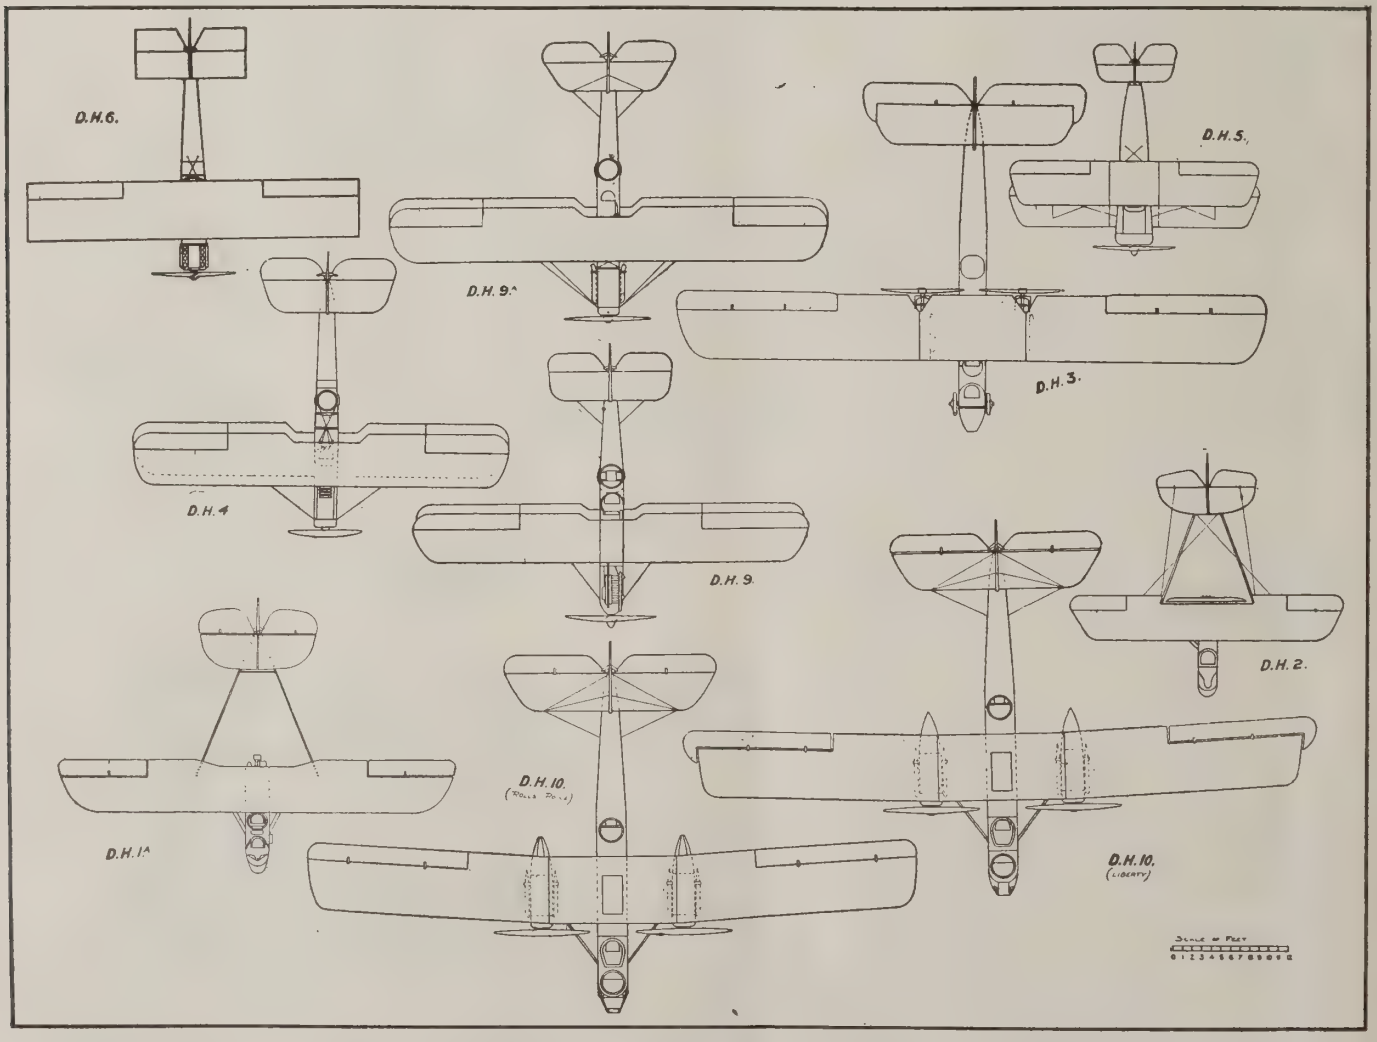
After the D.H. 1A came a little machine which startled everybody by what was in those days considered fine speed, and, especially, an excellent climb. This was D.H. 2, a little single-seater pusher scout with 100 H.P. Gnome monosoupape engine. When D. H. 2 came to be turned out in quantities it soon became a favorite for certain classes of work, and was used with great success on the Western front in the days before synchronized machine guns became the fashion. When this happened, the *raison d'être* for the pusher disappeared, and as this type could not be got to do the performance of tractors with the same power, it gradually ceased to be used. For comfort in flying, however, it is doubtful whether this type can be surpassed. There is no slip stream, and placed as he is in the extreme nose, the pilot can be seated low down and well protected from the wind, which, as a matter of fact, is only felt on a turn. The theory held at one time that this type is dangerous on account of the engine being behind the pilot is not, we think, borne out by experience, and we are not by any means certain that for pleasure flying the now rather despised pusher should be regarded as a thing of the past. As far as the Airco. is concerned, the D. H. 2 was their last single-engine pusher.

The D.H. 3

While thus engaged upon the production of small pusher scouts, Capt. de Havilland foresaw the need for larger weight-carrying machines, and designed a twin-engine machine which became known as the D.H. 3. It was a fuselage biplane with the engines placed between the planes and the fuselage placed rather low down. The latter feature somehow gave the machine an appearance of being, as someone put it, "a flying-boat on wheels." The accommodation of the occupants—the D.H. 3 carried three—was designed with a view to giving the two gunners—or bomb-droppers—a good view in all directions. The front gunner's cockpit was in the extreme nose of the fuselage. The pilot occupied the middle seat, and the rear gunner's cockpit was placed well back, clear of the trailing edge of the planes. The engines, two Beardmore 120's, were mounted on Vee struts between the wings, and drove, through an extension of the shaft, the pusher screws, which both revolved in the same direction. The tank capacity was sufficient for a flight of eight hours' duration, and as the military load was 680 lbs., the machine should have been quite a useful bomber, especially as her speed was 95 M.P.H. at low altitudes and only dropped to 88 M.P.H. at 9,500 ft. It might be mentioned that the body of the D.H. 3 was covered with three-ply wood, which



Front views of the De Havilland aeroplanes



further tended to make her resemble a flying-boat.

The D.H. 4

The next design to leave the drawing table of Capt. de Havilland was a two-seater tractor, D.H. 4. The power of the engine available had by then increased considerably, and it was possible to hope for much better performances from two-seaters than had hitherto been the case. This was the object of the D.H. 4. So as to give the gunner a better chance to use his machine-gun, his seat was placed far aft in the body, where he is well clear of the wings. The first D.H. 4 to make its appearance at Hendon was fitted with a B.H.P. engine of about 200 H.P., but later on engines of other makes were installed with great success. An examination of the accompanying tables will show the performance of the machine with the various engines that have been fitted from time to time. The high efficiency of the D.H. 4 has enabled the Royal Air Force to use it for nearly every purpose for which aeroplanes are used. It has done long-distance reconnaissance, bombing, photography, fighting, etc., and has also been extensively used for long-distance passenger carrying. According to the engine fitted the machine has varied a little from time to time, but the alterations have not been great. For instance, some D.H. 4's have had their exhaust collectors swept upwards so as to carry the fumes away

over the top of the upper plane. Also the shape of the nose when fitted with a vertical B.H.P. engine has naturally been somewhat different from the nose of the R.-R. engine one. No fundamental changes have, however, been made. It might be mentioned, as it is not shown in the table, the figures of which refer to the standard performance—that a D.H. 4 with a 200 H.P. B.H.P. engine has actually been flown at speeds varying from 42 to 127 M.P.H., which is "some" speed range. The covering of the fore part of the body of the D.H. 4 is of three-ply wood, which was a somewhat unusual feature in a British machine at that time.

The D.H. 5

The pusher scouts having become obsolete, partly on account of the relatively poor performance of this type of machine, and also by reason of the adoption of the synchronized machine gun, Capt. de Havilland set to work to produce a tractor scout in which he aimed, not only at drawing full advantage of the better performance inherent to the type, but also at providing, to as great an extent as possible, the same good view in a forward and upward direction as that enjoyed in the pusher scout. The outcome of these efforts was the D.H. 5, in which the chief characteristic was the negative stagger. This feature lent a curious appearance to the machine, and when she first appeared there were those who were inclined to regard her as a freak. It was not very long, however, before flying tests demonstrated that her performance was good for her power, and from the reports of pilots who had flown her it appeared that she was not unduly difficult to handle. That she had her own little idiosyncracies which had to be learned and humored may be admitted (every machine has), but after pilots got into her ways she soon became popular, and during 1917 she was used in great numbers with good success. Although fitted with a slightly more powerful engine than was the pusher scout—a 110 Le Rhone against a 100 Gnome monosoupape—it is interesting to compare the performance of the two types. The ground speed of the D.H. 2 was about 93 M.P.H. while the D.H. 5 does 105 M.P.H. at 6,500 ft. The climb to 10,000 ft. was accomplished by the pusher in 18 min., 30 sec., while the tractor does it in 12 min., 4 sec. It would, therefore, appear that the advantage of the tractor is greater in the case of speed than as regards climb. One is the features of the body design which is out of the usual run of bodies is the manner in which the rectangular section fuselage is faired. In section it is an irregular octagon while in side view the corners of this octagonal section forms straight lines.

The D.H. 6

Towards the end of 1917 the question of training pilots became pressing, and the need for a machine designed especially for school work became apparent. To meet this demand the D.H. 6 was designed. The objects kept in view in designing her were: Simplicity, and therefore ease of manufacture, maintenance and repair, interchangeability of parts, low landing and stalling speeds. Hence the straight tips and control surfaces. The flat, and nearly vertical, nose of the fuselage might be thought to offer unnecessary resistance. It should be remembered, however, that this is a school machine, and we believe we are correct in saying that this detrimental surface was intended to assist in safeguarding the machine against being dived at too high a speed by inexperienced pupils. For the same reason plain cables are used in the wing bracing. An ingenious quick-release dual system of control is fitted, by means of which the instructor can cut out the pupil completely by the movement of a single lever, and it should be particularly noted that this quick release includes not only aileron and elevator, but also rudder control. A remarkable feature of the D.H. 6 is the low speed at which it can be flown. The standard machine has a maximum speed of 75 M.P.H. and lands at about 30 M.P.H., while it may be actually flown at speeds below 30 M.P.H. The standard model is intentionally made slightly unstable for purposes of teaching, but a few slight modifications will turn it into a stable machine. Furthermore, by fitting streamline wires instead of the wing-bracing cables and by cowling-in the engine the maximum speed can be increased to 90 M.P.H. In this form the machine should be very well suited to pleasure flying, especially as it was primarily designed for cheapness of manufacture.

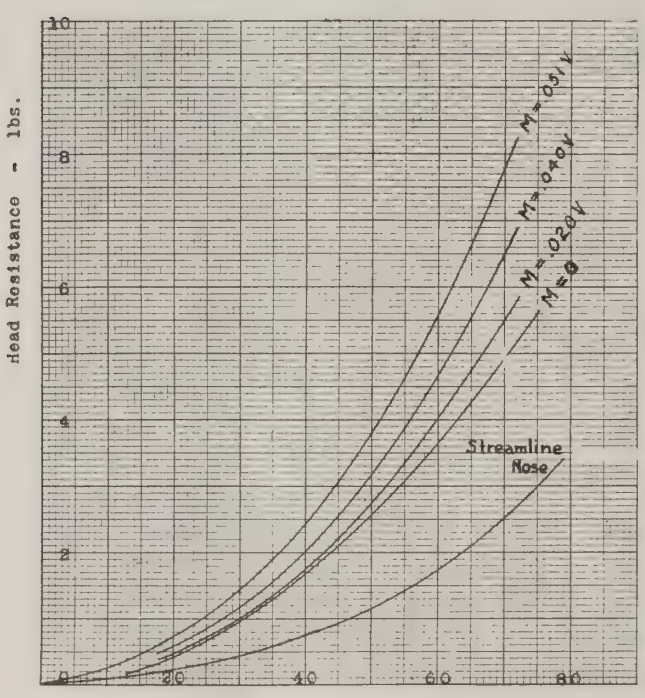
RESISTANCE DUE TO NOSE RADIATOR



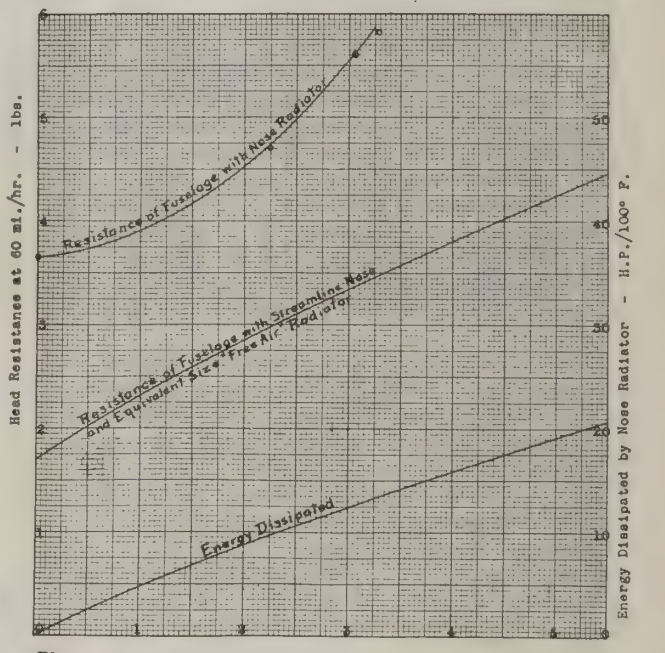
WIND tunnel tests on a model fuselage show the following qualitative results:

(1) *At any given plane speed* the total resistance of a fuselage with a flat nose radiator is increased by increasing the air flow through the radiator, either by opening exit vents for the air or by decreasing the resistance of the radiator to passage of air. This shows that a nose radiator—in contradistinction to a free air radiator—should be of compact construction with high heat transfer for low air flows through the core, therefore requiring a core of high resistance.

(2) *With varying plane speeds* the relative efficiencies of free air and nose radiators do not change.

(3) With all three widely differing types of core tried, the combined resistance of the fuselage and a free air radiator of given cooling capacity was from 10 to 50 per cent less than that of the fuselage with a nose radiator of the same core construction and equivalent cooling capacity.

(4) From other experiments performed at the Bureau of Standards it is clear that there is more chance for improvement in types of core for free air positions than in types of core for the nose position.



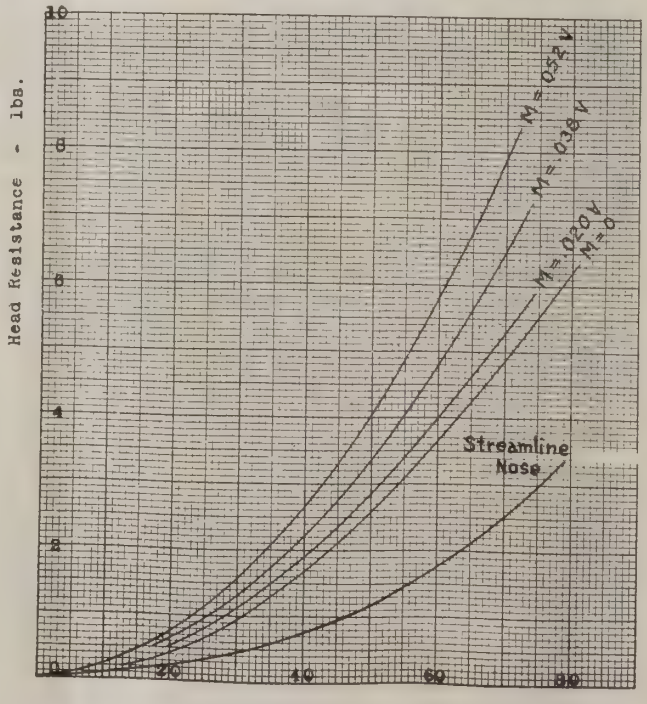
Plot 1. Free Air Speed—miles per hour (V) Resistance with various air flows (M) in lbs. per sec. per sq. ft. front, when V = free air speed in mi. per hr., compared with fuselage having streamline nose. Core No. A-23, Livingston 5/16" sq. cell, 5" deep

The present report considers the effect of placing a radiator in the nose of a fuselage as compared with the effect of placing a radiator of the same core construction, having an equivalent cooling capacity, in the free air and streamlining the nose of the fuselage. The results of these tests indicate less difference than would be shown by comparing results with radiators specially selected for each of the positions in which they were placed.

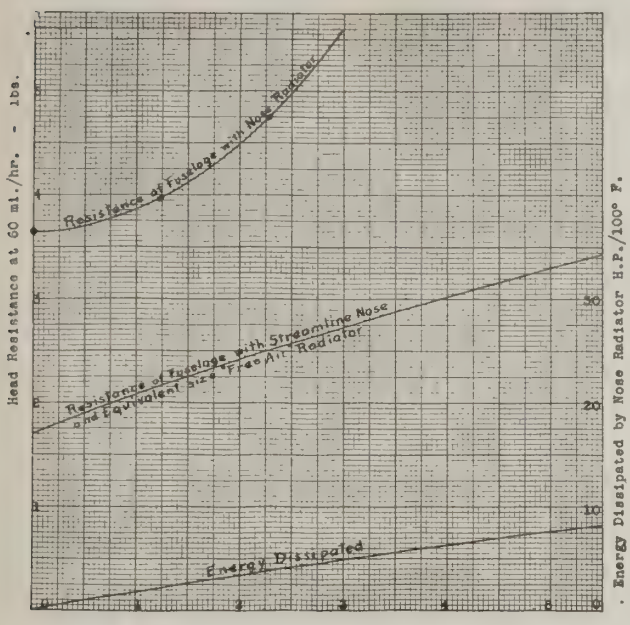
The results are qualitative only, but they are so striking as to indicate that the nose of the fuselage is not a desirable location for a radiator from the point of view of head resistance.

A model fuselage 60 inches long, 10 inches wide and 13 inches high was constructed with a removable streamline nose, which, when removed, allowed an 8-inch square section of radiator core to be placed in the nose. Two holes on each side of the fuselage, each about 1½ by 6½ inches, were cut about a foot back from the nose and fitted with adjustable sliding doors. By adjusting these vents the amount of air passing through the nose was varied.

The model was mounted in a 54-inch wind tunnel and the head resistance measured under the following conditions:



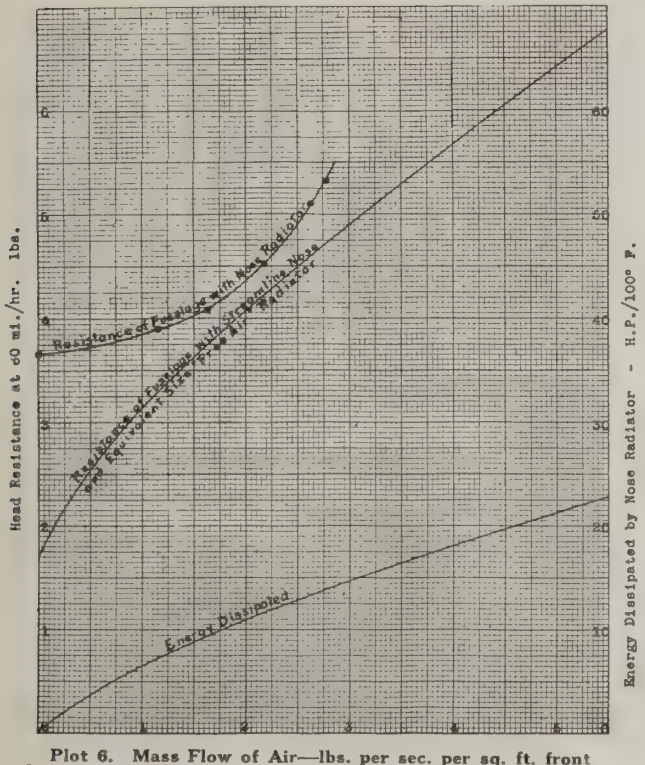
Plot 2. Mass Flow of Air—lbs. per sec. per sq. ft. front Core No. A-23, Livingston 5/16" sq. cell, 5" deep. Section of core 8" square in nose of model 60" long, 10" wide, and 13" high. Free air speed 60 M.P.H.



(1) Streamline nose on model. (No change in resistance was observed whether vents were open or closed.)

(2) Streamline nose removed, but nose radiator covered with a sheet of paper so that there was no air flow through the core. (3), (4) and (5) Nose radiator in place with varying amount of air flow controlled by opening the vents. Seven or eight different air speeds were tried in each case, the maximum being 70 miles per hour.

The results of these runs are given in plot 1, against free air speed. They show (1) that the streamline nose decreases the resistance of the fuselage by 50 per cent, and (2) that the total resistance of the fuselage increases rapidly when air is allowed



Plot 3. Free Air Speed—miles per hour (V) Resistance with various air flows (M) in lbs. per sec. per sq. ft. front, when V = free air speed in mi. per hr., compared with fuselage having streamline nose. Core No. B-1, Candler ⅜" hex. cell, 2½ in. deep

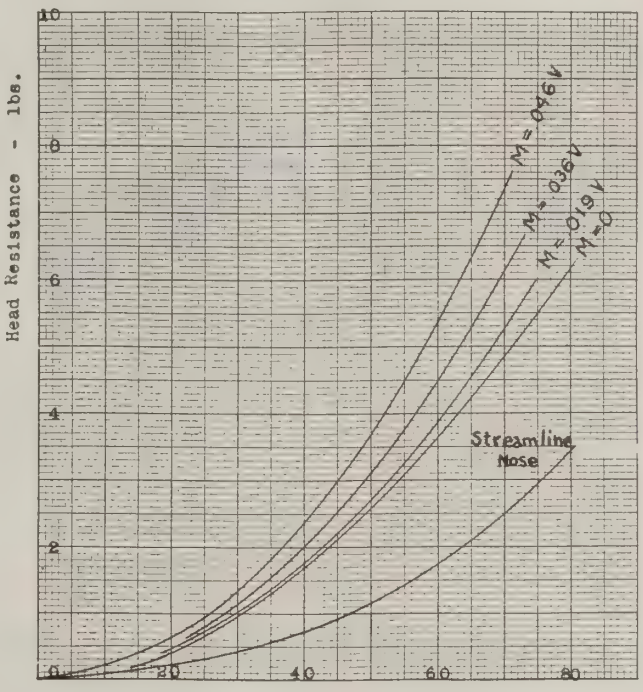
Plot 4. Mass Flow of Air—lbs. per sec. per sq. ft. front Core No. B-1. Section of core 8″ square in nose of model 60″ long, 10″ wide, and 13″ high. Free air speed 60 M.P.H.

to enter the radiator, so that a compact type of core is desirable for this position.

Plot 2 illustrates these conclusions more clearly, since there the resistance of the fuselage at 60 miles per hour free air speed is plotted against the mass flow of air through the radiator. There is also plotted the total resistance of the fuselage with a streamline nose, together with a free air radiator of the same core construction and of such size as to have a cooling capacity equivalent to that of the nose radiator at any given mass flow. Plots 3, 4, 5 and 6 give the same data for two other cores, 3 and 4 being for a core of very low head resistance and 5 and 6 for a core of very high head resistance, which would be a very good type for a nose radiator and a very bad type for free air. These are types of core considerably better for free air positions than those included in this test, while the core represented in plots 5 and 6 is probably one of the best for the nose position.

Plot 6. Mass Flow of Air—lbs. per sec. per sq. ft. front Core No. G-3. Section of core 8″ square in nose of model 60″ long, 10″ wide, and 13″ high. Free air speed 60 M.P.H.

Conclusions



Based on the results of these wind tunnel experiments on a model fuselage, it is concluded that:

(1) The resistance of a fuselage with streamline nose is increased more by removing the streamline nose and substituting a radiator than it is by adding an equivalent free air radiator and retaining the streamline nose.

(2) Between good radiators for each position the increase of resistance due to the nose radiator is roughly double that due to the free air radiator.

(3) Above a very low mass flow, the nose radiator becomes relatively worse and worse as the mass flow is increased by opening the vents at a constant free air speed. This fact is of great importance, since the space available for a nose radiator is so limited that the highest possible mass flows are used in practice.

(4) It is found that the relative efficiency of the nose radiator and the free air radiator does not change appreciably with free air speed for a given setting of the vents.

Plot 5. Free Air Speed—miles per hour (V) Resistance with various air flows (M) in lbs. per sec. per sq. ft. front, when V = free air speed in mi. per hr., compared with fuselage having streamline nose. Core No. G-3, Spirex, 3⅜ in. deep

Gluing Veneer at High Moisture Contents

It is common practice among plywood manufacturers to dry veneer down to very low moisture contents before gluing it. The object in doing so apparently is to prevent shrinkage of the veneer and consequent marring of the appearance of the finished panel. The drying is done in plate redriers, textile driers, or similar apparatus, and adds appreciably to the cost of manufacturing panels.

That such preliminary drying may not be necessary is indicated by the results of a recent investigation by the Forest Products Laboratory. Veneer panels were glued with casein glue at various high moisture contents (some over 50 per cent), and in various tests proved as strong and as desirable as those made under drier conditions. In fact, in the moisture resistance tests a considerable proportion of the veneer which had been dried before gluing showed signs of failure, whereas veneer glued at a moisture content of 15 per cent or higher gave practically perfect results. Panels made at high moisture contents checked if dried too rapidly, but this difficulty could be avoided by proper operation of the kiln.

It seems possible, therefore, that the cost of producing panels of certain kinds may be very materially lessened through the use of water resistant glue and the reduction or even elimination of preliminary drying. Very dry veneer is more likely to break or split than damp veneer; an additional saving is therefore possible through a reduction of waste.

The use of moist veneer, of course, is not practicable for some purposes, but it is quite certain that much of the veneer which is now being painstakingly dried before gluing might advantageously be glued at a higher moisture content.

THE SMITH PARACHUTE

THE U. S. Army, having placed very rigid requirements for parachutes, found practically all available types below the requirements for strength. Test strength consists of a test equivalent to carrying a man weighing 200 pounds, traveling at a speed of 300 miles per hour.

The chute designed by Mr. Floyd Smith of McCook Field has been developed and has passed this test on numerous occasions. Although this chute is not considered the last word and experiments are still in progress with a view to improving it, it is thought by officers of the Army Air Service to be best on the market to-day, either foreign or domestic.

This chute is of a flat type, 28 feet in diameter, with a 42-inch patent shock absorbing vent supported by 40 silk shroud lines of 250 pounds breaking strength. The shroud lines are arranged in four groups of 10 each tied to a D ring, which in turn is sewn into the harness webbing. The D ring has a strength of 5,000 pounds, and the webbing fails at 3,400 pounds. No. 8 Mommo Shantung silk, having a tensile strength of 56 pounds per inch laterally and 42 pounds per inch lengthwise, is used for fabric, which gives a strength far greater than the other parts of the chute.

The total weight of the pack complete is 12 pounds 4 ounces. Several different types of packs have been devised in order that they may not prove a burden to the wearer. The accompanying photographs show the pack, which is 18″ x 12″ x 3″, carried on the back, acting at the same time as a cushion in a specially designed seat. This pack can be operated either by attaching the rip-cord to the plane, or the wearer can pull it himself, either before or after jumping, depending upon the circumstances.

© Underwood & Underwood

Parachute nearing the ground after a 1,000 foot drop

Numerous tests have proved the absolute necessity of the aviator being well clear of the machine before the opening of the chute to avoid having it carried into the tail surfaces by the very high velocity slip stream. The advisability of having the chute entirely free from the plane has been well demonstrated also. The fact that the two main conditions calling for the use of a parachute are, first, fire danger, and second, the collapse of some vital part of the plane, logically the aviator in both of these cases wishes to clear the machine without depending on it in any way for the sucessful operation of his chute. Criticisms have been made in regard to the inability of the aviator to separate the release, or neglecting to do so, but drops by men entirely inexperienced in parachute jumping have proved to the contrary.

Future developments will probably follow very closey the lines as described in this chute in regard to operation. Undoubtedly there is a great deal of work still to be done on the best shape of chute. Although the Smith chute can be steered a limited amount, further development along this line may be expected.

NAVAL and MILITARY AERONAUTICS

55,000,000 Miles Flown in 18 Months

United States Army pilots flew 55,671,120 miles in the eighteen and a half months, between January 1, 1918, and July 17, 1919, according to an announcement made by the Director of the Air Service.

The figure is based upon an estimate of sixty miles for each hour of flying. This is a very low estimate, since most of the planes used could and did fly at rates between seventy-five and 120 miles an hour without counting the wind velocity, which at times reduced or raised their speed. The number of hours spent in the air by the army pilots was 927,852, about 106 years. It is hard to give an idea of what 55,671,120 miles means. It is equivalent to 2,227 circumnavigations of the globe at the equator. It is more than half the distance to the sun.

Kelly Field No. 2, at San Antonio, Tex., led all the rest in the matter of hours flown. The pilots of this field remained in the air 167,982 hours, more than nineteen years. Ellington Field, at Houston, Tex., was a moderately good second with 95,293 hours. The reason why Texas is the banner State for flying was that its fine climate and long stretches of flat lands, making perfect landing fields, caused it to be chosen for much of the training of new fliers. Rockwell Field, at San Diego, Cal., was third on the list, with 61,659 hours flown. At Hazelhurst Field at Mineola only 4,529 hours, in about six months, was flown.

No More Exhibitions Where Inadequate Landing Facilities Exist

Washington, D. C.—The announcement made by Major General Charles T. Menoher, Director of Air Service, to the effect that no further exhibition flights will be made at cities where inadequate landing fields are provided, serves as a warning to those who desire to reap the benefits which accrue from the use of aircraft, that the establishment of adequate landing facilities is an urgent necessity.

General Menoher in his statement refers to an accident which occurred in Boston at the only available landing field, and which was the result of the limitations of the field. No flights will be made over Boston until a suitable aerial landing field is provided, including satisfactory means of keeping spectators off the field while landings and starts are being made.

Eighth Aero Squadron at Border

McAllen, Tex.—The Eighth Aero Squadron, consisting of 18 officers and 107 men, arrived here recently with an equipment of twelve aeroplanes.

Air Service Less Than One-Tenth War Strength

Washington, D. C.—The Air Service reports a net decrease in the total commissioned and enlisted strength from the date of the armistice to July 10 of 91 per cent.

The following table shows the present distribution of personnel as compared with the latest revised figures of November 11, and the per cent decrease. The July 10 figures do not include 432 officers and 816 enlisted men in transit or at demobilization stations awaiting discharge.

	Nov. 11	July 10	Per cent net decrease
Cadets	6,483	7	99.9
Enlisted men.	167,986	13,597	92
Officers	20,554	4,432	78
Total	195,923	18,036	91

NC-4 to Make Recruiting Flight up Mississippi

New York, N. Y.—After being exhibited for two weeks in Central Park, the NC-4, which made the first trans-Atlantic flight in history, is being dismantled for shipment to the Rockaway Naval Air Station. Here she will be completely overhauled preparatory to a recruiting flight upon which she will be manned by the same crew which took her successfully across the Atlantic.

Her itinerary will include the principal cities of the Atlantic and Gulf Coasts, probably a flight up the Mississippi, a circle of the Great Lakes and in all likelihood a visit to the Pacific Coast via the Panama Canal. California is bringing strong pressure to bear for a visit by the ship. Definite dates and stopping points have not been decided on.

150 Air Service Officers in Regular Establishment

Washington, D. C.—There are in the Air Service 149 flying officers of the regular establishment, thirteen of whom are balloonists and six observers. Of the 130 pilots many have flown only the training plane. A large percentage are beyond the age limit for pursuit pilots. A minority, who went overseas and became squadron or group commanders, are in condition for active flying duty.

In the following table is shown the distribution of the regular flying officers by rank. Of 130 captains of the line, 121 hold military aviator or junior military aviator ratings, which makes them majors in the Air Service, and of the fourteen first lieutenants of the line three hold the same ratings which advances them one grade in the Air Service.

	Temporary rank	Rank held as M.A. or J.M.A.	Regular line rank
Brig. General	2	..	..
Colonel	17	..	..
Lt. Colonel..	50	2	2
Major	66	123	0
Captain	8	10	130*
1st Lieut.....	6	11	14
2nd Lieut....	0	3	3
Total	149	149	149

*One captain retired.

Recruiting for Naval Air Service Resumed

Washington, D. C.—Recruiting for the naval aviation service has been resumed. All men in class V of the Naval Reserve, who are now on inactive duty who are desirous of joining the regular force as aviation mechanics, may be enlisted as apprentice seamen and will then be given rating in the aviation branch. These men will have their choice of transfer to the aviation mechanics school at any of the following naval air stations: Chatham, Mass.; Rockaway, N. Y.; Cape May, N. J.; Hampton Roads, Va.; Key West, Fla.; Pensacola, Fla.; Akron, Ohio; San Diego, Cal.; Coco Solo, C. Z.; or the Naval Training Station at Great Lakes, Ill.

NC-2 to Be Put in Commission

Washington, D. C.—It is stated that the NC-2 will be repaired and placed on active duty. This flying boat differs from her sister ships in that her four motors are arranged in two pairs of one pusher and one tractor units. The NC-4 is to be placed on exhibition at the Smithsonian Institute. The NC-1 is at the bottom of the Atlantic and the NC-3 is dismantled and in storage.

Air Service Represented On Pyrotechnic Signal Board

Washington, D. C.—A Board of Officers is being convened to meet on August 1, 1919, at Ft. Sill, Oklahoma, for the purpose of developing a system of pyrotechnic signals and drawing up specifications for suitable pyrotechnic material. The following officers constitute the Board: Lieut. Colonel W. B. Harding and Major A. B. Quinton, Ordnance Department; Lieut. Colonel H. C. Tatum, Cavalry; Lieut. Colonel E. R. Coppock, Infantry; Captain D. H. Arthur, Air Service, and Lieut. Colonel H. Parkhurst, Field Artillery. It is directed that the Chief of Ordnance, Director of Air Service and Commanding General of Fort Sill render such assistance as is desired by the Board where such is possible.

FOREIGN NEWS

Aeroplane Transport Scores Beat for London Paper

A very fine object-lesson is afforded of the superiority of the aeroplane in times of emergency over other orthodox forms of communication, in the hustle which Mr. Ward Price, the *Daily Mail* correspondent, indulged in on Peace-signing day, last Saturday. Immediately after the signature of the Peace Treaty in the Hall of Mirrors, Mr. Price motored to Buc, and, there taking an aeroplane, reached London in time to write a complete story of the happenings for the edition of the *Weekly Dispatch* published at 3.30 on Sunday morning. By way of contrast, the Paris Post Office was congested with telegrams, some of which took 24 hours to reach London.

Through Mr. Ward Price's flight the *Weekly Dispatch* was enabled to publish a much fuller account of the signing than any other Sunday paper, in addition to a whole page of photographs taken during the afternoon, which were also brought by aeroplane.

Argentine Aviators Arranging Plymouth-Buenos Ayres Flight

Three flying men from South America, Capt. Angel M. Zuloaga (commander), Capt. Annibal Briguega (navigator), and Eng. Ambrosio Taravella (mechanic), are visiting London with a view to completing preparations for a flight from Plymouth to Buenos Ayres *via* Portugal and Africa, some 8,000 miles, the Atlantic crossing, representing about 1,500 miles.

The flight may be made in an F-5 flying boat if one can be purchased from the British Government.

Airship Service Between Milan and Venice

It is reported from Milan that the airship service between Milan and Venice has been inaugurated. The dirigible "F. 6" left Buggio, near Milan, with 30 passengers on board, on June 23, while at about the same time the "N. 14" left Campalte, near Venice, carrying 20 passengers. Both airships are said to have made the journey successfully.

Aerial Mail Service to Foreign Countries Contemplated by British Post Office

London.—An aerial mail service to foreign countries is being seriously considered by Great Britain, the assistant postmaster announced in the House of Commons on July 18. It might not be long, he said, before mails would be carried to Australia, China, and elsewhere in a comparatively few hours, revolutionizing mail transportation.

Danish Government Buys Bristol Planes

The Danish Government has taken a decided step in the direction of the speedy development of aerial navigation between Denmark and the neighboring countries. A considerable number of Bristol biplanes have been acquired on behalf of the nation and are now on their way to Denmark. Accompanying them are a number of skilled British airmen, who are to act as instructors of the Danish pilots to be employed on the projected services. By reason of its peninsular formation, Denmark has always suffered many of the handicaps of isolation. The tedious sea journey to the other countries of Scandinavia or to Britain, or the inconvenient train route through Hamburg to the rest of Europe have militated against the speediest trade relations, and it is to obviate these limitations that extensive aerial services are now being organised.

Mexican Soldiers Bomb Comrades

It is reported that Government planes, scouting for Villa bandits, sighted a unit of Government infantrymen under the command of General Pablo Gueroga, and dropped a number of bombs among them. The casualties are not yet reported.

French Government Plans Long Distance Flights Over European Capitals

Paris.—The French Aeronautical Department has arranged for a series of long-distance flights to be made by war pilots over various capitals. London, Madrid, Constantinople, Prague, Warsaw, Vienna, Brussels, Amsterdam, and Cairo (via Constantinople) are included. Trips will also be made to Tunis, Algiers, and Dakar (West Africa).

French Aviation Mission for Turkey

Paris.—The French Chamber is expected to vote additional credits for the establishment of an Aviation Mission in Turkey, entrusted with the organization of the following postal lines: Constantinople, Smyrna, Grecian Archipelago; Constantinople, Palestine, Messa, Egypt; Constantinople, Armenia, Caucasus, Persia; Constantinople, Bucharest, South Russia; Constantinople, Salonika, the Balkans. It is stated that these lines will be carried on by the military until French air navigation companies have been floated.

Swedish Midget Plane Tested

Stockholm.—A trial flight of an experimental midget aeroplane constructed at the Paalson works of Malmoe is reported to have been successful. The machine is said to weigh only 700 lb., and it is capable of carrying another 400 lb. The body is described as cigar shaped, and constructed so as to reduce the air resistance to a minimum. It has a Thulin 50 h.p. Gnome engine of special construction, capable of giving a speed of about 80 miles an hour.

Avro Passenger Carrying Service Profitable

The A. V. Roe Co. have secured the services of Lieut.-Col. G. L. P. Henderson and placed him in charge of the passenger carrying service. The aerodrome is at Hounslow; although this locality is said to be quite inaccessible to the metropolis, seven aero machines: two five-seaters, two three-seaters, a dual control two-seater, a Baby Avro and a three-seater limousine are in constant service. The fee is over $5.00 and from 250 to 300 passengers are carried on Saturday. Monday, the poorest day, averages 60 passengers, and the total average is over a hundred per day.

Deutsch De La Meurthe Gives Two Million Francs for Flying Meets

Paris.—M. Henri Deutsch de la Meurthe, President of the Aero Club of France, has given the club a generous gift of two million francs for the purpose of organizing flying meets.

German Aero Transport Firms Active

Advertisements are being carried by German papers announcing that an air service has been started by the Luft Fahrzewg Ges. from Stralsund to Sassnitz, Binz, Sellin, Gohren and connecting with the Berlin-Stralsund line. The rates for passengers from the above seaside resorts is 150 marks, and the fare from Stralsund to Berlin, 600 marks.

The Hamburg-American line advertises daily freight and passenger service between Berlin, Leipsig—Weimar, Berlin—Hanover—Gelsenkirchen, Berlin—Hamburg.

Rome-London Flight Planned

The Fiat Co. is arranging for a non-stop flight from Rome to Kenley, near Croydon, a distance of 1,100 miles.

British Policy of Scrapping New Planes Criticized

London.—Considerable discussion has been aroused by the scrapping of new machines and engines, which has been going on in Great Britain.

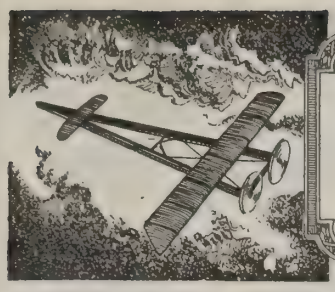
Vast numbers of new aircraft have, immediately on completion, been sent to the Government-owned aircraft factories throughout the country to be burned and the waste thus caused has been stupendous.

The latest report of the Select Committee on National Expenditure makes a point of the fact that numbers of new aircraft were accepted from their constructors and sent straight away to these national factories to be destroyed.

The report states that following the armistice, the Air Council met and decided to inform the Ministry of Munitions that they required no more aeroplanes. This decision, however, was not adhered to, and in December last they wrote to the Ministry of Munitions stating that they appreciated that labor and other considerations might prevent the Ministry of Munitions from arranging a complete cessation of further deliveries, and for this reason the Air Council would accept aircraft and engines of which production is required by these considerations.

The report proceeds: "Accordingly, machines were taken in large numbers from contractors, which were not wanted, and as national factories had to be kept going, it was necessary to find work for the people there, with the result that the machines taken from contractors to keep the people at the contractors' factories employed, were sent to the national factories to be destroyed, in order to keep the people at the national factories employed."

It must be remembered that England had for more than four years been working up a maximum production in aeroplanes. The armistice came almost as a surprise and it was utterly impossible to at once bring the wheels of production to a standstill.



Aeronautical Intelligence Bureau Formed in England

The Aeronautical Intelligence Bureau, Ltd., was incorporated on June 13th. The chief objects are: (A) To unite and combine aeronautical firms for the purposes of mutual advancement and protection. (B) To protect the members of the Society from financial risks by obtaining and distributing information concerning firms undeserving of mercantile credit. (C) To keep a register of bankrupt persons and those in winding up or liquidation. (D) To procure the amendment or repeal of legislation injurious to the members. (E) To procure information as to the standing of firms.

Other points are:—(1) That members are entitled to unlimited investigations. (2) That no member's interests are divulged to another without his written assent. (3) That ordinary letters will take the place of the usual stereotyped inquiry forms. The offices are at 30, Bedford Row, W. C., London.

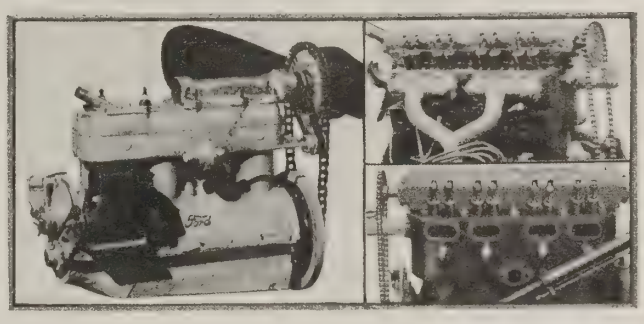
INTEREST in the light type aeroplane is growing, more so now than before, perhaps, owing to the returning aeroplane pilots and mechanicians released by the Government.

All of these young men want to fly, and as many are unable to buy or build a large heavy motored machine they are naturally turning to the next best type, or what we call the light type machine.



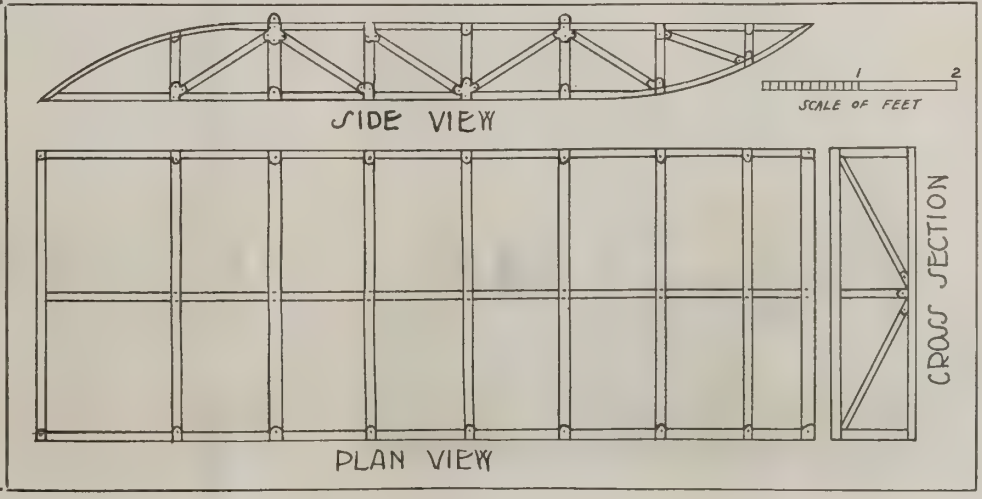
The aeroplane accessory and motor firms have anticipated this, and many accessories and parts for constructing these little machines are offered for sale all over the United States. The motorcycle machine recently described on this page met with a great deal of favor from the readers, but owing to its small reserve horsepower it cannot be called a capable machine.

The Ford motored aeroplane, which had for its power plant a redesigned Ford motor, has been taken seriously by the readers after first fears and surprise that the Ford should be strong enough to carry a big machine into the air and fly it at speeds up to 60 miles per hour. The Ford motor is flying aeroplanes to-day all over the country, and many firms are specializing in Ford motors redesigned for aeroplane work.

A new motor is that produced by the Craig-Hunt Company, which was developed for racing cars, but can be used in aeroplanes as well, and should be an improvement over the old form of motor not having the overhead valves. It is claimed that a speed of 90 miles per hour has been made with a specially made up car with this power plant. The valves are operated by an overhead camshaft, which is driven by a chain and gear arrangement. There are four valves to each cylinder, two intake and two exhaust, located overhead and seated at an angle of 20 degrees.

The valves are 1½ inches in diameter and operated in pairs by rocker arms of the forked type. Each rocker arm is operated by the overhead camshaft, which runs on three ball bearings, all of which are enclosed in an oil-tight aluminum housing. The cams are of the roller follower type, each of which dips in oil and lubricates the roller end of the rocker arm.

There are two spark plugs to each cylinder, set below and



between the valves on each side of the head. The intake manifold is so arranged as to allow the installation of either a 1¼ or 1½-inch carburetor.

Of course for aeroplane work the heavy flywheel and transmission is done away with, as the propeller acts as a flywheel, and if pistons and connecting rods are carefully weighed to be sure that they are all the same weight, all vibration will be eliminated and the engine should perform well.

The Ford motor can be successfully used in an aeroplane without the use of an overhead attachment, but if one can be purchased light enough so as not to increase the weight too much, it would be better to employ one. From time to time we will show different Ford motor inventions as well as those for other motors that will increase the power and revolutions per minute.

This motor should be compared with the one built by P. P. Belt of Fredonia, Kan., which he used in his pusher type aeroplane with great success, giving a thrust of 350 pounds. This motor was a regular Ford with a special bearing block fastened to the top of the motor with the cylinder head bolts, to which the propeller was fastened. This motor was described in February 24th issue.

The accompanying drawing shows the general outline and method of construction for the pontoon to be used with the Ford Motored Aeroplane described in "Aerial Age" some time past. The general description of this pontoon appeared in "Aerial Age" last month

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Dirigible Balloonacy

The *Aeroplane,* a British publication, thus discusses an article which was published recently in an American periodical dealing with the uses of airships in times of peace. The following suggestions are made:

"'The dirigible will be useful to the Bureau of Mines because it can carry prospectors at low altitudes as they search for symptoms of minerals.

"'In tropical forests trees of great value can be hunted for by their flowers, leaves or other symptoms seen from above.

"'In countries where migratory insects like locusts need surveillance, scientific measures can be taken to find their breeding places and sterilize the egg-laden areas. A dirigible can follow a locust cloud and by the use of gases and explosives disperse it or drive it away from valuable crops.

"'The Revenue Guards and the Department of Justice can use the dirigible to detect smugglers and to pursue large bands of outlaws, especially if they are mounted or have stolen live stock or property in vehicles.'

"One does not know which suggestion to admire most. The bombing or gassing of locusts appear to be the most practical, and would seem to provide better sport than the hunting of trees by their symptoms.

"The pursuit of large bands of outlaws seems to offer great possibilities. Large bands would, of course, be chosen, because the smaller bodies of bandits would not have sufficient strength to pull down the dirigible in order that they might be arrested."

Has anyone suggestions of similar character to offer for the application of aircraft to commercial uses? The Aeronitis editor will be glad to receive them with a view of publishing the most practical suggestions.

Air and Water

—From *The Dallas News*

Farewell, O Pioneer

Farewell, O pioneer
Of skyland's infinite realm!
You fought through fog and gale,
With heroes at your helm;
With luck invoked, you sail.
The path you bravely laid
Will broaden with the coming day,
The trip you dared and made
Unites our lands another way.
Farewell, O pioneer!

—*M. J. A., in New York Times.*

Overheard During the Visit of the R-34

Bystander throwing lighted match down on the ground. "I can't see why they won't let us go closer to the darn thing."

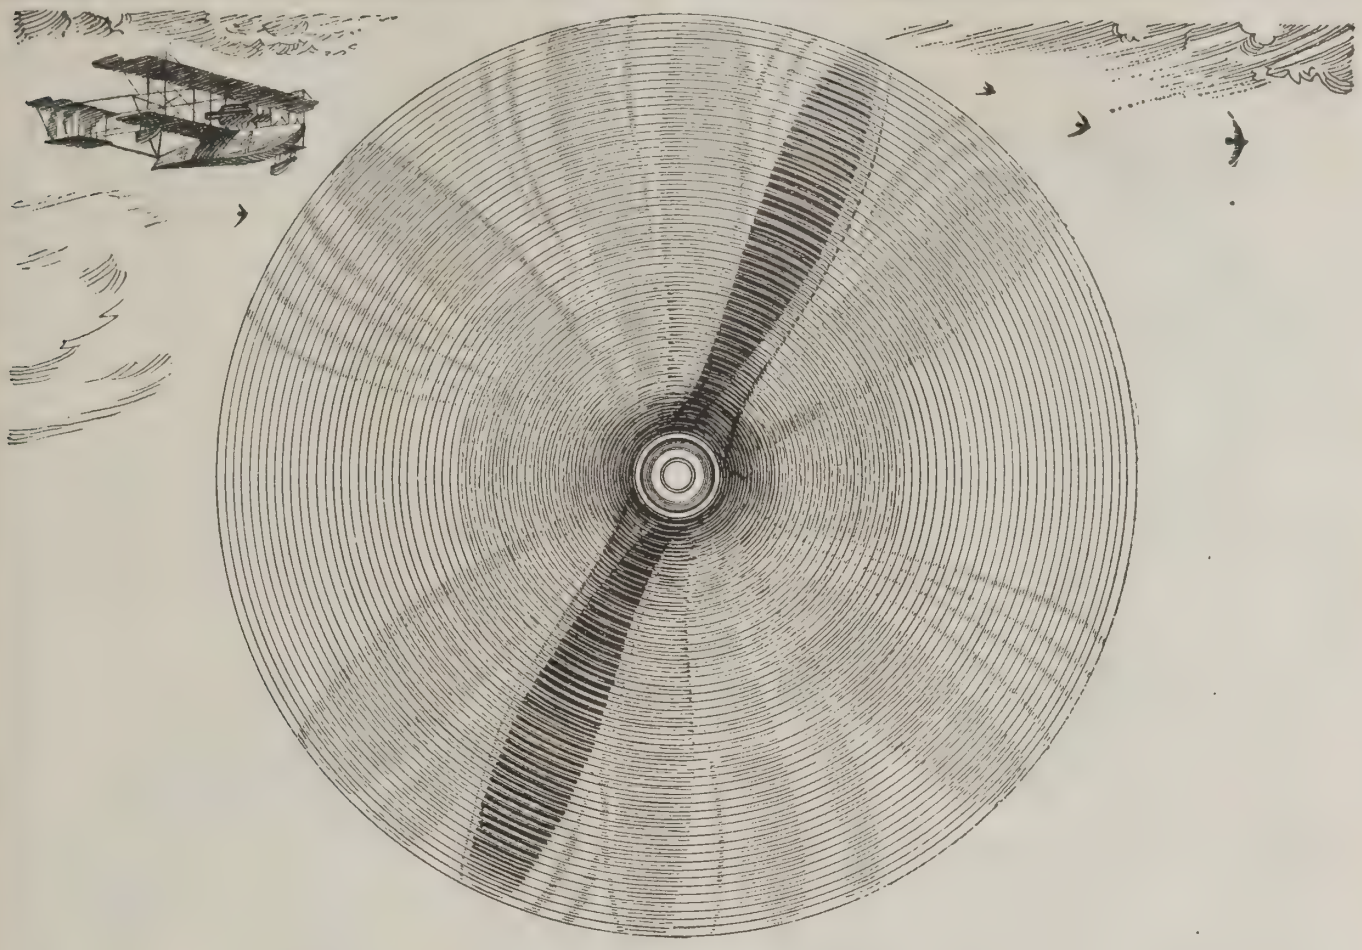
"My," said a sweet young thing, ambling about the side lines to a sweaty, tired guard, "does the wind make that balloon sway like that?"

"Naw," replied the guard in disgust, "they're just feeding it meat."

One dear old lady, with silver hair, remarked to her husband, who had no hair, "I just know it must be awfully hard for those poor men to hold on when the captain decides to loop the loop."—*Air Scout.*

The moral pointed by the behavior of the R-34 at Mineola would seem to be: You can't keep a good blimp down.—*Evening Mail.*

Kiwi or Kiwi-Kiwi



Kiwi—the Maori name for this queer *bird*—which was introduced in England by Mr. Lesson in 1823, is now generally adopted in all countries. It is easily distinguished from all its allies because of such a small body and comparatively small head and eyes. This curious flightless bird with its functionless wings and long thin legs is one of the most characteristic fowls of New Zealand. Zoologists placed it with the Penguin class. It is of a rich brown color with longitudinal yellow stripes and when grasped feels very soft—just as if its body contained no bones.

Kiwis have been seen on high hills but are met with mostly at very low levels. Parties from six to twelve were once seen but now flocks can hardly be hoped for. In the daytime they are very shy and inactive. When disturbed while sleeping they have a peculiar way of yawning. If molested they ruffle up their plumage, snap their bills, and make a loud noise which resembles a little growl. On moonlight nights they are seen running wildly through the woods, flapping their wings frantically and whistling loudly, attempting to fly as the other birds do. The Kiwi then is a bird which creates a lot of noise but cannot fly..

L. A. R.

(Kiwis may be seen at almost any aerodrome more than two years in existence.—Ed.)

The most terrific varnish test in history!

700 miles an hour for 26 hours—*and Valspar won*

DURING the trans-Atlantic flight of the NC-4 the strain on her huge Valsparred propellers was *terrific*.

The big blades, whizzing at 1800 revolutions a minute, attained at their tips the frightful speed of 700 miles per hour—a speed at which the drops of moisture striking their Valsparred surface had the impact of buckshot.

This amazing propeller speed was maintained throughout the entire 26 hours of trans-Atlantic flight—all the way from Newfoundland to Portugal—through blinding fog and mist.

Never yet has any varnish been called on to undergo such a terrific test. Had even a very little water penetrated the varnish, the tips of the blades would have begun to "fray." Then the laminated strips would have swelled and separated and the blades of the propellers would literally have flown to pieces, landing the NC-4 on the ocean, helpless.

But Valspar protected these laminated propeller blades perfectly, as it did all other varnished parts of the NC-4.

Valspar's toughness, elasticity and waterproofness *made good* for the U. S. Navy in this severe trial. It is the one varnish that can be *absolutely depended upon* under all conditions of air service.

The D.H. 7 and D.H. 8

We now come to a short gap in the series of D.H. machines. The next two types, we understand, never got any further than the drawing-board stage, and we have not been able to obtain any particulars of them.

The D.H. 9

The experience gained with the D.H. 4's demonstrated that placing the pilot in between the planes did not tend to give him an ideal position for fighting, and also when bombs had to be carried little space was left in the part of the machine where they could be most suitably placed; that is, in the neighborhood of the c.p. These drawbacks were remedied in the D.H. 9, by rearranging the pilot's seat considerably farther aft than it was placed in the D.H. 4, and, of course, readjusting the position of other weights in relation to the wings so as to maintain the longitudinal trim of the machine. The fitting of a vertical engine instead of a Vee enabled the designer to narrow down the front portion of the fuselage considerably, which resulted in a fuselage of beautifully clean lines with, it may be assumed, a comparatively low resistance. One of the features which has helped to give this machine its clean appearance is the placing of the radiator, not in the nose, as in the D.H. 4, but in the floor of the body. An ingenious feature of this radiator mounting is that the radiator can be moved up or down, thus varying the cooling to any desired extent by blanketing a larger or smaller portion of the cooling surface. The machine has been extensively used for fighting, reconnaissance, photography, etc., and also by the Independent Air Force for long-distance bombing by day and by night. It was the D.H. 9 which was largely used for the day bombing raids on German towns.

In connection with the D.H. 9 it is of interest to note that one of these machines fitted with a 420-H.P. Napier "Lion" engine did a speed of 140 M.P.H. at 10,000 ft., which altitude it reached in the extraordinary short time of 8 min., 10 sec. The same machine, furthermore, had a ceiling of 29,000 ft., although with a load slightly lighter than the standard.

The D.H. 9A

With the insistent demand for better and still better performance the necessity of fitting engines of greater power became urgent, and the D.H. 9A was produced to meet these demands. Except for the front portion of the body it was not greatly different from the D.H. 9. It has, however, a somewhat larger area, so as to obtain the same landing speed for the heavier weight. The object had in mind when designing the D.H. 9A was to provide an improvement on the 9, namely, to carry a greater load while maintaining a high performance. Apart from being extremely useful for long-distance reconnaissance, photography and fighting, this machine has been largely used for long-distance day bombing raids. The accompanying table will give a good idea of the manner in which the designer succeeded in attaining his purpose, and it is of interest to mention the following facts in addition: By increasing the military load from 545 lbs. to 945 lbs. the speed at low altitudes is reduced to 125 M.P.H., and at 10,000 ft. to 114½ M.P.H. The climb to 10,000 ft. with this load occupies 15.05 minutes and the ceiling is 19,000 ft. The range is reduced to 620 miles. (The reduction in speed is largely due to the fact that the extra load in bombs is carried outside.) By way of showing the weight-carrying capacity of this machine it is of interest to note that it has flown successfully with a military load of 1,325 lbs.

A machine of this type has also been fitted with a 360 H.P. Rolls-Royce engine, and, carrying a military load of 1,745 lbs., reached a ceiling of 16,500 ft. with a speed of 107½ M.P.H. at 10,000 ft. This machine differed from the standard 9A in that its fuel tankage was only 71 gallons, having a larger margin for load. It should also be noted that the above speed was reduced by about 4 M.P.H., owing to the bombs and carriers being put outside.

The D.H. 10 and 10A

The object in designing this machine was to produce a high performance, self-defending, long-distance daylight bomber. The armistice came along before the D.H. 10's were built in great numbers, and so this type has not had the opportunity of proving itself to the same extent on active service as have the other types of D.H.'s. Judging from its performance, however, it is safe to say that it would have proved a formidable antagonist. It will be seen from the table that when carrying three men, 1,000 lbs. of bombs, full military equipment, and sufficient fuel for a flight of 700 miles, the performance is so extraordinarily good as to be superior to any German machine *of any type whatsoever*. The machine would, therefore, be able to go out over the lines with its tanks full for a long journey and with a heavy load of bombs, and yet be entirely immune from enemy attack by aeroplanes. This may be regarded as an achievement to be proud of in a daylight bomber. The manœuvrability of the D.H. 10A is as good as is its performance, and one of these machines has been looped by the late Capt. B. C. Hucks.

BOOK REVIEWS

AVIATION ENGINES, *by Lieut. Victor W. Pagé.* A complete practical treatise outlining clearly the elements of internal combustion engineering with special reference to the design, construction, operation and repair of aeroplane power plants; also the auxiliary engine systems, such as lubrication, carburetion, ignition and cooling. It includes complete instructions for engine repairing and systematic location of troubles, tool equipment and use of tools, also outlines the latest mechanical processes. Price $3.25, post paid.

AERONAUTICAL ENGINES, *by Francis John Kean.* This volume has just been revised and enlarged and therein is comprehensively explained several types of aeroplane motors, such as Curtiss, Mercedes, Gnome, Anzani Ten-Cylinder Radial Air-Cooled Aero engines, etc. It also contains numerous plates and is fully illustrated. Price $2.75, post paid.

DYKE'S AUTOMOBILE AND GASOLINE ENGINE ENCYCLOPEDIA. The author has brought out this 1919 edition to further educate the readers of this Encyclopedia and to broaden their knowledge on points overlooked in previous editions. If you are interested in engines of every description and type, such as those installed in automobiles, motorcycles, motorboats, aeroplanes, etc., you should be an owner of this volume. It is valuable on account of its complete and thorough information. Price $4,50, post paid.

HIGH SPEED INTERNAL COMBUSTION ENGINES, *by Arthur W. Judge.* This volume is the outcome of an endeavor to collect and to classify, in as brief a form as possible the more important information relating to the subject of high speed internal combustion engines, as viewed from the theoretical and experimental sides. It treats of the thermodynamics of the internal combustion engines, explosion and combustion in the engine, conditions occurring in actual engines, pressures and temperatures in internal combustion engines, indicators and indicator diagrams, mechanics of the high speed internal combustion engines, and engine balance. It is fully illustrated and contains many valuable tables. Price is $7.50, post paid.

THE A B C OF AVIATION, *by Victor W. Pagé.* A non-technical manual, containing instructions for lining up and inspecting typical aeroplanes before flight and also gives easily understood rules for flying. It treats of aeroplane fuselage construction, power plants, propeller construction and action, equilibrium and control principles, uncrating, setting up, and aligning, inspecting aeroplane before flight, and also contains a most complete nomenclature of aeronautical terms. Price $2.75, post paid.

THE PRINCIPLES OF AEROPLANE CONSTRUCTION, *by Rankin Kennedy.* This work is intended to show the principles of the aeroplane as applied to flying machines and to put in as concise a form as possible the theory of the plane, commencing with the elementary laws of mechanics and the inclined plane, afterward giving the formulae for the determination of the principal dimensions of the aeroplane in the simplest form, with numerically worked out calculations on the two systems in use. Price $2.20, post paid.

PRACTICAL AVIATION, *by Charles B. Hayward.* A thoroughly comprehensive volume treating of several phases in aeronautics, such as: Dirigible Balloons, Theory of Aviation, Design and Construction of Aeroplanes, Aviation Motors, Types of Aeroplanes, Military Uses of Aeroplanes, Building and Flying an Aeroplane, etc. This is an extremely popular publication. Price $4.00, post paid.

PROPERTIES OF AEROFOILS AND AERODYNAMIC BODIES, *by Arthur W. Judge.* A technical treatise compiled for use among aeronautical engineers, draughtsmen and students. This is fully illustrated and contains many valuable tables. It is intended to form a companion volume to the author's "Design of Aeroplanes." Price $6.30, post paid.

LANCIA AVIATION MOTOR
FOR SALE

This motor has been run only 10 hours in a test for the U. S. Government at McCook Field. The test showed it developed 320 h.p. at 1,380 r.p.m. and weighs 740 lbs. Surprisingly low gas consumption. It is unquestionably one of the most efficient 12 cylinder aviation type motors in the world. A number of spare parts is included with the motor, such as a complete set of extra cylinders, pistons, water pumps, etc. Can be inspected any time.

Special Orders Nos. 156 to 161 Inclusive

Second Lieut. Charles C. Chauncey will proceed to Caldwell, N. J., to the commanding officer Air Service detachment national rifle range, for the purpose of participating in national rifle matches.

Second Lieut. Edward N. Fortson will proceed to Houston, Tex., and report in person to the commanding officer Ellington Field for duty at that place.

The following-named officers will proceed to Riverside, Calif., and report in person to the commanding officer March Field for duty: George W. Puryear, Daniel F. Hunter, John T. Lawson, Thomas J. Guy, Jesse A. Madarasz, Paul L. Williams and Cutter P. Davis.

Second Lieut. John T. Eagleton is transferred to United States Army General Hospital No. 41, Fox Hill, Staten Island, N. Y.

First Lieut. Julian C. Stanley will report to United States Army Air Service Hospital, Cooperstown, N. Y.

First Lieut. Norman K. Berry is transferred to the United States Army Air Service Hospital, Cooperstown, N. Y.

Second Lieut. Frederic L. Gallup will proceed to Detroit, Mich., reporting to the commanding officer Aviation General Supply Depot for discharge.

Lieut. Col. Joseph T. McNarney, junior military aviator, will proceed to Godman Field, Camp Knox, Stithton, Ky., take station, assume command, and report by letter to the Director of Air Service, Washington, D. C., for duty.

First Lieut. Frank W. Wells will proceed to Detroit, Mich., report in person to the commanding officer Aviation General Supply Depot.

Maj. John G. Thornell will proceed to Hampton, Va., and report in person to the commanding officer Langley Field.

First Lieut. Jesse W. Simpson will proceed to Middletown, Pa., and report in person to the commanding officer Aviation General Supply Depot.

Maj. Edward L. Hoffman, junior military aviator, will proceed to Dayton, Ohio, and report in person to the Chief, Engineering Division, Air Service.

Maj. John C. McDonnell, junior military aviator, will proceed to Aberdeen Proving Grounds, Aberdeen, Md., take station, assume command of Air Service troops at that station and report by letter to the Director of Air Service, Washington, D. C.

Maj. Cushman A. Rice will proceed to Cooperstown, N. Y., to the commanding officer military hospital for observation and treatment.

Col. William H. H. Hutton, Jr., will proceed to Louisville, Ky., for the purpose of carrying out the verbal instructions of the Chief of Staff in connection with the delivery of distinguished service medal awarded Lieut. Col. E. V. Sumner, deceased.

Lieut. Col. Ralph Royce, junior military aviator, will proceed to Fort San Houston, Tex., Southern Dept., on temporary duty in the office of the department Air Service officer in connection with reorganization of Air Service troops.

First Lieut. Jesse B. Howe will proceed to San Antonio, Tex., to Aviation General Supply Depot.

Capt. Ormsby McCammon will proceed to Washington, D. C., and report in person to the Director of Air Service for duty.

Maj. Jacob H. Rudolph, junior military aviator, will proceed at once to Caldwell, N. J., and report in person to the commanding officer Air Service Detachment, National Rifle Range, for the purpose of participating in national rifle matches.

Maj. Victor M. Dumas will proceed to Washington, D. C., and report in person to the Director of Air Service for the purpose of conference, not to exceed two days; thence to Hazelhurst Field, Mineola, Long Island, N. Y., for duty.

Maj. Albert D. Smith is transferred to the Letterman General Hospital, Presidio of San Francisco, Calif., for observation and treatment.

Capt. Jesse K. Freeman will proceed to Morrison, Va., and report in person to the commanding officer Air Service Depot for duty.

First Lieut. LeRoy E. Hussell will proceed at once to Caldwell, N. J., and report to the commanding officer Air Service Detachment, National Rifle Range, for the purpose of participating in the national rifle matches.

First Lieut. Jack E. Duke, Jr., will report in person to the Director of Air Service, Washington, D. C., for assignment to duty.

Second Lieut. Stanley Wilson will proceed to Aviation General Supply Depot, Detroit, Mich.

Second Lieut. Carl E. Rollins will proceed to Hazelhurst Field, Long Island, N. Y.

First Lieut. John G. Fleming is detailed for duty with the Motor Transport Corps. He will proceed to Chicago, Ill., and report to the commanding officer, Motor Transport General Depot.

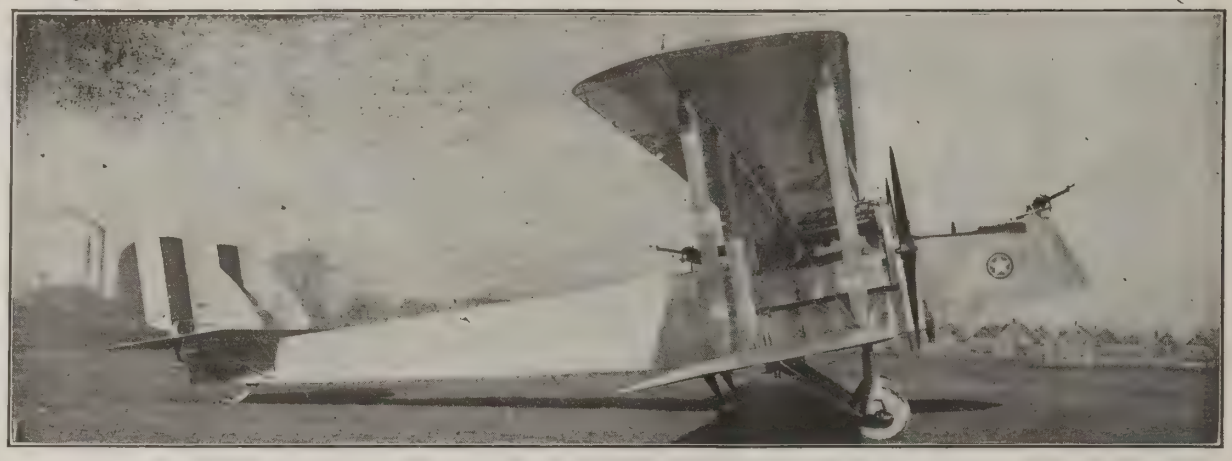
The following-named officers will proceed to the hospitals specified and report in person to the commanding officer thereof for duty:

D. P. A. Willard, United States Army General Hospital No. 19, Oteen, N. C.

Henry F. Wilstrey, Walter Reed General Hospital, Takoma Park, D. C.

Second Lieut. Bert Paul Meyen will proceed to Cooperstown, N. Y., and report in person to the commanding officer United States Army Air Service Hospital for observation and treatment.

Second Lieut. Carrol B. Crossan will proceed to Hazelhurst Field, Long Island, N. Y., and report in person to the commanding officer for duty.



First Lieut. John O. Donaldson will proceed at once to Caldwell, N. J., and report to the commanding officer Air Service Detachment, National Rifle Range, for the purpose of participating in national rifle matches.

Second Lieut. Howard D. Norris will proceed at once to Caldwell, N. J., and report to the commanding officer Air Service Detachment, National Rifle Range, for the purpose of participating in national rifle matches.

Second Lieut. George G. Cressy will proceed to Middletown, Pa., and report in person to the commanding officer, aviation general supply depot, for duty. The travel directed is necessary in the military service.

Paragraph 25, Special Orders, No. 142-O, War Department, June 18, 1919, relating to First Lieut. Samuel M. Lunt, Air Service (Aeronautics), is hereby revoked.

Second Lieut. William Prickett is announced as being on duty requiring him to participate regularly and frequently in aerial flights from November 26, 1917, to May 17, 1918, inclusive.

TRANS-CONTINENTAL AERIAL MAIL PROPOSED

CONGRESSMAN JULIUS KAHN introduced in the House of Representatives on July 30 a bill for the establishment of aeroplane mail service between New York and San Francisco. The terms of the bill are as follows:

"Be is enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the Postmaster General be, and he is hereby, authorized to expend, out of any unappropriated balance of the appropriation 'for inland transportation by railroad routes and aeroplanes,' appropriated by the Act entitled 'An Act making appropriations for the service of the Post Office Department for the fiscal year ending June 30, 1920, and for other purposes,' approved February 28, 1919, for the purchase of aeroplanes and the operation and maintenance of aeroplane mail service between the cities of New York, State of New York, and San Francisco, State of California; and the Postmaster General is authorized to designate such additional points between said cities as he may deem necessary or advisable for the operation and maintenance of an aeroplane mail service between said additional points, to be included in the service to and between said cities of New York, New York, and San Francisco, California."

BILL INTRODUCED TO ESTABLISH A DEPARTMENT OF AERONAUTICS

CONGRESSMAN CURRY of California introduced a Bill in the House of Representatives on July 28 which is designed to establish a Department of Aeronautics. The Bill follows:

A Bill to Establish the Department of Aeronautics, and for other Purposes

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That there shall be at the seat of government an executive department to be known as the Department of Aeronautics, and a Secretary of Aeronautics, who shall be the head thereof, who shall be appointed by the President, by and with the advice and consent of the Senate, who shall receive a salary of $12,000 per annum, and whose term and tenure of office shall be like that of the heads of the other executive departments, and section 158 of the Revised Statutes is hereby amended to include such department, and the provisions of title 4 of the Revised Statutes, including all amendments thereto, and hereby made applicable to said department.

The said Secretary shall cause a seal of office to be made for the said Department of Aeronautics of such device as the President shall approve, and judicial notice shall be taken of the said seal.

SEC. 2. That there shall be in said Department of Aeronautics an Assistant Secretary of Aeronautics, to be appointed by the President, by and with the advice and consent of the Senate, who shall receive a salary of $5,000 per annum. He shall perform such duties as shall be prescribed by the Secretary or required by law. There shall also be one assistant and chief clerk and a disbursing clerk, and such other clerical assistants as may be required from time to time and authorized by the Secretary. Until such time as an Auditor for the Department of Aeronautics may be authorized by law the Auditor for the War Department shall receive and examine all accounts of salaries and incidental expenses of the office of the Secretary of Aeronautics, and of all divisions and offices under his direction, and certify the balances arising thereon to the Division of Bookkeeping and Accounting of the Treasury Department, and send forthwith a copy of each certificate to the Secretary of Aeronautics.

SEC. 3. That it shall be the province and duty of said Department of Aeronautics to foster, develop, and promote all matters pertaining to aeronautics, including the purchase, manufacture, maintenance, and production of all aircraft for the United States and to perform all duties heretofore assigned to the War, Postoffice, and Navy Departments in so far as they relate to aviation, which shall include the supply of personnel and equipment for aerial mail routes, the preparation of aerial photographs, and the granting of aviators' and aeronauts' licenses to civilian pilots, and the promulgation of rules and regulations to govern such aviators and aeronauts; the supervision and establishment of aerial landing fields, including the supervision of those used for commercial purposes; the furnishing of personnel and equipment for coast, border, and forest reserve patrol, the instruction, training, and equipping of air forces for the national defense, and the development of heavier and lighter-than-air aeronautical material, and fostering such development for commercial purposes; to establish and maintain an aeronautical academy and such aircraft factories as may be hereafter authorized by law; and to this end it shall be vested with jurisdiction and control of departments, bureaus, offices, and branches of the public service hereinafter specified, and with such other powers and duties as may be prescribed by law: *Provided,* That the Secretary of Aeronautics shall submit to the Congress not later than six months after the passage of

this Act detailed estimates for the establishment of an aeronautical academy for the training of cadets in the science of aeronautics, who shall be commissioned in the regular air force when graduated, and for the establishment of such aircraft factories as may be required for the manufacture of aeronautical equipment and material.

SEC. 4. That all unexpended appropriations which shall be available at the time when this Act takes effect in relation to the various offices, bureaus, divisions, and other branches of the public service, which shall by this Act be transferred to or included in the Department of Aeronautics, or which may hereafter, in accordance with the provisions of this Act, be so transferred and such proportionate part of any unexpended balances of appropriations as the War Department and the Navy Department would have been required to expend for the pay and allowances on account of officers, enlisted men, and civilian employees transferred to the Department of Aeronautics by this Act, including medical attendance, transportation, housing, subsistence, clothing, and any other items not specially set aside for aviation purposes shall become available, from the time of such transfer, for expenditure in and by the Department of Aeronautics and shall be treated the same as though said branches of the public service had been directly named in the laws making such appropriations as parts of the Department of Aeronautics, under the direction of the Secretary of the said department. The Secretary of War, the Secretary of the Navy, and the Postmaster General shall, and are hereby directed, by order in writing, to transfer and deliver to such agents of the Department of Aeronautics as the secretary thereof may designate, all aircraft, including airships, hydroplanes, hydroaeroplanes, seaplanes, balloons, and any other means of transportation, including ships, vessels, boats, and automobiles or other motor vehicles, now in ues or on hand, and all material and parts, and all machinery, appliances, and equipment held for use for the maintenance thereof, all lands, docks, wharves, buildings, repair shops, warehouses, and all other property heretofore used by the Department of War, Department of the Navy, and Postoffice Department in, or in connection with, the operation, maintenance, and manufacture of aircraft, or procured and now held for such use by or under the jurisdiction and control of these departments.

SEC. 5. That the following named offices, bureaus, divisions, and branches of the public service, now and heretofore under the jurisdiction of the War, Navy, and Postoffice Departments, and all that pertains to the same, known as the Aviation Section of the Signal Corps, the Division of Military Aeronautics, the Bureau of Aircraft Production, the Air Service of the Army, the Motor Transport Corps, the Naval Flying Corps, the Marine Corps Flying Corps, and the Aerial Mail Service, and any and all other branches of the public service which has been heretofore charged with matters pertaining to aviation be, and the same are hereby, transferred from the War, Navy, and Postoffice Departments to the Department of Aeronautics, and the same shall hereafter remain under the jurisdiction and supervision of the last-named department and the Secretary of Aeronautics is hereby given the power and authority to rearrange the work of the offices, bureaus, and divisions confided to such departments, and to consolidate any of the offices, bureaus, and divisions transferred to said department. The official records and papers now on file in and pertaining exclusively to any bureau, office, department, or branch of the public service in this Act transferred to the Department of Aeronautics, together with the furniture now in use in such bureau, office, department, or branch of the public service, shall be, and are hereby, transferred to the Department of Aeronautics.

SEC. 6. That all clerks and employees of the War Department, the Navy Department, the Postoffice Department, or other bureau, office, department, or branch of the public service engaged or on duty exclusively pertaining to aviation and aeronautics shall be, and are hereby, transferred to the Department of Aeronautics at their present grades and salaries.

SEC. 7. That the air force of the United States shall consist of the Regular Air Force, the Reserve Air Force, the National Guard Air Force, while in the service of the United States, and such other air forces as are now or may hereafter be authorized by law.

SEC. 8. That the Regular Air Force of the United States shall consist of such squadrons, groups, wings, or other units designated by the Secretary of Aeronautics, to be known as the Line of the Air Force, an Operations Division, an Administration Division, a Legal Division, an Engineerng Division, a Supply Division, and a Medical Division, to be known as the Staff of the Air Force, within the limitations of this Act. The Line of the Air Force shall be so trained as to comprise a combatant force of the United States with a view to operating with the armed land and sea forces of the United States while in actual combat, and such other duties as the Secretary of Aeronautics may prescribe. The President shall be, and is hereby, authorized to assign such units of the Department of Aeronautics as may be necessary for cooperation with the armed land and sea forces of the United States in time of war or threatened hostilities and during maneuvers, target practice, and such other exercises as may be held by those forces: *Provided*, That in time of war or threatened hostilities, when such units are so assigned, they will be under the command of the designated commander of the land or sea forces, or both, as the case may be.

SEC. 9. That the duties of the Operations Division shall be to prepare plans for the national defense and for the mobilization of the air forces in time of war, to investigate and report upon all questions affecting the efficiency of the air force and its state of preparation for military or naval operations, to render professional aid and assistance to the Secretary of Aeronautics and to general officers and other superior commanders and to act as their agents in informing and coordinating the action of all the different officers who are subject under the terms of this Act to the supervision of the Chief of Operations, and to perform such other aviation duties not otherwise assigned by law as may be from time to time prescribed by the President. The Administration Division is charged under the direction of the Secretary of Aeronautics and subject to the supervision of the Chief of Operations in all matters pertaining to the command, discipline, or administration of the air forces, with the duty of recording, authenticating and communicating to troops and individuals in the air forces all orders, instructions, and regulations issued by the Secretary of Aeronautics through the Chief of Operations, of preparing and distributing commissions, of managing the recruiting service, and publishing and recording such other matters pertaining to aeronautics and the air forces as the Secretary of Aeronautics may direct.

The Legal Division will be charged, under the direction of the Secretary of Aeronautics, with all legal matters pertaining to the Department of Aeronautics, and will be charged with the care of records, and all general courtsmartial, courts of inquiry, and aeronautical commissions, and of all papers relating to the title of lands under the control of the Department of Aeronautics, except the public buildings and grounds in the District of Columbia. The officers of this division will render opinions upon legal questions when called upon by proper authority.

The Engineering Division is charged, under the direction of the Secretary of Aeronautics, with the selection and determining of types and designs of all aircraft equipment and material, including ordnance and communicating equipment and material, and the repair and maintenance thereof; it shall operate and maintain such aircraft factories as may be hereafter authorized by law, and such repair and machine shops as may be authorized by the Secretary of Aeronautics; the production, experimentation, and manufacture; the production, operation, and maintenance of aerial photographic apparatus; preparation of aerial photographic maps of the United States and its Territories and its possessions, and in field operations, of aerial maps of the theater of operations and such other aeronautical engineering duties as may be assigned by the Secretary of Aeronautics.

The Supply Division will be charged, under the direction of the Secretary of Aeronautics, with the duty of providing transportation, clothing and equipage, and barracks, storehouse, hangars, and other buildings; constructing and repairing landing fields and roads; the building, chartering, and operation of ships, boats, docks, and wharves needed for aeronautical purposes; supplying subsistence and articles for sale and issue to those entitled thereto; supplying, distributing, and accounting for funds for the payment of the Air Forces, and such other financial duties as are specially assigned to it; and attending to all other matters connected with supply and accounting which are not expressly assigned to some other division of the Department of Aeronautics.

The Medical Division is charged with the duty of the care of sick and wounded, making physical examinations of officers and enlisted men, the management and control of hospitals, and furnishing all medical and hospital supplies; with the duty of maintaining sanitary conditions for the Department of Aeronautics.

SEC. 10. The President is hereby authorized to appoint and commission in the Regular Air Force, by and with the advice and consent of the Senate, such officers as are hereinafter authorized: *Provided*, That the commissioned strength of the Regular Air Force shall consist of one major general, who shall be Chief of Operations, and, under the direction of

(*Continued on page* 1021)

The News of the Week

Roland Rohlfs Climbs to 30,700 Feet in Curtiss Triplane

An altitude of 30,700 feet was reached by Roland Rohlfs, chief test pilot for the Curtiss Engineering Corporation, according to his barograph, in a flight from Roosevelt Field on July 31. He started the flight at 2:33 P. M. and landed at 5:32 P. M.

The best previous American record was that of Major R. W. Schroeder, U. S. A., who attained an altitude of 28,900 feet in a British-built Bristol machine, Sept. 18, last year. The world's record is claimed in behalf of Adjutant Casale, a French man, who was reported last month to have reached a height of 33,136 feet.

Adjutant Casale's record has not been "homologated," or registered as official by the air societies of the world, although it may be received later. After the flight of Rohlfs the barograph was signed by the official witnesses and sent to the Aero Club of America to be corrected and authenticated. It may stand as the official world's altitude record.

Rohlfs flew a Curtiss Wasp triplane equipped with a twelve-cylinder 400-horsepower Kirkman motor. This machine is known as Type 18-T Triplane, described in the March 31 issue of Aerial Age. He tried out the climbing powers of the machine on July 25 in an unofficial flight, in which he reported reaching a height of 31,000 feet. Numerous witnesses were called to make the flight official, and the barograph was signed by Major J. E. Roessel, Major H. F. Miller, Lieutenant Colonel W. L. Moose, Jr., Captain A. F. Simonin, Colonel Archie Miller, Augustus Post, on behalf of the Aero Club of America; John T. Tarbox, secretary of the Aero Club of America, and the pilot himself.

The barograph record will be exhaustively examined by air experts and mathematicians, to fix the official figures of the height. It was said that study of the record might result in placing the exact altitude achieved anywhere between 30,400 and 31,000 feet.

In one of its early tests it hung up a new record for speed—160 miles per hour, and upon another occasion it broke the climbing record by attaining a height of 16,000 feet in ten minutes. It has a wing span of 32 feet ½ inch and a total supporting surface of 309 square feet. Its overall dimensions are: Width, 32 feet; length, 23 feet 3 inches; height, 9 feet 10½ inches. The machine weighs, empty, approximately 1,900 pounds and carries a useful load of approximately 1,000 pounds. Its minimum speed is 58 miles per hour and its maximum range at economical speed is about 550 miles. The fuselage is streamlined throughout, presenting an almost continuous contour.

It is equipped with one of the new Curtiss twelve 400 horsepower motors, a complete description of which appeared in the February 3 issue of Aerial Age. This is a twelve-cylinder motor with a gasoline consumption of 0.55 pounds per brake horsepower and an oil consumption of 0.03 pounds per brake horsepower. The weight without oil or water is 720 pounds—almost one-quarter less than any other 400 horsepower motor. It has a 4½-inch bore of a 6-inch stroke. In the altitude flight 58 gallons of gasoline and 6 gallons of oil were used.

Roland Rohlfs, chief test pilot for the Curtiss Engineering Corporation, at the start of the flight in which he reached an altitude of 30,700 feet

Spad Flies 259 Miles in 110 Minutes

Mount Clemens, Mich.—Major Reed Chambers made a fast flight from Dayton to Selfridge Field in a Hispano-motored Spad, Model 13. The distance of 259 miles was covered in 110 minutes at an average of 141 miles an hour.

Prize for Around-the-World Flight

Hoquam, Wash.—Deeds to 1,000 acres of Gray's Harbor land, lying within what it has been hoped for years will prove an oil belt, are to be placed in a local bank as a reward for the aviator who first encircles the globe. George J. Hibbard, a Seattle attorney, makes the offer, and has set the time limit for winning the land at August 1, 1920.

Thomas-Morse Biplane in 35-Mile Glide

Ithaca, N. Y.—On August 2, accomplishing the longest glide on record, "Rex" Marshall attained an altitude of 17,000 feet, shut off the engine of his Thomas-Morse machine at the northern end of Cayuga Lake and glided thirty-five miles to this city, renewing his power at an altitude of 6,000 feet. Twenty-two miles is said to be the former record.

Supercharger Sets High Altitude Speed Record

Dayton, Ohio.—Major R. W. Schroeder, army aviator, on August 2, set a new world's record for high altitudes, it is claimed, when he flew at a rate of 137 miles an hour at a height of 18,400 feet. He used a two-seated Lepere biplane, designed by Captain Lepere of the French army. It was equipped with a twelve-cylinder Liberty motor and a supercharger. Lieutenant G. W. Elfey, expert aeronautic observer, was a passenger.

According to Captain B. G. Patterson, this development will have a marked effect on aerial navigation, because it will enable a pilot to fly at full speed and full power above the storm zone. It will also be potent in trans-oceanic flights and would make easy non-stop trips between New York and Chicago, regardless of weather conditions.

The supercharger is an attachment consisting of a gas turbine and centrifugal compressor, deriving its power from the

The Curtiss "Wasp" Triplane with which Roland Rholfs established a new official World's Altitude Record of 30,700 feet. Machine has a span of 32 feet, is 23 feet long, and weighs 1900 lbs. The engine is a Curtiss "12" rated at 400 H. P.

red-hot exhaust gases of the motor. It feeds the compressed air into the carburetor at the same pressure as at sea level, so there is no lack of oxygen regardless of altitude.

Hydro-Aeroplane Saves Drowning Swimmer

Patchogue, L. I.—W. D. Walton, who has been piloting a hydro-aeroplane in this vicinity, took part in the first hydro-aeroplane rescue since the war. While tuning up his plane for a flight his attention was called to a group struggling about an upturned boat, just discernable in the waters of the bay.

Half an hour later Mr. Walton returned with two dripping passengers, Miss Grace Flaherty of Laurel Hill, N. J., and H. V. Fajans of New York. A sailboat following behind bore a third moistened person, J. Stuart Blackton, Jr., son of the New York yachtsman and motion picture producer.

110 Minute Flight from Washington to New York

Washington. — Washington to New York by aeroplane in less than two hours was reported to the Air Service on July 29. Pilot Lieutenant Patrick H. Logan, with a passenger, Major William Conant, covered the 200 miles to Hazelhurst Field, L. I., in 110 minutes, averaging approximately 110 miles an hour.

Among the reports from various air stations received is one from Park Field, Tenn., showing a speed of 120 miles an hour, or two miles a minute for a distance of 160 miles. Pilot Lieutenant J. S. Marriott made the flight in a De Haviland four, carrying a passenger from Park Field to Jackson, Tenn., and return.

Passport Required for Flights to Cuba

Washington, D. C.—Passports are required for flights to foreign countries from American territory, as for instance, between the United States and Cuba. Section G. O. No. 76, W. D., Jan. 26, 1917, has been modified to include transportation to foreign countries by aeroplane as well as ships.

Pasadena Establishes Municipal Landing Field

Pasadena, Cal.—Pasadena has established a municipal landing field near the Altadena Country Club covering sixty acres. It has all the equipment of a first-class landing field.

Yakima, Washington, Has Up-to-Date Landing Field

Spokane, Wash.—The civilian aviators of Yakima, Wash., have added that city to the list of cities which have up to date aeroplane landing grounds. The Commercial Club obtained permission to use the acreage belonging to the Northern Pacific near the city limits as a site. The field will be properly marked and improved. Ernest Schneider, owner of a plane at Yakima, says he will erect a hangar on it. The club is to pay $10 yearly rental and the taxes for the use of the place.

Lieut. R. P. Parshall, Yakima aviator, is planning a flight around Mount Adams. He will carry as a passenger on the flight, which is under the auspices of the Commercial Club, C. E. Rusk, who has frequently climbed the mountain and been a leader in efforts to have it made a part of the proposed Yakima national park. Mr. Rusk is to be given an opportunity to take the first pictures from a plane of the mountain. The trip will require two days, one being taken in a preliminary flight to Glenwood.

Seeks to Prevent Flights Over Ranch

Kansas City.—Whether a property owner is also owner of the air above his land is to be determined through a court action brought by Frederick Hoenemann, a farmer. He seeks to restrain a company owning aeroplanes from using the air above his farm.

Hoenemann contends that the sight of the machines and the noise of their engine disturb the livestock.

From left to right: A. L. Allan, Curtiss pilot; E. L. Ovington, President of the Curtiss Flying Station, Atlantic City, and N. B. Stratton, N. W. Moore, J. W. Forse, Vice-President, Treasurer and Secretary of the Curtiss Aeroplane and Motor Co., respectively, at Atlantic City Flying Station

LePere Makes Record Flight in Florida

In a LePere, flying at an altitude of 6,000 feet, Lieutenant J. D. Corkille, with Sergeant J. R. Cook, made a flight from Arcadia to Daytona Beach on August 1, a distance of 186 miles, in 75 minutes, rate 148.8 miles per hour.

Lieutenant R. H. Smith, pilot in a De-Haviland 4, made a flight from Arcadia to Jacksonville, 265 miles, in 127 minutes, at an elevation of 5,000 feet. A new record for Florida. Passengers: Lieutenants W. L. Williams and R. J. Johnson.

Air Service Congratulates Wright

Washington, D. C.—The following telegram was sent by the Air Service to Orville Wright on July 30:

"The congratulations of the Air Service are extended to you on the tenth anniversary of the delivery of the first aeroplane to the Government of the United States, first in the world to acquire a dynamic air craft. The Air Service appreciates to the full the ever increasing debt owed by mankind to the Wright Brothers, whose foresight, indefatigable research and practicable application have aided the world progress through the invention of a new means of communication.

"MENOHER."

It will be recalled that ten years ago, on the 30th of July, the United States acquired the first aeroplane. This Government was the first in the world to be the possessor of an aeroplane, but had, however, no pilots. Later in the season the following American Army officers were taught to fly by Wilbur Wright: 1st Lieut. Frank P. Lahm, now Colonel, and 1st Lieut. B. D. Foulois, now Brigadier-General.

On July 30, 1909, Orville Wright and B. D. Foulois together made the second and final flight with the Wright machine contracted for by the Government the year before. This was a cross-country trip of five miles in each direction with and against the wind. The speed made was 42 miles an hour. On July 27 the endurance test of one hour was made in a flight which totaled 72 minutes, with 1st Lieut. Frank P. Lahm. Lieut. Lahm has the distinction of being the first American Army officer to fly.

While the Wright Brothers were negotiating in foreign countries for the sale of patent rights, they were communicated with by the United States Government, and in the winter of 1907 the Chief Signal Officer, General James Allen, advertised for bids for an aeroplane. Of 22 bids three were accepted. The Wright Brothers were the only ones to deliver a machine. In September, 1908, official demonstrating flights were begun at Fort Myer, near Washington, in the fulfillment of the contract, but the death of 1st Lieut. Thos. E. Selfridge, passenger, and the accident to Orville Wright, the pilot of the machine, postponed flights until 1909. Lieut. Selfridge was the first man in the world to be killed by a power-driven aeroplane.

The contract price of the machine was $25,000. The maximum speed demanded was 40 miles an hour, with a bonus of 10 per cent for each mile per hour in addition. The Wrights received $30.000 for a speed of 42 miles per hour. This was paid out of the funds of the Board of Ordnance and Fortification.

Travellers Company Starts New York-Atlantic City Air Transport Service

An air line carrying passengers between New York and Atlantic City, the first of its kind in this country, was inaugurated on July 25 at 11 A. M., when a flying boat with glassed-in body left the Hudson River at Ninety-sixth Street, on the 105-mile trip down the Jersey coast.

The flying boats are operated by the Travellers Company, composed of three young aviators who spent several hundred hours in the air in the British or American air service. The "limousine" flying boats are of 150 horse-power, have a speed of 75 miles an hour and can carry two or three passengers besides the pilot. Bookings will be made from the Waldorf, McAlpin and Claridge hotels, and passengers will go to the Hudson River by automobile from the hotels. The fare is $100 each way, and passengers are allowed thirty-five pounds of baggage.

The seaplane, according to the prepared schedule, will leave New York at 11 A. M. and arrive in Atlantic City at 12:30 P. M. The return trip will start at 3 P. M., and the Hudson should be reached by 4:30 P. M. Tests made on several days show that this schedule can be maintained, it is stated. The pilots are Robert B. Hewitt and Charles Todd Seims, and the passenger agent is C. Nicholas Reinhardt.

Zenith Increases Capitalization

Detroit, Mich.—The Zenith Carburetor Co. of Detroit has increased its capitalization from $40,000 to $320,000, of which $180,000 has been taken up by its present stockholders. The balance will not be issued at present. The real estate, buildings and other assets owned by the French corporation of the Zenith Company will be purchased with the new money.

Aircraft Materials Opens Chicago Branch

New York, N. Y.—The Aircraft Material and Equipment Corporation of New York has opened a branch office in Chicago in the Westminster Building. An additional branch will be opened in San Francisco, it was announced by M. W. Hanks, president of the corporation. The company carries spares for Canadian training planes.

Electric Tools for the Aircraft Industry

Baltimore, Md.—The Black & Decker Mfg. Co. of this city have prepared a handsome and comprehensive catalog describing their line of electric drills, air compressors and valve grinders. These tools are of the well-known standard quality of this company, and are of interest to the aircraft industry in connection with construction and repair of motors and maintenance of tire pressure.

Air Service to Sell Unserviceable Planes for Instruction Purposes

Washington, D. C.—According to an announcement from the office of the Director of the Air Service, the Air Service has an accumulation of miscellaneous aeroplane motors and unserviceable aeroplanes, which were used for instruction purposes at the various training camps and schools. It has been decided to offer these motors and aeroplanes to all colleges and schools desiring to teach aeronautical engineering, and prices have been fixed commensurate with their value for this purpose.

Although the motors are unserviceable for flying, all moving parts are complete. The prices range from $250 for Liberty and Hispano-Suiza engines to $75 for Lawrence engines. Le Rhone, Hall Scott, Mercedes, Thomas-Morse, Gnome, Renault, Clerget, and Sturtevant engines are included in the sale.

Glenn Martin R, Standard J-1, De Haviland and Thomas-Morse aeroplanes, without motors and instruments and unserviceable for flying are being sold for $250.

Pan-American Aircraft Co. Carrying Passengers in Pennsylvania

Norristown, Pa.—The Pan-American Aircraft Co. of this city is now carrying on a passenger carrying and exhibition business in Pennsylvania. Their present equipment consists of several Curtiss biplanes. Mr. Russel Brownback, formerly an officer in the infantry, is president of the company. Mr. Alfred Wainwright, vice-president, was in charge of machine-gun assembly for the Air Service during the war. The secretary and treasurer of the company, Mr. Howard R. Watt, was officer in charge of salvage at the aviation repair base at Dallas, Texas. Mr. Harry L. Brownbeck, chief engineer, served the Bureau of Aircraft Production in several capacities, including that of special representative of the Bureau in a tour of inspection of European aircraft factories.

The company had definite plans for expansion and will undertake the construction of aircraft in the near future.

Largest Shipment of Commercial Planes Made to New York

The largest commercial shipment of aeroplanes ever received in New York arrived recently when a trainload of machines reached here from Taylor Field, Montgomery, Ala., for the Curtiss Aeroplane and Motor Corporation. They will be assembled at Roosevelt Field, L. I., one of the concentration points for the distribution of planes purchased from the Government by the Curtiss Company. The shipment was made by express and consisted of thirty planes which have been sold to private purchasers who will use them for exhibition, passenger-carrying and pleasure-flying. They are the JN type, used by the American and Canadian governments in training army aviators. Another large shipment is now being made to Wilbur Wright Field, Dayton, Ohio, consisting of 40 machines. Since the purchase of machines from the Government the Curtiss Company has disposed of nearly 500 planes, which are now in operation in various parts of the United States. The Curtiss Company is establishing service stations at all of the larger concentration points and each machine that has been in use is being thoroughly overhauled and tested before it is allowed to be delivered to the customer.

British Aircraft Linen to Be Sold in U. S.

About 8,000,000 yards of the 43,000,000-yard purchase of aircraft linen which Leonard J. Martin recently made of the British Government will be sold in the United States to large and small purchasers. No effort is to be made to dye or bleach the material.

Canadian Firm Develops New Alloy

Montreal, Canada.—The Shawinigan Electro-Metals Co. of Montreal is said to have developed a new magnesium alloy particularly adapted to aircraft use. It is stated that the new product has but two-thirds the weight of aluminum and is as strong as steel. It is particularly suitable for use in the construction of pistons and connecting rods of aircraft motors.

South America Purchasing Curtiss Planes

The first foreign shipment of aeroplanes since the war was made recently when the Curtiss Aeroplane and Motor Corporation sent two land machines of the JN type and one water machine of the Seagull three-passenger type to Rio de Janeiro. The shipment was made on the steamer Saint Bede of the Lamport and Holt line.

It is the advance guard of the mission which the Curtiss Company is sending to South America for the purpose of demonstrating American-made aeroplanes to the Latin-American governments, corporations and people.

Orton W. Hoover, one of the first and best-known pilots in the United States, left at the same time to set up the machines and to demonstrate them.

Another shipment will be made on the steamer Frankmere of the same line, to Beunos Ayres, in a few days. This will consist of four JN.'s and one Seagull.

C. W. Webster, South American sales representative of the Curtiss Company, will sail on August 23 on the steamer Vasari, taking with him two three-passenger Oriole land machines, the first purely commercial plane developed.

Lawrence Leon, another well-known pilot who trained many army fliers during the war, is already at Buenos Ayres.

Headquarters will be established at Rio de Janeiro and Buenos Ayres at first, but the mission plans to give demonstrations in all of the South American countries. James Honor and Roy Schneider, two Curtiss mechanicians, are accompanying the party.

The Bolivian government has already received a Curtiss Wasp—the type of machine in which Roland Rohlfs, Curtiss test pilot, recently established a new American altitude record. It is equipped with a Curtiss twelve 400 horsepower motor and with overhanging wings. It will be used for training purposes. The Wasp was built as a two-place fighting machine and has a speed record of 160 miles an hour and a climbing record of 16,000 feet in ten minutes. It is exceptionally adapted to work in high altitudes.

New Schedule for New York-Washington Aerial Mail

Through an arragnement made between the Air Mail Service, Postmaster Chance of Washington and Postmaster Patten of New York, a change has been made in the air mail schedule between New York and Washington by which the mail from New York and New England will reach Washington in time for the early afternoon delivery; and the mail from Washington and southern connections to New York will reach that city around 1 o'clock.

The air mail will hereafter leave New York at 8:40 A. M., arriving in Washington at 11 A. M. Operating on this schedule all New York City mail which reaches the postoffice too late for the midnight train for Washington and all New England mail reaching New York between midnight and 8 A. M. will be carried by aeroplane to Washington.

The mail aeroplane will leave Washington at 10 A. M. carrying Washington City mail and mail brought in by the Atlantic Coast Line and Seaboard Air Line and their connections from the South, the mail reaching New York about 1 o'clock for middle afternoon delivery.

The aeroplane left New York on the morning of July 30, under the new schedule at 8:45 with between 12,000 and 13,000 letters from New York and New England, arriving in Washington at 10:55 A. M. and was being distributed by 11:30 A. M.

"The New York and New England mail," said Postmaster Chance, "went out on the 12:20 P. M. city delivery. It is extremely gratifying to be thus able to give the Washington public the benefit of a service many hours earlier by this adjustment of the air mail schedule. The New England mail is advanced about 16 hours and all mail from New York left over from the midnight train is in time for the first afternoon delivery in Washington. Public appreciation of this improvement of the service finds expression in many commendations from people in Washington which I receive."

Alaska-Seattle Mail Route

From present indications it appears practically certain that the next eighteen months will see the establishment of the Alaska-Seattle Aerial Mail Service. The Post Office Department has promised the service to Alaska in 1920, and the post office appropriation bill expressly states that money appropriated may be used for an Alaska service. This is due directly to the joint efforts of W. E. Boeing and E. N. Gott of the Boeing Aeroplane Company, who have furnished the Post Office Department with charts, showing courses, distances, landing stations, where fuel could be obtained at present, and a general resume of all foreseen contingencies.

It is possible that this service may be obtained this coming year, if a large amount of enthusiasm should be made manifest by the people of Alaska to the Post Office Department. Chambers of commerce in Alaskan cities and business firms having an interest in the advancement of commercial relations in Alaska should petition the Post Office Department for the early establishment of this service.

As the time required to make the trip by seaplane is a daylight trip against four days by steamer, the possibilities of a commercial passenger and light express service are also very great. Such an opportunity will be quickly seized. An aerial service to Alaska can be maintained for at least eight months without interruption, and for the remaining four months, with certain delays due to weather conditions. Flying at an altitude of three thousand feet, an aviator can at any point along the route, in case of engine failure, glide down to protected water. Even this contingency is eliminated in the use of twin motored machines, such as are being used at present on the Paris-London route.

Thus, enthusiasm is all that is needed to start the Alaska-Seattle Aerial Mail Service.

Air Mail Pilot E. Hamilton Lee served as stunt flying instructor during war

Superintendent Appointed for Aerial Mail Station at San Francisco

San Francisco, Cal.—According to a statement appearing in the San Francisco *Bulletin*, an aerial mail service between New York and San Francisco will be in operation at no distant date.

A regularly established aerial mail service between San Francisco and Los Angeles and San Francisco and Seattle in the immediate future is assured.

An aerial mail service station, with hangars, supply, repair and machine shops, will be established and maintained in San Francisco.

In charge of the maintenance and operation of the Aerial Mail Service of the United States, already appointed to the position, will be a San Francisco man, Edward McGrath, chairman of the Postal Censorship Committee in New York during the war, just prior to which he was Assistant Superintendent of Railway Mails in Boston, and for many years was Superintendent of Railway Mails in San Francisco.

Aero Mail Pilots Receive Increase

Washington, D. C.—One of the terms of settlement of the aerial mail pilots' strike was an increase of pay by the granting of $3 per day allowance while aviators are on duty away from home.

The terms of settlement are reported to be as follows:

1. The pilots who were summarily dismissed because they refused to make an ascent in the face of dangerous weather were upheld, when the situation was made clear. One was reinstated.

2. The orders applying to airmail flights were amended, giving to the district manager or superintendent the say whether the conditions were right for flying, instead of ordering flights from Washington without knowledge of exact local conditions.

3. The pilots, whose salaries now run from $2,000 to $3,600 a year for their hazardous work, get a raise in salary, or rather an extra allowance of $3 a day while they are away from home.

1500 American Legion Posts Already Organized

According to a recent statement, already more than 1,500 posts of the American Legion have been organized. New York state leads with 130 posts. All men who wore the uniform for at least fifteen days between April 7, 1917, and November 11, 1918, are eligible to membership, unless they were conscientious objectors. National headquarters are in New York City. Lieut.-Col. Theodore Roosevelt, Col. Henry D. Lindsey and Col. Eric Fisher Wood.

THE IMBER SELF-SEALING GASOLINE TANK

By GEORGE F. McLAUGHLIN, A. M. E.

NUMEROUS attempts have been made to perfect a gasoline tank which would be proof against leakage in the event of being punctured and proof against fire when pierced by incendiary bullets or other projectiles. Before such a device was perfected for use in aircraft, approximately 75% of the fatalities could be directly attributed to the fact that the fuel tanks were pierced and the leaking gasoline became a source of danger. Mr. Jack Imber of London, England, undertook to study the requirements of a self-sealing tank and his researches led to some remarkable discoveries.

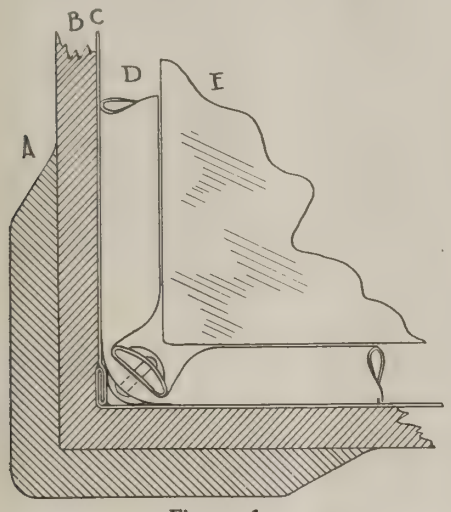

Figure 1

Detail of a corner of the Imber Self-Sealing Gasoline Tank. A—*Rubber reinforcing;* B—*Rubber covering;* C—*Outer shell or casing;* D—*Framework members;* E—*Baffle plate.*

A small bullet can inflict extensive damage when passing through a gasoline tank. In many cases it is found that an ordinary bullet will tear a hole six or eight inches in diameter in the side of the tank opposite to that through which the bullet enters. This phenomenon perplexed most of the inventors who were seeking a remedy to keep the gasoline from leaking from bullet holes. Most of the devices failed for either they were too heavy or some important detail of the structure was not properly disposed because of an unfamiliarity with the actual forces existing in a tank under such circumstances.

Before going on with a detailed description of the tank invented by Mr. Imber it might be well to present the theories upon which the invention is based. A bullet entering the fuel tank makes an aperture as large in diameter as the bullet itself. It leaves a clean hole which is easily sealed by the rubber covering. In emerging, however, a relatively large hole is torn in the metal. Investigation showed that the larger hole was due to the enormous pressure of fuel against the far side of the tank. Upon entering the tank the progress of the bullet is somewhat arrested by the liquid but in its travel through the tank the pressure of the liquid increases both in area and force from the point of entering to a distance of approximately 2'-6". Thus, when a bullet travels through a tank of large diameter its momentum is checked before it goes entirely through, while on the other hand in a tank of ordinary size it is found that up to a certain point the further one side wall is from the other, the larger will be the hole torn upon the exit of the bullet.

It was readily seen that the pressure generated in the tank would either have to be confined or released. Many inventors sought to confine the pressure but results showed that when the bullet made its exit the pressure sought exit through the aperature made by the bullet and in its effort to escape an enormous rupture is made in the tank.

Having acquired a knowledge of the action taking place in a gasoline tank when it is pierced Mr. Imber was in a position to seek a means of perfecting a tank to such a degree that not only would it prevent leaking when pierced but which would also prevent the escape of the liquid in the event of a bad crash. Tanks which had a small measure of success in stopping simple gasoline leakages utterly failed to retain the liquid when a machine crashed. It is this latter feature that specially commends itself to the present designers of commercial aircraft for it is well known that many crashes that in themselves do not result seriously are disastrous only because the tank was not constructed to withstand the strain of a damaging impact, with the result that fire follows.

Figure 3

Method of crossing the tubular members of the Imber tank framework and of securing them to one another with rivets

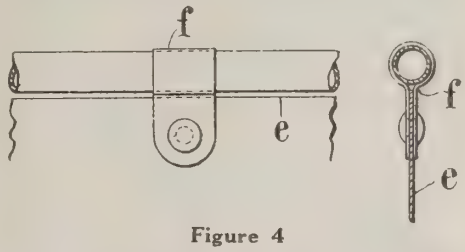

Figure 4

Clips used to secure baffle plates to the inner framework of the Imber tank

The Imber principle allows the air to escape by providing the tank with a resilient outer rubber covering so that when the inside pressure exceeds a certain point the tank yields and the rubber stretches out from the side of the tank under pressure. Naturally, the highest point on the stretched rubber covering is that through which the bullet makes exit and the rubber being stretched makes this point also the thinnest portion of the covering so that when the bullet leaves and the pressure is relieved the rubber goes back to its former shape completely closing up and sealing the bullet hole.

When the Imber tank made its appearance some experimenters suggested the use of angular section braces for framework and diaphragm or baffle plate supports. Failures resulted, due to the fact that when the metal brace was bent outward against the covering it required an equal amount of pressure from the outside covering to force the frame back in place and allow the rubber covering to assume its normal position. The aluminum tubing employed by Imber after being bent outward is easily brought back into place with a great deal less pressure than that required to bend it outward in the first place. The elasticity of the rubber covering is sufficient to force the bent tubular members back in place so that the bullet hole is closed but in cases where other inventors used angle frames, the rubber covering was torn by the unyielding metal.

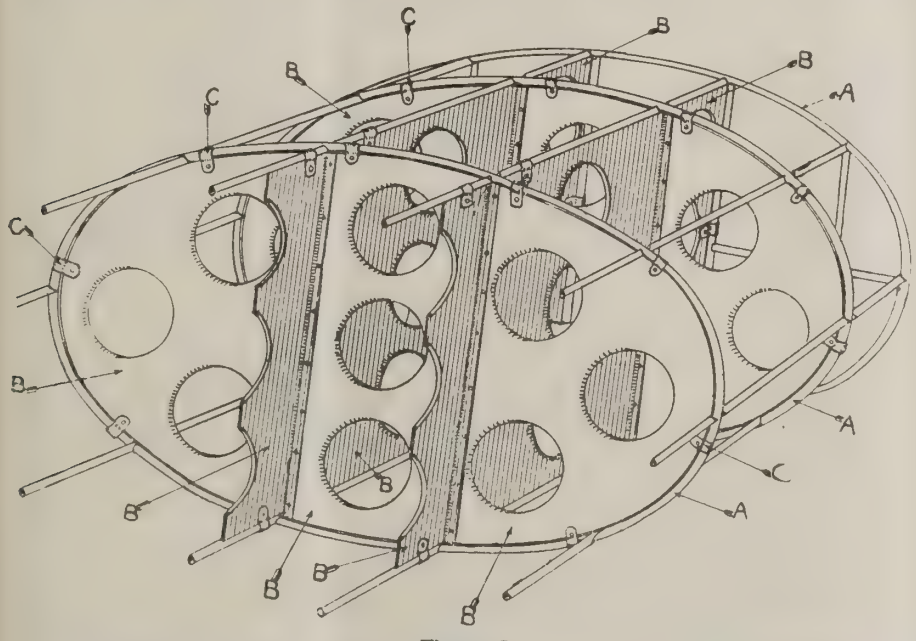

Figure 2

Diagrammatic sketch showing part of the inner framework of an Imber tank for the R. E. 8 aeroplane. One end elliptical framework is not shown in the drawing

Description of the Tank

The Imber tank is composed of three parts. The inside tubular aluminum framework (D-Figure 1) to which sheet aluminum baffle plates (E-Figure 1) are attached. The framework is adapted to fit within and conform to the shape of the shell. The second part of the tank consists of a metal shell (C-Figure 1) into which the baffle plate frame is inserted. The third part of the tank consists of an outside rubber covering (B-Figure 1) which surrounds the entire shell. The resilient or elastic covering returns to its seating against the framework in such a brief space of time that it is impossible for the contents to ignite in the event of the projectile being of an incendiary nature.

The tank is installed in the aeroplane by means of a cradle, in such a way that no rivets, bolts, etc., are used to secure it to the machine.

Framework and Baffles

The general arrangement of the internal cradle or framework and baffle plates is shown in Figure 2. The diagram shows an oval tank, but of course the principle is applicable to tanks of any shape or any size.

The framework is built up of aluminum tubing about 5/16" in diameter and 22 gage in thickness. The diameter and gage of material varies according to the size of the tank. Where the tubes cross one another they are held together by rivets as shown in Figure 3, or they may

Figure 5

A sweated or welded joint on the Imber tank

be welded together. Baffle plates are secured to the framework by means of aluminum clips as shown in Figure 4. In this figure, "e" shows the baffle plate and "f" shows the clip.

The entire framework together with the baffle plates is constructed so that no rivets or other means are used to hold it in place in the shell. It is imperative that the inner cradle be not fixed in any way to the metal shell.

The function of the framework is to form a backing against which the rubber covering may seat itself to form a self sealing covering.

Shell

The shell or casing is made of tinned steel. Other materials including copper were found to be inferior in some respects to the metal finally adopted. Tanks with a capacity of more than 38 gallons are made of number 28 gage tinned steel. Joints are formed as indicated in Figures 1 and 5. The joint is sweated, welded, or otherwise formed without the necessity for the employment of rivets or other members passing through the metal.

Covering

The outer covering is of specially prepared rubber which is put over the entire surface of the tank. The rubber is approximately ¼ of an inch in thickness. Edges of the tank are reinforced with an additional rubber strip ¼ inch thick vulcanized to the covering rubber. The entire tank is then vulcanized for about 75 minutes under a steam pressure of about 40 pounds per square inch.

Specifications require that the rubber covering shall fit closely to the metal shell of the tank but that after vulcanization there shall be no adhesion between the rubber and metal. Adhesion is prevented by chalking the adjacent surfaces of the metal and rubber before the vulcanizing processes.

Rubber is composed as follows:

Best smoked sheet (or other approved rubber)	92%
Magnesium Oxide	2%
Sulphur	6%

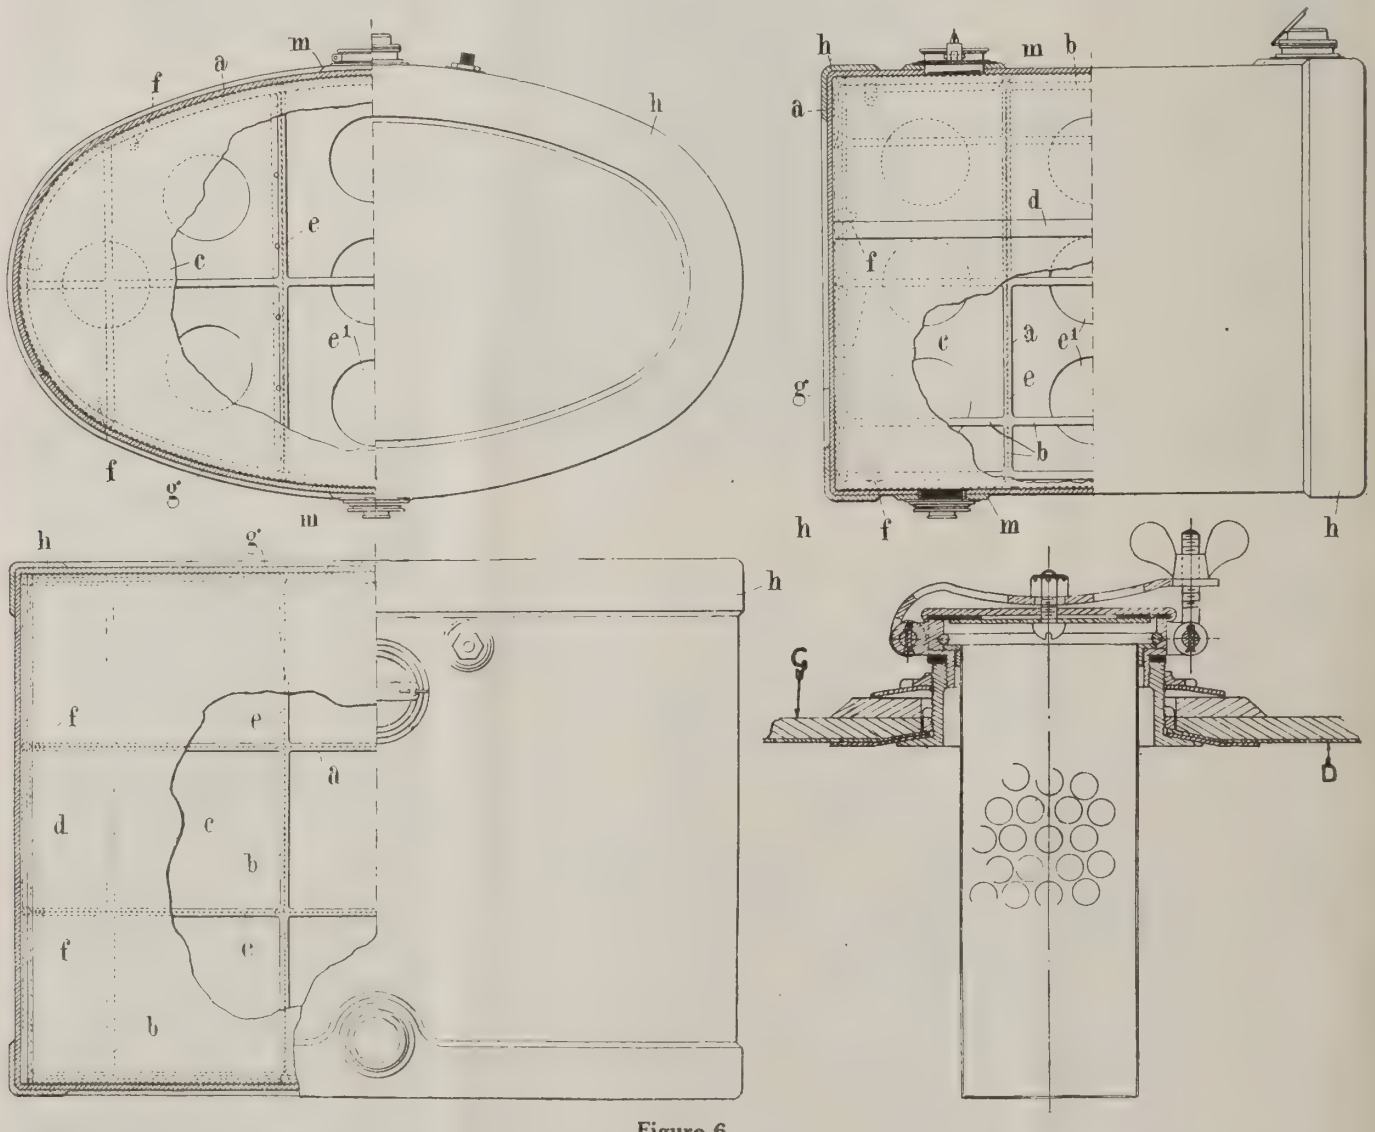

Figure 6

End and side elevations and plan of the Imber tank. Views are shown half in section. *a—Peripheral members conforming to the shape of finished tank;* b—*Members welded to one another to form a complete cradle;* c—*Outer shell or casing;* d—*welded joint (shown in Figure 5);* e—*Internal baffles or partions;* e1—*perforated baffles;* f—*Clip for securing baffles to frame (shown in Figure 4);* g—*Rubber covering;* h—*Rubber reinforcing;* m—*Rubber washer.* The lower right hand detail shows a section through the filler cap.

This is cured to the degree which results in the vulcanized covering satisfying the tests mentioned below. As a trial cure the following is suggested:

30 minutes rising to 40 pounds steam pressure.

65 to 75 minutes at 40 pounds steam pressure.

The quality of smoked sheet or other raw rubber is such that not more than six parts per cent of organic matter and sulphur can be extracted from the finallly vulcanized product after boiling it in a finely ground condition for eight hours with a six per cent solution of alcoholic potash.

The raw rubber compound is calendered into sheets and built up to the required thicknesses by doubling upon a calender. All traces of air are excluded from between various layers.

The vulcanized India rubber is equally and evenly cured throughout and under microscopic examination, is of homogeneous character, free from air holes, porosity and all other imperfections.

Where a sticking solution is used it consists of a solution in coal tar naphtha with the addition of a further four per cent weight of sulphur.

Method of Covering Tanks

In order to prevent blistering during vulcanization provision is made for the dispersal of any air which may be entrapped accidentally between the rubber sheet and the metal tank.

NOTE: A satisfactory method is to affix a series of strings or fabric tapes around the outer surfaces of the metal tank, with the ends of all strings or tapes projecting at the opening in the rubber cover at the fuel filling aperture. Extending not less than one inch beyond each line of the bevel and at least equal to half the thickness of the rubber which it covers.

Where distortion of the tank is found to occur, owing to shrinkage of the rubber curing cure, the compound sheet is shrunk, before building on to the tank, by immersion in

1—Boiling water, or

2—Steam at 1 to 5 pounds pressure.

The treatment should not continue for more than ten minutes.

When the compound sheet is shrunk before building on the tank, all adhering surfaces of seams and joints are roughened and given a sticking coat of the vulcanizing solution before being joined.

The covering is so devised that a minimum number of rubber joints is made.

Where ends are joined by bevel joints the length of the bevel is at least one inch and the joint is strengthened by a super-imposed strap of rubber.

Vulcanization

The rubber covering is vulcanized in position on the tank by steam heat and either the "open-cure" or "wrapped" processes is used. The complete rubber covering is vulcanized in one operation.

When the "wrapped" process is employed great care is taken that the binding is so adjusted as to prevent distortion of the metal tank, and thinning of the rubber cover at points of extra pressure.

During vulcanization the apertures of the tank are left open to permit free entry and circulation of the steam and to equalize the pressure inside and outside the tank.

Upon completion of vulcanization all joints and seams are firm, homogeneous, free from blisters and loose edges and resist stripping by hand.

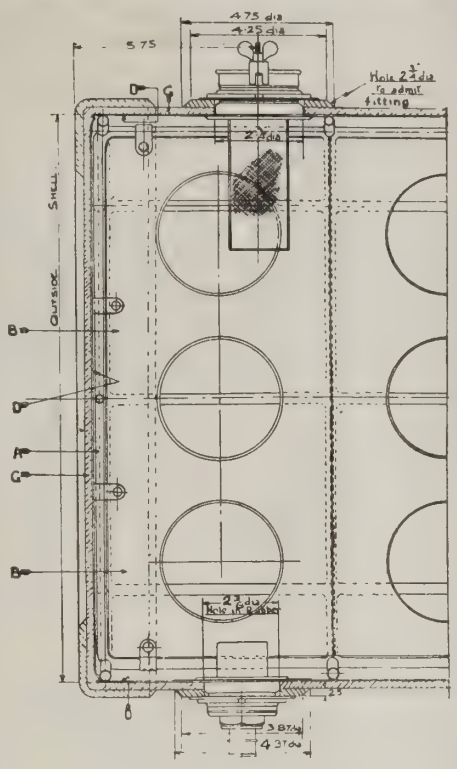

Figure 7

Side section of one half of the Imber tank for the R. E. 8 aeroplane. The cradle comprises four substantially elliptical frameworks, such as A, two of which are braced by horizontal and vertical tubing. The baffle plates (B) are connected to the tubing by clips (C) and to each other by ordinary rivetted joints. The baffling effect obtained is thus identical with that of a standard R. E. 8 main tank while fulfilling the condition that the baffles are nowhere attached to the tank lining (D). G indicates the outer rubber covering

Tests

With each group of tanks vulcanized a test piece is given treatment at the same time. This sample is prepared from the batch of rubber compound sheet which is used to cover the tanks.

1. Where an "open cure" is employed the piece of compound sheet is 0.25 inches thick and at least 8 inches square.

2. Where the "wrapped" process is used, the compound is made up on a mandril in the form of a tube having a wall thickness of 0.25", a length of 8 inches and an internal diameter of at least 2⅝", wrapped before vulcanization in the same way as the tank.

The sample is vulcanized in the same way and at the same time as the India rubber covering upon the tank and it is marked with an identification number corresponding with that upon the tank which it represents.

1. For chemical tests the combined Sulphur by difference of the sample should be between 3% and 4.5%.

2. A piece of sheet of 0.25" x 0.5 x 1" immersed in gasoline at a temperature of 15.5°C., for a period of five minutes should increase in volume within a minimum of 8% and a maximum of 12%.

For physical tests a rectangular piece of vulcanized sheet 0.25" thick and 0.5" wide is stretched to three times its original length for 24 hours and it should regain within six hours after release its original length within plus 2.75 per cent.

Final Test

After vulcanization and completion of the covering, an internal pressure of one pound per square inch is applied to the finished tank; at the end of a period of 15 minutes there should be no indication of leakage as measured by loss of pressure.

Fittings

In order to provide for the greater security of the tank against leakage, all fittings are provided with double seatings so that in the event of one joint giving away there will still be a second joint to prevent leakage.

In one convenient form of fitting the desired effect is obtained by having a flange internally threaded bush sweated upon the inside of the casing and surrounding the aperature for the fitting. Into this is screwed a second bush or sleeve carrying the fitting which makes with the first mentioned member a joint by means of fibre or packing. This second bush or sleeve projects beyond the rubber covering of the tank and is surrounded by a metal washer which is forced into close contact with the exterior of such covering by means of a flange upon such sleeve so as to form a second joint or seating for the fitting. The inner bush is so constructed and arranged that it is practically flush with the inner surface of the metal shell.

No part of the fitting is allowed to project into the tank in a manner which would prevent the cradle from being slipped into the tank.

A specially designed filler cap is provided, as shown in one of the diagrams of Figure 6. The cap is held securely in place by means of a single wing nut and flat spring. The arrangement has been found to be very simple in operation for there are no parts to become detached and it is easily manipulated by inexperienced mechanics, without danger of damaging the tank.

The diagram shows the outer flange or collar in position before being screwed down. By screwing down the collar the outer edges of the washer press into the rubber reinforcing strip, making the joint tight and leak proof. In the diagram, G shows the rubber covering, and E, the metal shell.

Retention of Fuel in a Crash

Besides eliminating leakages due to bullet holes, the Imber tank is able to retain its liquid when subjected to a severe blow from the exterior. Minor shocks are, of course, taken care of by the rubber covering, but when a hard blow is struck the internal construction gives. While the framework is strong enough to give adequate bracing to the tank under ordinary usages, it is purposely made collapsible upon the application of a blow likely to cause a puncture. In the case of a landing in which a smash occurs, the rubber covering retains the gasoline no matter how badly the tank may have been battered. While the framework of an aircraft may crumple and strike forcefully against the tank or the tank strike the ground, the result will merely be a distortion of the shape of the tank, thereby minimizing the danger of fire from the inflammable liquid that otherwise would have been sprayed about the wreckage.

A feature making the use of the Imber tank unlimited in its application is the fact that it can be made of any shape or size and not only is it suitable for use on aeroplanes and dirigibles, but it is also of great value for storage purposes on the ground.

THE ZEITLIN AERO ENGINE

WE have just secured the details concerning the design and construction of an interesting new aero engine, the invention of Mr. Joseph Zeitlin, of London, England. The engraving, Fig. 1, represents Mr. Zeitlin's first engine. The general arrangement, given in Fig. 2, illustrates the design of a nine-cylinder engine on the same general lines as the first seven-cylinder example, but embodying certain minor, though important modifications, introduced as a result of experience with the preliminary engine.

The new engine resembles certain other aero engines in so far as it is of the four-stroke cycle, rotary type. Its fundamental point of difference consists in this, that the piston stroke is not of uniform length in each of the four movements constituting a complete cycle. What happens in the case of an engine having a working stroke of 181 mm. can best be explained by means of the simple diagram given in Fig. 3. After the downward working stroke of 181 mm., the piston executes an upward exhaust stroke of 203.5 mm. The extra 22.5 mm. of movement brings the top of the piston almost up against the face of the cylinder head, and very thoroughly clears out the products of combustion from the cylinder. The exhaust takes place through a mechanically operated valve situated at the center of the cylinder head. The succeeding downward suction stroke is 226 mm. in length. The extra 22.5 mm. of motion in this stroke results in the piston overshooting a port B in the cylinder wall near its foot, and, as a result, explosive mixture passes from the crank case into the cylinder interior. During the suction stroke the exhaust valve is held open for some distance A, so that a suitable proportion of air for the combustion of the explosive mixture may be drawn into the cylinder. The succeeding compression stroke of 203.5 mm. stops about 23 mm. or so from the cylinder head, so as to afford a proper amount of compression space, and leave the piston in the correct position to commence the working stroke. The working stroke, it will be gathered, stops short just before the inlet port B would be uncovered.

It will be seen then that the piston, in addition to its ordinary reciprocation through 181 mm., performs a harmonic motion through a range of 22.5 mm. This result is achieved by coupling the connecting rod not straight on to the crank pin, but on to an eccentric bush of 15.907 mm. throw surrounding the crank pin, and by driving this bush round the crank pin as axis, in the same direction as the engine and at one-half the engine speed. The crank throw is 101.75 mm.

To understand how this arrangement gives the required motion to the piston, the diagrams given in Fig. 4 will be found of assistance. For simplicity we have here represented the idea applied to an ordinary fixed-cylinder, rotating-crank shaft engine. At the commencement of the working stroke, the crank is at O A and the center of the eccentric at B, the angle O A B being 45 deg. Were the eccentric fixed rigidly to the crank pin then at the end of the working stroke its center would be on the line C D. As it is, during the half revolution of the crank, the eccentric is driven round the crank pin through one-quarter of a revolution in the direction of the arrow marked on it, so that at the end of the working stroke the center of the eccentric is at E. The effective length of the working stroke is thus not A C but B E, or two cranks minus twice the horizontal projection of the eccentricity A B or, in symbols, $2r - 2p$. During the exhaust stroke the eccentric makes a further quarter revolution so that the effective length of the exhaust stroke is F G, or $2r - p + p = 2r$. Similarly, the effective length of the suction stroke is H J or $2r + 2p$, and of the compression stroke K L or $2r + p - p = 2gr$. The throw A B of the excentric being 15.907 mm., and the angle O A B 45 deg., the horizontal projection p measures 11.25 mm. The crank radius being 101.75 mm., the lengths of the strokes are as follows: Working stroke, 203.5 — 22.5 = 181 mm.; exhaust stroke, 203.5 mm.; suction stroke, 203.5 + 22.5 = 226 mm.; compression stroke, 203.5 mm.

In Fig. 4 it is to be noted we have shown the eccentric as rotating in the *opposite* direction to the crank shaft. So far as the mere motion of the piston is concerned an exactly similar result is obtained by rotating eccentric and crank shaft in the *same* direction, as will be made clear by a study of Fig. 5. Let us consider the difference between these two arrangements as applied in a rotary engine of Mr. Zeitlin's actual type. In Figs. 6 and 7 we illustrate diagrammatically what occurs between the eccentric and the connecting-rod big end during the working or explosion stroke when respectively the eccentric is made to rotate oppositely to and in the same direction as the cylinders. In Fig. 6, A is supposed to be the crank, B the eccentric, and C the connecting-rod. When the piston is at its inner dead center let us mark the eccentric at D and the connecting-rod bush at E. Imagine for the moment that the eccentric is fixed rigidly to the crank pin, and that the engine is turned through half a revolution. The point D remains stationary at F, but the point E moves round to G through the arc F H G. The design of the engine, however, requires that the eccentric when the piston is at its outer dead centre should be in the position shown in the third sketch. In other words, the eccentric has to be rotated on the crank pin, so that the point D may move from J to K. This is achieved by turning the eccentric clockwise through a right angle. The total relative movement between the eccentric and the connecting-rod bush is thus the arc K J L.

In the alternative arrangement illustrated in Fig. 7, the motion of the point E is as before through the arc F H G. But this time the motion of the point D is anti-clockwise from J to K. Thus the net relative motion of the two points is through the small arc K M L. It will be seen then that the rubbing speed in the first case is three times as great as in the second. The rate of wear is correspondingly greater. In his first experimental engine Mr. Zeitlin adopted opposed rotations, but the important practical consideration we have just explained has led him in his subsequent designs to abandon it in preference for rotations in the same direction.

In the earlier arrangement the bush A, Fig. 8, surrounding the crank pin and carrying the eccentrics was rotated by a

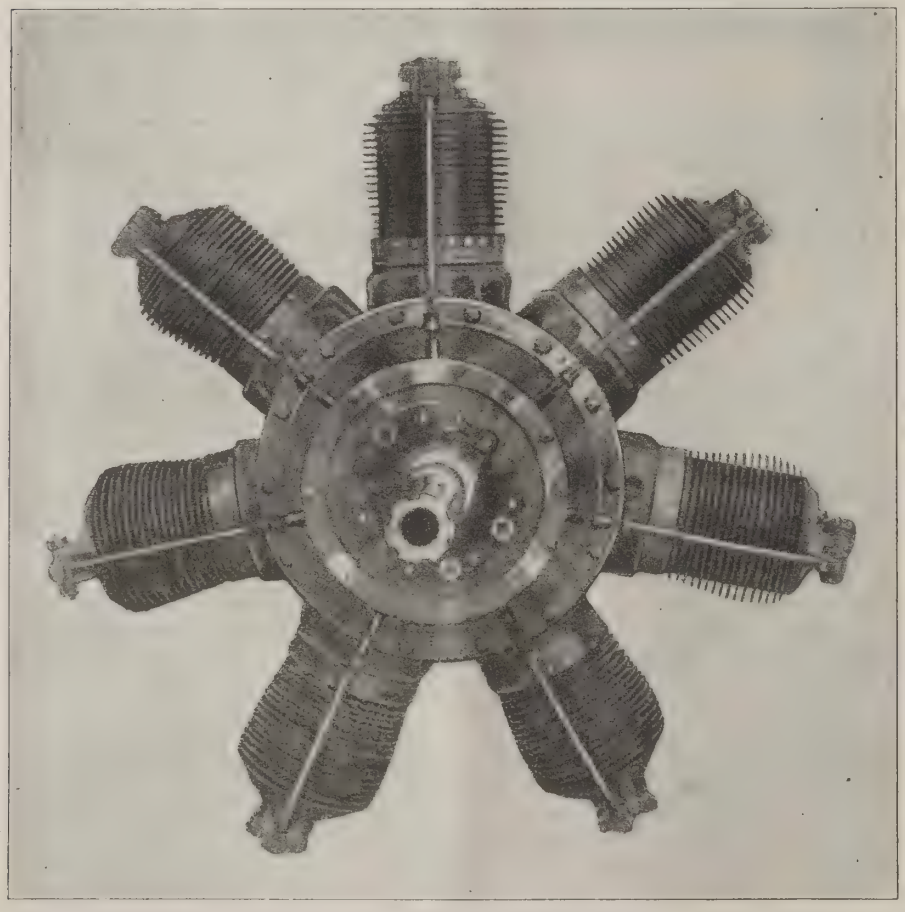

Figure 1
The Zeitlin Aero Engine

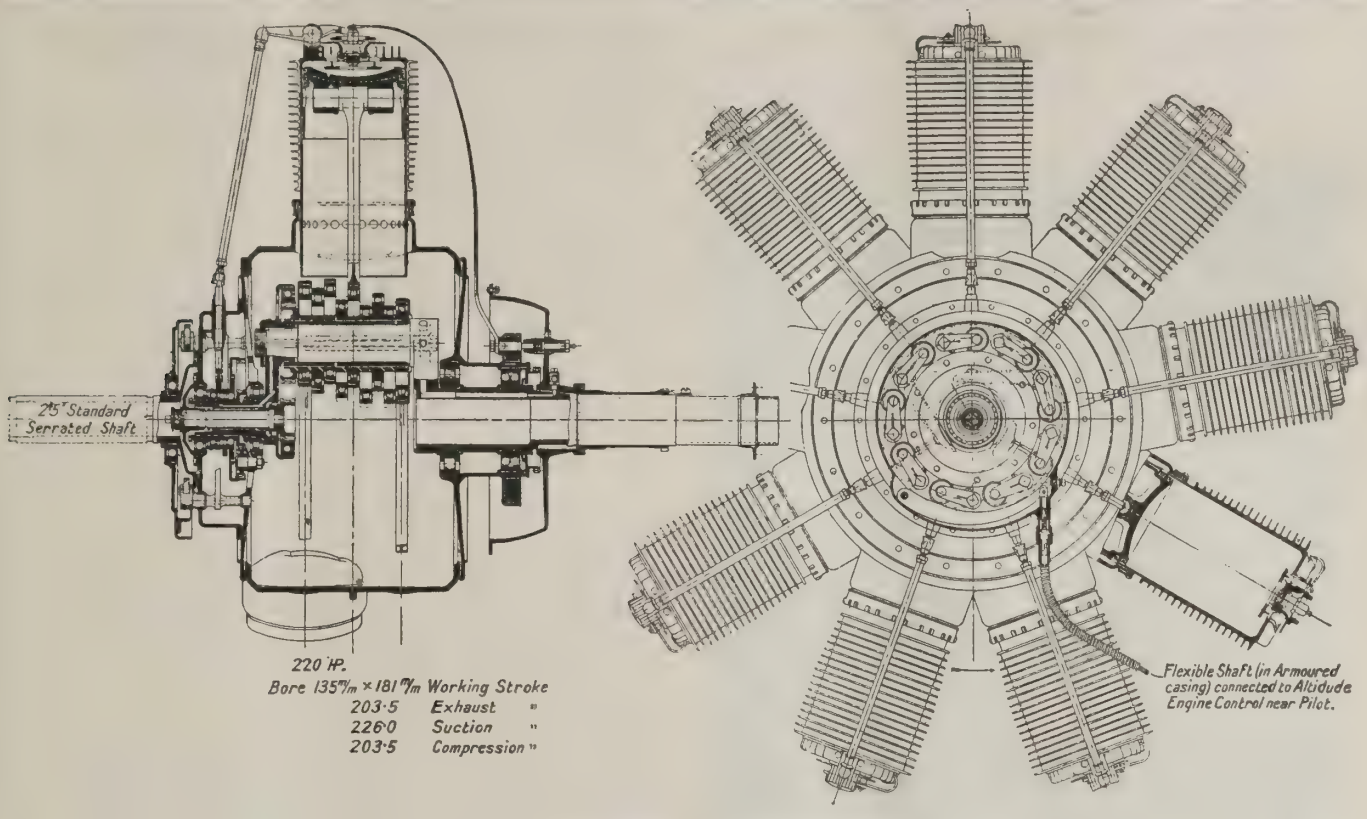

Fig. 2—NINE-CYLINDER 220 HORSE-POWER ENGINE

pair of gear wheels B C, the first fixed to the bush, and the second journalled on the crank shaft, but fixed to and rotating with the crank case. In the later arrangement the obvious method of driving the bush D is to employ two wheels E F connected by an idler G to give the required reversal of direction of rotation. It was found difficult, however, to get a three-wheeled 2-to-1 reduction train into the space available, and for this and other reasons Mr. Zeitlin evolved the patented system shown diagrammatically in Fig. 9. In this system two wheels A B of a 2-to-1 ratio are arranged inside an internally geared ring C. The wheel B is united to the crank pin sleeve D which carries the eccentrics. The spindle of the wheel A is fixed to the rotating crank case E in line with the extension piece F carrying the propeller hub. The ring C is mounted on balls within a flanged disc G. This disc forms one web of the crank. It is bolted to the crank pin and at H provides one of the journals whereon the crank case rotates. The journal H is bored to receive the spindle of the wheel A. It will be seen that the sleeve D is thus driven in the same direction as the crank case rotates in, and that, in fact, the ring C is exactly equivalent to the idler pinion shown in Fig. 8.

There is another substantial advantage, besides that of reduced wear, involved in driving the eccentrics and the cylinders in the same rather than in opposite directions. This advantage is concerned with the nature of the stresses thrown upon the teeth of the gearing driving the eccentric bush. Without going into an elaborate demonstration, we can only say that with the earlier arrangement the bending stress on the teeth of the wheel is reversed once every half revolution, the average reverse stress being practically equal to the average direct stress. With the later arrangement this serious practical disadvantage is avoided.

Turning now to the general drawing, it will be understood that the side-by-side disposition of the nine eccentrics on the crank pin requires the nine cylinders to be correspondingly staggered round the crank case. It seems hardly possible to combine the Zeitlin eccentric crank arrangement with the co-planar cylinder disposition found in the master connecting-rod and other types of rotary aero motors. Nevertheless, Mr. Zeitlin has succeeded in placing the cylinders in such a way that lack of balance arising from their being staggered has been eliminated. Starting with the left-hand eccentric as No. 1, the eccentrics are associated with the cylinders in the following order:—

Eccentric, No. 1 2 3 4 5 6 7 8 9
Cylinder, No. 1 8 3 6 5 4 7 2 9

The order of firing in the cylinders follows the sequence usual in rotary aero engines, namely, 1, 3, 5, 7, 9, 2, 4, 6, 8.

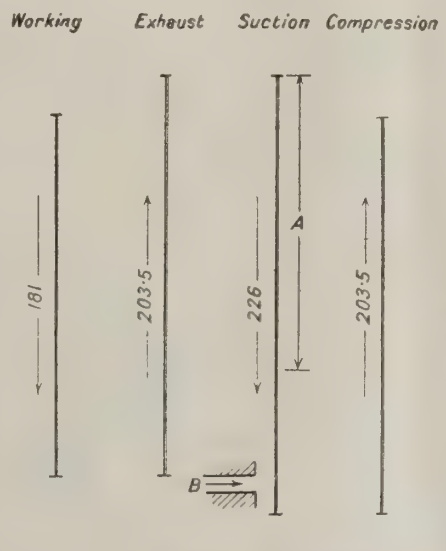

Fig. 3—LENGTHS OF STROKES

The form of the central exhaust valve should be noted. It is in the nature of a ring which closes and opens an annular port in the cylinder head. The sparking plug is disposed at the center of the ring, the idea being that the exhaust passing into the annular port round the inner and outer circumferences of the valve shall not cause any deposit in the neighborhood of the sparking plug. In our presence one of the cylinders of the first engine was removed after a run. It was found that whilst the cylinder head beyond the larger radius of the exhaust valve was coated with oil, the surface within the ring was clean.

The electrical connection between the sparking plug and the distributing ring is a flat strip of stream-lined duralumin formed with an eye at one end to clip on to a button at the top of the sparking plug. The other end of this lead is fixed to the distributing ring by means of a stud and spring washer, constituting a self-tightening connection. The object of these details is to permit the ready removal of the cylinder in the least possible time. To effect this removal, the duralumin lead is first pressed slightly towards the cylinder until its eye is released from the plug button. It is then pushed backward—into the plane of the paper, as it were, in the general arrangement drawing—so as to clear the cylinder. It now remains only to free the large nut that holds the cylinder within the screwed gland in the crank case. With this nut released, the whole cylinder can be lifted away, for, as usual, the valve rod and tappet rod are not mechanically connected. It will be noticed that the cylinder body is made in two parts, the inner part, the cylinder proper, being a separate entity from the outer part, carrying the radiating fins. The latter part is made in aluminium.

The method of operating the exhaust valves, and the altitude control associated with it, is one of the most interesting

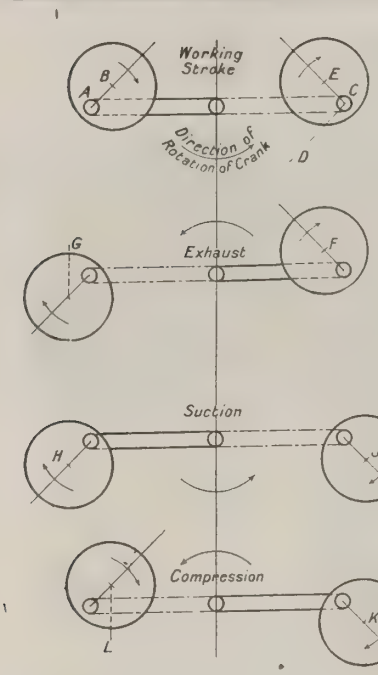

Fig. 4

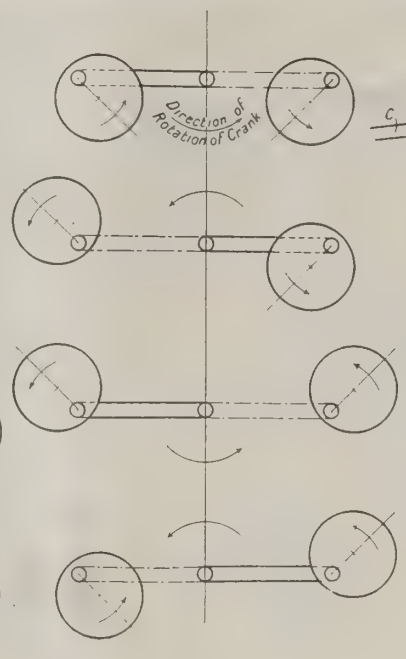

Fig. 5

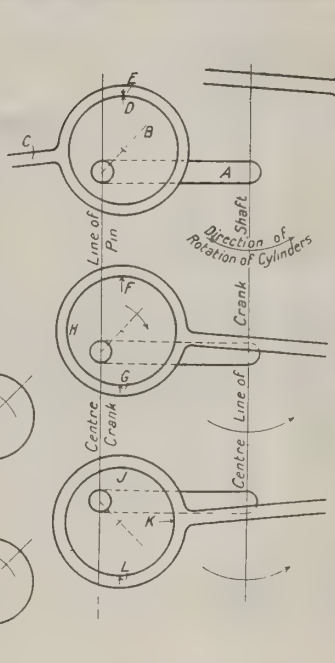

Fig. 6

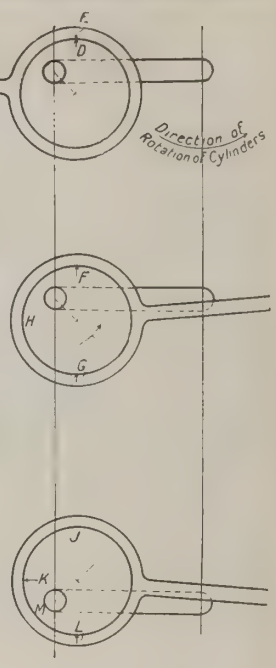

Fig. 7

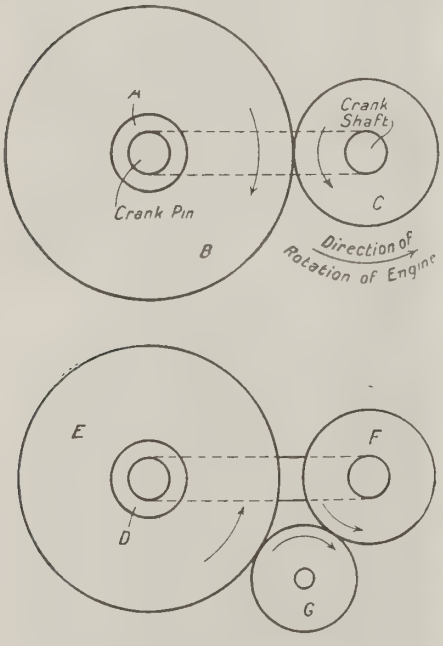
features of the engine. Fig. 10 indicates in diagram form the essential ideas involved. The nine exhaust valves are operated by three cams A, B, C, formed on a sleeve which is extended to provide an internally geared wheel D. The cam member rotates on the sleeve of a gear



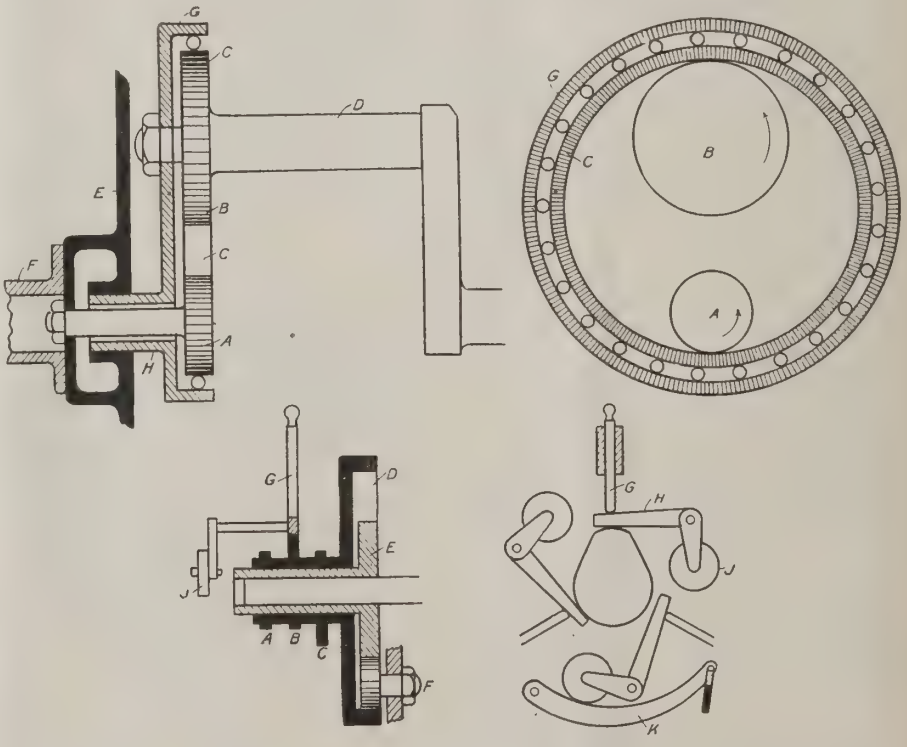


Fig. 8

wheel E fixed on the end of the crank shaft, and meshing with the internal gear wheel D through an idler pinion F pinned on the crank case. The cam member is thus driven at half the engine speed in the same direction as that in which the cylinders rotate.

Associated with this drive of the cam member there is an altitude controlling arrangement. In an ordinary aero engine the power developed falls off as the height of the aeroplane increases, because (1) the percentage of oxygen in a given weight of air decreases as the altitude increases, and because (2) the weight of air drawn into the cylinder decreases, for although the induction volume remains constant the density of the air falls off with the altitude. In Mr. Zeitlin's engine the distance A—Fig. 3—is such that the weight of air drawn into the cylinder at 12,000 ft. altitude, together with that obtained from the crank case with the mixture, is sufficient to permit the engine to develop its full rated power at that altitude. It naturally follows that at lesser altitudes the weight of air drawn in past the exhaust valve during the suction stroke is in excess of actual requirements. To obviate the engine thus running at low altitudes with mixtures that are too weak, Mr. Zeitlin arranges to open the exhaust valve again during a portion of the compression stroke, so that the excess air may be expelled from the cylinder before it has time to mix thoroughly with the explosive vapor. The length of time during which the exhaust valve is held open on the compression stroke can be regulated to suit the altitude. In this way, if the regulation is properly attended to, the engine can be made to give the same power at all altitudes from the ground up to 12,000 feet. The mechanical means whereby the exhaust valve is held open during a variable portion of the compression stroke are indicated in the sketch, Fig. 10. The tappet G, it will be seen, does not bear directly on the cam surface, but has interposed between

PRELIMINARY NAVAL FLIGHT INSTRUCTION

By NICHOLAS S. SCHLOEDER

CONSIDERING the general information available on the art of flying, it is astonishing to find so large a number of students who approach this active work with more or less inaccurate and false preconceived notions of the subject. This is due partly to the many absurd notions of flying entertained by the layman, reflected in newspaper accounts of accidents, where one reads that "he was descending in spiral, when his engine stopped, and he crashed to earth," or that "he was seen to pull his elevator all the way back, yet could not clear the obstruction, crashing, etc." However, as students have already undertaken a theoretical survey of the subject, they know better than this; yet, unless care is taken, beginners often derive many confused ideas.

The reason for this is due to a condition not alone peculiar to aeronautics. On one hand, we have theoretical workers, designers and mathematicians, few of whom are actual fliers. On the other hand we have practical fliers, a majority of whom are deficient in scientific training and habit of thought. Thus, they sometimes fail to convey their acquired knowledge succinctly enough, and their loose generalities often seem to contradict previous study, with resultant confusion.

Another type of preconceived notion is in the psychological aspect of flying. Many students approach actual flying with much misgiving and doubt as to their ability to learn. Dispell it at once. There is no such creature as the "birdman" or the "flying type," about whom once much was heard. While fliers differ in skill and, more often, in daring, any normal person can learn to fly well. Those who can't are very rare indeed. Physical deficiencies and nervousness are not necessarily deterrents. Since the days of Herbert Latham and Chas. K. Hamilton, down to the late Guynemer, even consumptives have become skilled pilots. Hence, students should not take flying too seriously. It is as easy and safe as automobiling, if a few simple rules are not disregarded. Bear in mind, no one ever "gets" into a tailspin, side-slip, etc. Through failure to understand or appreciate some fundamental principle, he might "put" himself into one, but it isn't accidental.

Another psychological aspect is a fear entertained by some students of their instructor. This should be banished at once. Instructors are wont to correct mistakes rather vigorously at times, but this should not be misconstrued. Students have enough to think about flight without worrying about their instructor. They should at all times feel free to ask questions about any difficulties which might occur to them. For this reason I have always considered the relation of instructor and student as the one place where a limited amount of comity is permissible.

The First Flight

Though it has been an accepted practice to confine the initial hop to a joyride, it is best to let the student do as much as is reasonably safe after a few minutes in the air. In this way, students maintain balance and execute turns almost before they realized themselves in flight. They are thus spared of much time and trouble, for I recall in the gradual system under which I was taught, each new function—the rudder, flippers, turns, glide, etc., was a prolific source of concern to me as they occurred, and materially added to the length of instruction. I found a large percentage of students able to maintain themselves reasonably well from the very outset. With a sufficiently clear system of signals, there is no danger of the student "freezing" on the controls.

Signals

For the student to take control, I signal by holding up my right hand with thumb pointed backward to pupil and shake it several times. Now if he climbs too much, I hold up both hands, fingers extended forward, palms down, and by waving fingers signify that pupil should gently push his controls forward to depress the nose of machine. If the nose falls too low, I reverse the position of palms, turning them upward and back, and wave fingers to denote that student must gently draw controls to himself. Upon assuming proper climbing angle, I close hands, indicating that the position should be held. If either wing drops, I point hand on offending side extending outward, palms upward, motioning with fingers to lift wing by raising wheel on that side. (Now, when right wing drops, and right hand raises wheel, the top of wheel moves to left; in stick control the stick is moved over to left; hence, this movement is often called "left aileron;" but this term confuses the student and should be avoided.) When more right rudder is desired; that is, when

Nicholas S. Schloeder, formerly Flight Instruction Officer, U. S. Naval Air Station, Miami, Florida

student should move rudder bar forward with right foot, I hold up right hand and move it forward several times; similarly, left hand for left rudder. I indicate turn by extending arm and sweeping it to right or left, as the case may be. For a glide, I hold up both hands and motion down, fingers extended to indicate proper glide. If the student overcontrols on any of these signals, I repeat the signal and follow by holding up two fingers, denoting "too much." In taking controls from student, I touch my helmet with index finger and shake controls; this is the signal for him to let go of controls *at once,* and put both hands on cowl in plain sight; if I do not find them there upon turning around, the student will be severely reprimanded. In this way I have effectually prevented "freezing" on controls.

Controlling

The average student passes through successive stages in his manner of controlling. The first tendency is to undercontrol; next overcontrol, and finally he controls in the responsive, quick and gentle manner which characterizes the experienced flier. He usually passes from the first stage after a few hours, but in most cases he does not entirely enter the finished stage until many hours of solo flight are passed.

To guide the student to overcome undercontrolling, it might be stated that the order in which the controls may be used with most freedom without endangering stability are: ailerons, rudder and elevators.

The chief reason for the initial period of under control arises from the sensation of novelty which the beginner experiences, which places him under a certain tension. This causes him to grip the controls too tightly and hence his movements are stiff. A student must learn to relax himself without delay—as indeed, many accomplish—and should strive to make his movements light and flexible. He need not be afraid to operate the controls, for he can always correct himself if he has made a mistake.

Soon he begins to overcontrol. At first this is the natural outcome of his initial fault. Later, particularly in his early solo hours, it is due to a tendency to exaggerate the significance of "bumps," etc., which experience in time will overcome. This is easy to understand.

However, it is not so readily appreciated how stiffness in control will lead to overcontrol, so I will give an illustration. Let me assume that a wing is suddenly depressed in flight. A beginner, either because of tension or a still undeveloped "air sense," will be slow to notice this, and makes no move.

Suddenly he recovers himself, and signifies this by imparting a ponderous heave to the wheel. The wing now comes up, but the beginner, with death grip still fastened on the wheel, forgets to neutralize his controls now that their work has been done. So the wing continues upward, depressing the other wing, which soon receives corresponding treatment. Thus he flounders about from side to side, heaving and yanking. An experienced flier, on the other hand, meets the same situation like this. He responds at once, as he feels the wing going down, so that he corrects while, and not after, the air current is tending to depress the wing, so that in most cases he effectively prevents this condition at the start. The air current being past, he at once neutralizes his controls. This difference between crude and experienced fliers may be summed up in a general statement which every student should memorize: A beginner is ponderous, jerky and slow in his use of controls; an expert is responsive, quick and gentle. A beginner's controls appear to move but seldom, but through large distances; they should appear to move more often, but only slightly.

A Straight Course

Longitudinal stability is the first consideration in flight. To ascertain the proper flying angle, it was formerly the practice to define a position on a given machine, such as a part of the rocker arms of engine, which the pilot was to "line up" with the horizon. This made him depend too much on a mechanical device, which, as in clouds, is sometimes wholly unavailable. A student should learn to guide himself by feeling. Apart from sense of balance, the action of engine serves as a gauge. Thus, if the climbing angle is too high, the engine will labor, causing some vibration, while the R. P. M. will fall. Likewise, as the angle increases, the tail surfaces will appear to lose their functions, due to decreased speed and therefore decreased pressure. On the other hand, the engine will race where the climbing angle is too low. Having attained the proper angle, the pilot should endeavor to hold it as steadily as possible, to do which he must be flexible and gentle. In rough weather it is only necessary at times to depress the nose gently and slightly to obtain greater speed; the controls should never be jerked forward and back on encountering a "bump." Learn to "ride" adverse currents, never "fight" them with your elevators.

The relation of engine speed to climbing angle must not be confused with its relation to engine power. In this connection it is important to bear in mind that the proper climbing angle is directly proportional to the power generated by the engine. Thus, when an engine is failing, the angle of climb must be reduced at once. Gravity must be called upon to make up for deficiency in motive power to prevent loss of speed. Induced "nosing her down" is the panacea for nearly all ills of an aeroplane. Hence, a student must always be ready to alight, keep a suitable landing place within gliding distance, and keep ever in mind the direction of the wind.

Wind direction is indicated by streaks in the water running parallel to it, which on calm days are often hard to find or almost entirely absent. The waves furnish a less significant indication, as they are often the result of currents. However, they usually run in parallel lines which are crosswise to the wind. Neither of these signs indicate anything more than the line along which the wind is blowing. The correct alternative may be learned by watching smoke, etc., or better, by observing the general direction on leaving the beach and keeping this in mind.

In the maintenance of lateral stability, the function of ailerons considered alone, presents no special difficulty. The student need only act promptly; less movement will then be necessary.

However, the operation of ailerons in conjunction with rudder is perhaps the most important relation in the art of flying. Some confusing and apparent contradictions are presented.

When ailerons are used to raise a wing, and no change in direction of machine is permitted, the rudder must be increased on the side which is lifted. Thus, if a pilot flies with the right wing dragging, and he raises it with his ailerons, the machine will swerve to the left if he does not increase his right rudder, because of torque. (A dragging wing results in a slight side-slip, and has much the same effect as rudder in overcoming the tendency to the left, as this slip, acting on the vertical tail surfaces, swings the tail to the opposite or high side. Hence some aviators take advantage of this in piloting large H-S boats, where the strain on the right leg is great, by dragging their right wing, thereby relieving the pressure.) In other words, a student who consistently flies with right wing low, does not hold enough right rudder; and similarly, too much right rudder if left wing is down.

Yet the use of opposite rudder in raising a wing, particularly those possessing marked dihedrals, is one of the most elementary and universal in the art of flying. The explanation of this seeming contradiction is this: Where opposite rudder is used, a momentary change of direction occurs. As is evident, the wing on the outer side of the turn will have greater speed and therefore lift, thus bringing it up. To prevent a permanent change of direction the rudder must then be brought back. The temporary character of this rudder function cannot be too strongly impressed on the student.

A further reason for use of opposite rudder results from the slight drag of a lifting aileron, tending to swerve the machine to the side lifted. This again is only temporary, while the aileron is depressed. It is likewise less important than many students have been, incorrectly, advised.

Rudder action for lateral stability, in résumé, really consists of two movements, i. e., first, opposite rudder to increase lift of outer and lower wing and to overcome slight drag, followed by rudder on same side to prevent permanent change of direction; and also, in conformity with the principle that a lifted right wing demands more compensation for torque, and vice versa. Hence, the great importance of flexibility in rudder action, the absence of which being so largely responsible for the yawing of beginners.

Little further need be said about the use of rudder in straight flying. It is well to call to the attention of students that the pressure on the right rudder bar, due to compensation of torque, is sometimes considerable; many are often led to believe that the instructor is executing this pressure, which of course, is not the case. The student must be impressed with the necessity of holding the rudder, for large numbers permit the machine to swerve to the left because of failure to do so. On the other hand, some hold this rudder too steadily, thereby losing the flexibility of rudder action which is so important.

(*To be continued*)

Four types of flying boats and seaplanes used for naval aviation instruction taking off in formation

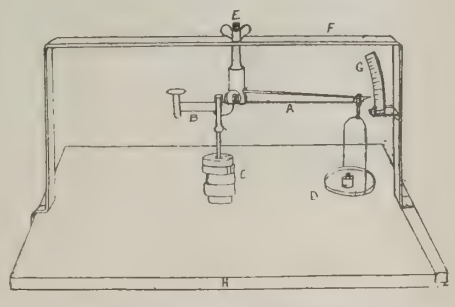
A RELIABLE TAUTOMETER FOR TESTING DOPED SURFACES*

By T. W. H. WARD, Managing Director, Titanine, Ltd.

AS is well known, aeroplane dope has the peculiar property, when applied to fabric, of pulling it taut. Bearing on this property several new words, such as "tauten," tautness," and "tautometer," not appearing, I believe, in any standard dictionary, have had to be coined, but they have the advantage of being readily understandable.

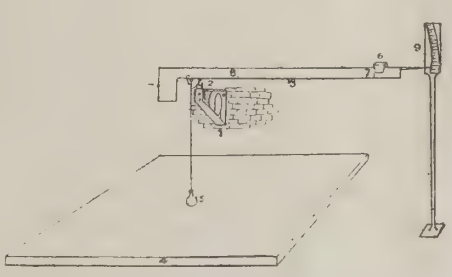
The power of tautening varies with different dopes, hence the necessity for the tautometer, which should measure the degree of tautness brought about by the particular dope or covering employed. Until recently the "tautness" was simply more or less guessed, the method usually adopted being merely to tap the doped fabric and to deduce the tautness from the note produced. The higher the note the greater the "tautening" power of the dope was assumed to be.

The function of a tautometer is to measure the effect of a depressing force, usually exerted by applying a known weight to the center of a known area of doped fabric.



This tautness determination is a measurement of at least two important factors of the dope, i.e., the tension or state of strain given to the doped fabric and the flexibility of the dope film.

The method of tapping has proved to be both inaccurate and misleading. For instance, a hard film is frequently obtained when an acetyl dope is employed and the doped fabric sounds tauter than measurement with a reliable tautometer proves it to be. In reality a high note frequently indicates a hard and brittle film which will have a great tendency to crack on exposure.



There are various types of instruments for example, consists of a heavy round- for measuring "tautness" now in use; one, bottomed framework, having a pivot through the center attached to a spring on the upper side, which, in turn, is connected with a pointer. Except for a knob fixed to the lower end of the pivot only the outer rim of the round bottom of the instrument touches the doped fabric. This instrument is placed on the frame to be measured, and according to the "tautness" of the doped fabric the knob at the end of the pivot is pushed upwards to a greater or less extent, thus compressing the spring and moving the pointer round to a position which may be read off on a circular scale. This instrument has many disadvantages, the chief of which is that only the tautness of the small portion of the doped fabric enclosed by the rim of the instrument is measured. Also, the whole weight of the tautometer on the doped fabric, and that is obviously no small factor in its disfavor. One cannot consider this instrument at all satisfactory, and yet it has been the one most commonly used for the purpose.

Unlike other instruments used for measuring tautness, the tautometer used by my firm is based on the principle of a balance with a 10 to 1 beam (or any other convenient ratio), so that the deflection of the long arm (Fig. A) may be magnified for a slight depression of the other (B).

This beam is suspended on a knife edge in the ordinary way, except that the support is connected with a screw (E) which is used to adjust the beam to any height required. This screw also serves

The tautometer designed by Mr. Ward based on the principle of balance

The usual type of tautometer used for measuring degree of tautness with various qualities of dope

to fix the whole apparatus to a framework (F)—which fits over the frame to be measured in such a way that the specified weight (400 grammes having been adopted in the case of the instrument described) is suspended from the short arm, exactly over the center of the frame. This weight is compensated by a 40-gramme weight (D) in the scale pan, suspended from the long arm (A).

When this tautometer is placed on a frame the reading of the pointer, at the end of the long arm, should be at zero on the curved scale (G) attached to the framework at the right hand side. If this is not the case the necessary adjustment may be effected by turning the screw (E) in the direction required either to raise or lower the beam. When this has been done the 40-gramme weight should be removed from the scale pan. This causes the 400-gramme weight (C), which till now has been just touching the surface, to rest on the doped fabric and the depression due to it may be read off by means of the pointer and scale at the other side. This curved scale may conveniently be divided into divisions representing millimeter (or fraction of an inch) depressions of the 400-gramme weight on the doped fabric.

The 10 to 1 beam has the advantage here of causing quite a perceptible deflection of the pointer for only 1 m.m. depression of the weight, and it must be understood that the smallest deflections are caused by the tautest frames.

The instrument has been in daily use by my firm for two years, with extremely satisfactory results. A simple adaptation on the same principle has also been used for much larger frames (and might with advantage be employed for aeroplane wings), as follows:—

In this case all framework is dispensed with, except for the bracket (1) used for supporting the knife edge (2) of the beam (3). This is fixed to the wall at a convenient height and should stand out half way across the frame (4) (or wing to be measured), so that the weight (5) to be used for determining the tautness may be arranged to touch the center of the frame. The beam, itself, should be counterpoised, as before, so as to give a long arm and a short one, when in equilibrium on the knife edge. Then, as in the previous case, a heavy load is suspended from the short arm to test the tautness of the doped fabric, but, unlike the other tautometer, instead of having the compensating weight in a scale pan, a sliding weight (6) has been adopted, which is placed directly on the beam. When a reading is taken, one slides the weight from the marked position (7) of equilibrium to another position (8) nearer the knife edge, so calculated as to allow the necessary load to rest on the doped fabric. The reading of the pointer on the curved scale (9) may then be read off as before, to show the depresion of the doped fabric caused by the weight of the load.

The great advantage of the principle, described above, is its simplicity, the readings obtained being the direct result of allowing a specific weight to rest on the center of the doped fabric. This is a great improvement compared with other instruments, which, by having their whole weight resting on the surface, both complicate matters and give misleading results.

Book Review

PRACTICAL FLYING, *by Flight Commander W. G. McMinnies, R. N.* This is the first practical work on actual flying and instruction for the flying services, covering the whole field, from elementary groundwork to advanced flying. It is profusely illustrated with diagrams and detailed drawings; also a complete glossary of flying terms and phrases. It is a volume that has been and is extensively used, and highly recommended by instructors of flying, men who have had much experience along this line. Price $1.65, post paid.

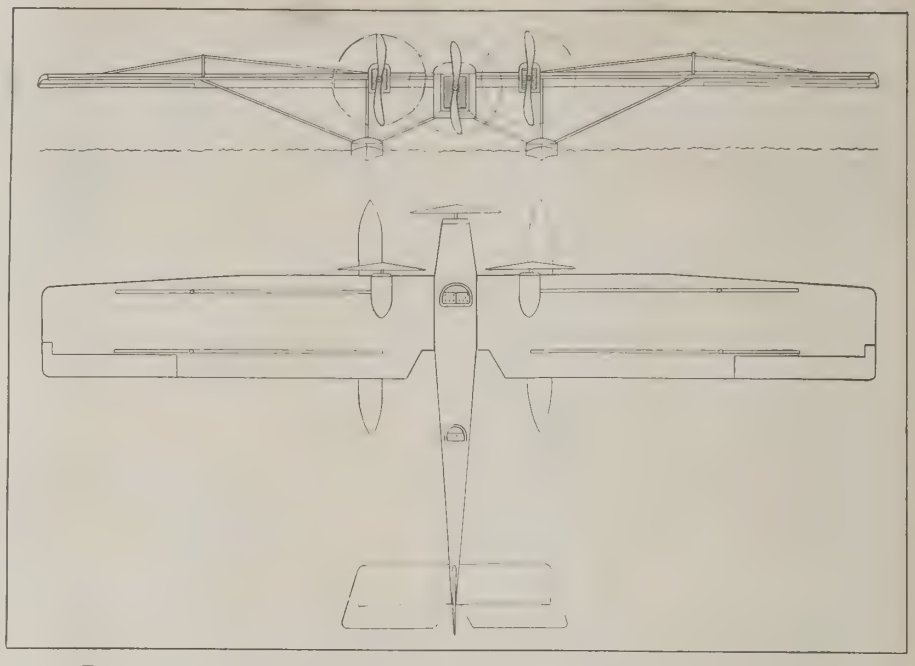
AIR SCREWS, *by M. A. S. Riach.* The author deals with the subject of propellers in a most complete and comprehensive manner. This is a more technical treatise on the subject. The theory in this present volume has been assumed to be absolutely correct and results obtained have been carried to their logical conclusions. It treats of pressure on aerofoils, pitch of an air-screw, the forces acting on an air-screw blade, blade shape and efficiency, blade sections and working formulae, "laying out" the air-screw, stresses in air-screw blades, static thrust, efficiency of an air-screw at different speeds of translation and direct lifting systems, also contains a note on the influence of "aspect ratio" and the effect of the indraught in front of an air-screw. Price $5.75, post paid.

AERIAL PROPELLER, *prepared by Charles B. Hayward.* Design theory of action, thrust, pitch ratio, and construction of the two-blade propeller are the subjects treated of in this instrucive paper. Price 60c, post paid.

TERMES D'AVIATION, GLOSSARY OF AVIATION TERMS ON FRENCH AND ENGLISH. The title alone explains the contents of this valuable publication. Price $1.10, post paid.

These books can be purchased at The Aeronautic Library, Inc., 299 Madison Avenue, New York City.

THE WHITE TRANS-PACIFIC MONOPLANE



AT the Los Angeles factory of the George D. White Company the construction of a triple-motored monoplane is being pushed for the purpose of making a trans-Pacific flight. The White monoplane is of the seaplane type, having twin floats, and is the largest monoplane in the world. Full co-operation has already been secured, the route is mapped and the flight is scheduled to be made within the coming months. A northern route, as shown on the accompanying map, has been chosen as more suitable at this time.

Full co-operation along this route is assured by the Pacific Aero Club, Aerial League of Canada, and by the Governor of Alaska, Hon. Thomas Riggs, Jr., who is preparing arrangements for the stop at Sitka.

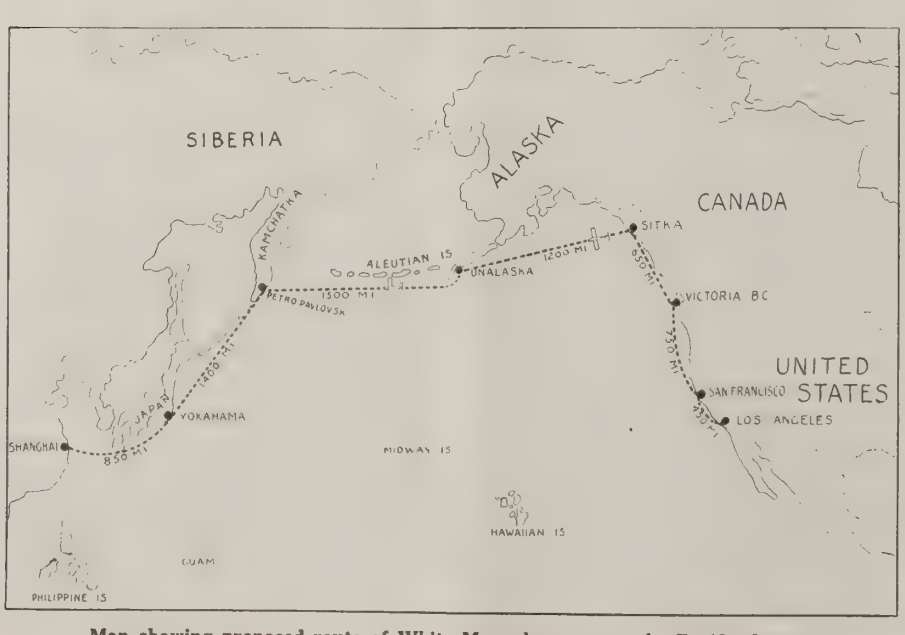
There seems no objection, according to Mr. Riggs, as the average temperature is from 53 to 60 degrees, which is not severe, despite the rather northern point.

From Los Angeles the first jump will be to San Francisco, a distance of 450 miles. From there to Victoria, B. C., a distance of 750 miles. From Victoria to Sitka, Alaska, is a jump of but 650 miles. From Sitka to Unalaska, on the Aleutian Islands, will be an oversea journey of 1,200 miles. This jump completes practically half the journey over the ocean. The next lap is from Unalaska to Petropavlovsk, Kamchatka. This is a 1,500-mile flight and one of the longest to be made, as although some of it is within sight of the islands, the greatest part is across the Pacific Ocean. Technically, the trans-Pacific flight would end here, but the machine will make another hop to Yokahama, Japan, another long flight, but one of comparative ease. The final jump will be to Shanhai, the end of the historic 7,000-mile trip.

A route via Hawaii and the South Pacific Islands has been suggested, but the White Company has decided that this would be impractical, as stops would have to be made either at the many small islands or a non-stop flight of 3,000 miles would need to be made. Although such a flight is not impossible, still one of that length has never been made, and it would be hazardous to the extreme to attempt it over unknown waters.

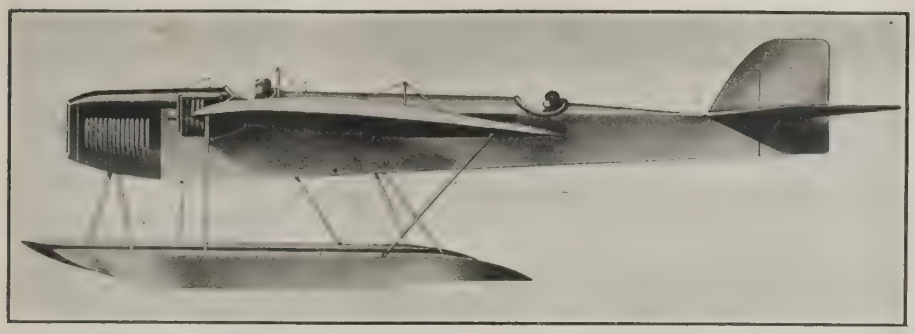
Front and plan views of the 660 H.P. three Hispano motored White Monoplane

The dimensions of the trans-Pacific White monoplane are as follows: Wing spread; 82 feet; length overall, 39 feet; height to top of fuselage, 9 feet; weight empty, 3,700 pounds weight with crew and fuel for the Pacific flight, 7,900 pounds. Total horsepower, 660, generated by three Hispano-Suiza engines. Two 180 H.P. engines are located one on each wing on each side of the body. The third engine, 300 H.P., is installed in the nose of the fuselage as in single-motored aeroplanes. The wings have a peculiar sweepback, raked tips and an angle of incidence of four degrees. The angles are so worked out that the monoplane has practically inherent and automatic laterial and longitudinal stability. All surfaces are balanced, making control simplified and untiring.



Either the two 180s or the one 300-H.P. engine will be used at one time, but all three are not to be used simultaneously. A speed of 110 miles an hour will be given by 300 H.P. By having approximately the same amount of power in reserve as is being used, the possibility of failure is lessened. At the start, the two 180s will be used with the 300-H.P. center engine in reserve. After running a number of hours the central engine will be switched on and the two smaller engines shut off. This method will be followed throughout the entire flight, which allows the engines to rest, and also allows the engine expert to make an inspection and the necessary minor adjustments; new spark plugs can be installed, carburetor adjustments made, ignition troubles overcome, or other minor requirements which, under ordinary conditions, mean motor failure and an interrupted flight.

The White truss system is used in the construction of the wings; no wires are used in the construction whatever, and no cables for the controls or other parts.



The fuselage is constructed as a compact unit, with no wires or turnbuckles. The fuselage is built of Haskelite, a strong veneer built up of Oregon spruce and African mahogany, which is cemented together under hydraulic pressure. This gives enormous strength, is water-tight and gives perfect alignment.

The pontoons, two in number, are spaced 15 feet apart, and extend more than half the entire length of the machine. They are constructed of mahogany and cedar veneer, and are divided into many compartments, sectioned with bulkheads. Either pontoon is capable of supporting the entire machine.

The principal object in the White Company's entry to cross the Pacific Ocean is to blaze the way along a practical route that can be followed later in practical service. In view of the fact that great import trade is springing up with the Far

Map showing proposed route of White Monoplane across the Pacific Ocean

Side view drawing of the White Trans-Pacific Monoplane

East, a quick passage for mail and light express is a necessity, and the route planned is estimated to take three days, compared with three weeks by the fastest boat.

It has been pointed out that should the rules of the Thomas H. Ince prize bar the machine from participation due to the northern route chosen, the flight will be made in any event. Later it is planned to remodel the monoplane, substituting a landing gear for the floats, and attempt to make a non-stop flight from Los Angeles to Chicago.

HELIUM

UP to the present time all military and most other balloons have been filled with hydrogen. This gas, although giving the greatest lift which it is possible to secure, is so highly inflammable as to make the destruction of balloons by fire, not only in war time, but during operations under ordinary conditions, a serious matter. For example, the writer happens to know personally of twenty-six cases in which kite balloons or dirigibles have been completely destroyed by fire, caused by atmospheric or frictional electricity, during the last two years. Many attempts have been made to minimize this fire hazard by fire-proofing balloon fabrics, and by use of hot air or ammonia in place of hydrogen, but so far without success. The use of helium instead of hydrogen affords absolute safety from fire, whether caused by accidental electric sparks or by incendiary or explosive bullets of an enemy in time of war. An adequate supply of helium will, therefore, entirely revolutionize balloon practices, and will do more than any other one thing to assure to the nation possessing it, that control of the air which will in the future be absolutely necessary for any adequate plan of National Defense.

The history of helium is interesting. About 70 years ago, a line was discovered in the spectrum of the sun's atmosphere, which could not be identified as belonging to any element known on the earth. This unknown gas was, therefore, named helium. Many years later, a thimble full of a gas, occurring in very minute quantities in the earth's atmosphere, was isolated by Sir William Ramsay, and proved to be the hitherto unknown element to which the name helium had been given. It was then proved to be not only incombustible but inert in every other chemical way and to have about twice the density of hydrogen. Still later it appeared that this gas is formed whenever radium or any other radio active material disintegrates and for a time active chief source from which helium was obtained in small quantities for scientific research was certain radio active minerals. Still later helium was found to be a constituent of certain natural gases, particularly those occurring in Southern Kansas, parts of Oklahoma and Northern Texas, and processes were developed at the University of Kansas for purifying it so cheaply that it could be sold to scientists, in small quantities, at something like $1700.00 per cubic foot. At that time the total quantity of reasonably pure helium in the world was probably less than 100 cubic feet. In the face of so discouraging an outlook, some one in the British Admiralty had imagination enough to propose seriously, that helium should be produced in sufficient quantities for the British Balloon Service, and experiments were undertaken in Canada for this purpose. A report on this matter was found in a mess of British documents sent to this country soon after we entered the war, by the Gas Warfare Committee of the Bureau of Mines and the matter was brought to the attention of the Signal Corps and the Burtau of Steam Engineering. Since that time about six millions have been either spent or obligated, the entire practicability of the production of helium on a large scale at a cost of ten to fifteen cents per cubic foot has been demonstrated, and production plants to yield 40,000 to 60,000 cubic feet per day are now being constructed or under test.

Three processes, alike in fundamental principles, but differing in important details, are being tried. One of these, the Linde process, has demonstrated its success and is the basis of the production plant now being built. The second, the Claude process, gives promise of a somewhat lower operating cost than the Linde process, but has not yet been entirely perfected. At present, this plant is temporarily shut down until the new Government pipe-line can provide it with an adequate supply of undiluted Petrolia gas, at which time the final test will be made. The third process, invented by Norton and developed by the Bureau of Mines, is the basis of the large experimental unit in Plant No. 3. This unit is still being worked into shape by Norton, the inventor, and it is hoped that satisfactory results will be forthcoming within the next two months. It gives promise of an operating cost lower than either of the others.

The active supervision of the production program for helium, with the exception of Plant No. 3, has been placed in the hands of the Navy Department by mutual agreement between the Army and Navy. All that it is necessary for the Army to do at the present time, is therefore, first, to keep in touch with the work the Navy is doing in behalf of both Departments; second, to prepare itself for the proper utilization of the helium that will be supplied to it under the agreement with the Navy, and third, to assume the responsibility of providing an adequate supply of the necessary raw material, in the future.

It is further suggested that there is much to be done before the Army will be ready to use this new gas in the most effective way. A small repurification plant has already been authorized and plans for it are nearly completed. The question of modifying the designs of the various types of balloons in use, so as to make them appropriate for helium, should be undertaken at once. The chief difficulty is connected with the very large waste of gas involved in the methods of handling balloons at present in use. This waste of gas will have to be very largely reduced by careful experimentation and by changes both in balloons and in the manual of tactics before the use of helium in balloons of the Army types will be justified from the point of view of the whole problem of National Defense.

Finally, it must be remembered that the supply of helium in the United States, although large, is by no means unlimited. At the present time probably a million cubic feet per day is being fed through the natural gas mains of various cities in the Middle West and being dissipated into the atmosphere through thousands of chimneys. Steps should be taken at the earliest possible moment to secure for the Army and Navy the right to process all supplies of natural gas containing usable quantities of helium before this gas is distributed. The details of such a procedure will require careful study and for this purpose an Argon Conservation Committee consisting of a representative of the Navy, a representative of the Army and a representative of the Bureau of Mines was appointed last August by the Aircraft Board and an adequate allotment to cover its expenses recommended. For various reasons effective action by this Committee has seemed impossible until very recently. It is now hoped that the Committee can proceed with its work in the near future.

Book Review

THE AMERICAN AIR SERVICE, *compiled by Arthur Sweetser*, with an introductory chapter written by Newton D. Baker, Secretary of War. This is a story of American military aviation. Every phase of our war program and many facts unknown to the public, such as hitherto unpublished figures, cablegrams and other data are included in this valuable historic volume. Beginning with the early experiments, the author traces briefly the rapid advancement in aeronautics. This is an invaluable book and every aeronautical enthusiast should have it in his or her library for future reference. Price $2.75, post paid.

This book may be purchased at The Aeronautical Library, Inc., 299 Madison Avenue, New York City.

NAVAL and MILITARY AERONAUTICS

4,844 American De Havilands Delivered to Date

Washington, D. C.—The Bureau of Aircraft Production received during the week ended July 15, two De Haviland 4 planes, making a total of 4,844 produced to date.

The table shows deliveries of De Haviland 4 planes (including 204 without engines used in A. E. F. as spares) before and after the armistice:

	Deliveries	Per cent of total
Before armistice.....	3,431	71
After armistice.....	1,413	29
Total	4,844	

265 Seaplanes to Be Sold By Navy

Washington, Aug. 2.—Acting Secretary of the Navy Roosevelt anounces that Secretary Daniels has authorized the sale of 265 seaplanes belonging to the navy. Mr. Roosevelt says that the sale of these machines will give commercial aeroplane transportation companies an opportunity to buy high-speed machines of large carrying capacity ready for immediate delivery. He says that a number of such routes are already in operation or contemplated in the near future, such as from New York to Atlantic City, San Pedro to Santa Catalina, Key West to Havana, Chicago to Milwaukee and other lake cities, and a projected route to the Bermuda Islands.

The sale will include 83 RS-2 pusher biplanes, each with 330 horsepower Liberty motors; also 72 H-6 and F-5 tractor biplanes, each with two 330 horsepower Liberty engines.

The Bureau of Supplies and Accounts, salvage and sale section, will issue complete schedules of the sale, giving the characteristics of all the machines to be sold, their location, appraised value, specifications and terms.

Aircraft Appropriation Withdrawals

Washington, D. C.—The unused balance of the appropriation for the fiscal year ending June 30, 1919, as modified by the Third Deficiency Act for the Bureau of Aircraft Production amounts to $170,743,000 of the $360,647,000 appropriation, the withdrawals amounting to $189,904,000. For the Department of Military Aeronautics the appropriation was $107,469,000, withdrawals $27,328,000, balance $80,141,000, according to a statement issued by the Statistics Branch of the General Staff on July 23.

The withdrawals during June for the Bureau of Aircraft Production were $18,626,000 or 9 per cent of the total; the Department of Military Aeronautics withdrew $1,681,000 during June.

Gale Wrecks Army Bombers

Mineola, N. Y.—Five aeroplanes, including the Martin bomber intended for the one-stop transcontinental flight, the Caproni bomber and a Handley Page bombing plane, were wrecked when a terrific thunderstorm passed over Hazelhurst Field, dismantled buildings and uprooted huge trees. A Caproni triplane, almost completed, was badly damaged by the wind. The damage totals several hundred thousand dollars.

Sales of Surplus Supplies

Washington, D. C.—The Statistics Branch of the General Staff reports the sale of the following supplies: Department of Military Aeronautics, week ending July 18, $801; total to July 18, $3,497,324; estimated value of supplies, Jan. 1, 1919, $85,000,000; estimated cost of material sold, $21,800,000; per cent of material sold, 26.

The figures for the Bureau of Aircraft Production are: Sales for week ending July 18, $296,447; total to July 18, $4,360,207; estimated value of service January 1, 1919, $62,000,000; estimated cost of material sold, $7,600,000; per cent sold, 12.

The unliquidated contracts for the Air Service represent but 9 per cent of unliquidated War Department contracts.

No Reductions in Army Pay

Washington, D. C.—Instructions are being sent to the Commanding General of each depot, the commanding officer of each camp, post or station and each recruiting officer, in effect that newspaper reports that pay of enlisted men will revert after the recent emergency to pre-war scale are incorrect; that the appropriation bill for the fiscal year 1920 provided that provisions of Act approved May 18, 1917, in so far as it increased the pay of enlisted men of the Army, are continued in force and in effect from and after the date of approval of this appropriation act of 1920. It is directed that all concerned give wide publicity to these facts.

Dimensions of Navy Dirigible Hangars Announced

Washington, D. C.—According to information disclosed by Secretary Daniels regarding the naval dirigible hangar to be erected at Lakehurst, N. J., it will be 800 feet long, 265 feet wide, and 174 feet high. These are inside dimensions. The great concourse is 760 feet long, 126 feet wide, and 50 feet high.

The outside dimensions of the hangar are even greater. The space actually occupied will be 920 feet long and 352 feet wide, and the structure will be more than 200 feet. The doors, of which there will be four, two at each end, are 129 feet wide and 174 feet high.

The steel tonnage will exceed 6,000 tons, and the cubic contents of the building will be 50,000,000 feet. It will be covered with colored, corrugated asbestos, which will make it fireproof. A series of windows and skylights on all sides will afford ample light, while there will be numerous staircases and two huge elevators leading to the roof. In the spaces between the great trusses will be placed numerous shops for the use of the aviators.

Three railroad tracks will run the length of the hangar. The building will hold one 10,000,000 cubic feet ship and two smaller ones at the side, or two 5,000,000 cubic feet ships side by side.

Victory Ribbon Bars Buttons and Medals Being Distributed

Washington, D. C.—The War Department announces that the Victory ribbon bar, the Victory button and the Victory Medal are now available for distribution at Army posts, camps and recruiting offices.

The motor truck unit for captive balloons mounts not only the power driven winch, but spare parts, telephone apparatus, scientific instruments, camping paraphernalia, etc.

the President, or of the Secretary of Aeronautics under the direction of the President, shall have supervision of all Air Forces of the line and of the staff divisions of the Air Forces hereinbefore mentioned and shall perform such other duties pertaining to aeronautics not otherwise assigned by law, as may be assigned to him by the Secretary of Aeronautics, and ten brigadier generals, ninety-eight colonels, two hundred and five lieutenant colonels, four hundred and fifty majors, seven hundred and eighty-five captains, nine hundred and ninety first lieutenants, one thousand one hundred and forty second lieutenants, who will be commissioned in the line of the Regular Air Force; and one brigadier general, fourteen colonels, twenty-five lieutenant colonels, forty-five majors, eighty captains, who will be commissioned in the Administrative Division of the Regular Air Force; and one brigadier general, seven colonels, ten lieutenant colonels, fifteen majors, twenty captains, who will be commissioned in the Legal Division of the Regular Air Force; and one brigadier general, fifteen colonels, twenty-five lieutenant colonels, forty majors, eighty captains, one hundred and twenty first lieutenants, two hundred and thirty second lieutenants, who will be commissioned in the Supply Division of the Regular Air Force; and one brigadier general, fourteen colonels, twenty lieutenant colonels, thirty-five majors, seventy captains, one hundred first lieutenants, one hundred and fifty second lieutenants, who will be commissioned in the Engineering Division of the Regular Air Force; and one brigadier general, seven colonels, fifteen lieutenant colonels, twenty majors, sixty-five captains, one hundred and ten first lieutenants, who will be commissioned in the Medical Division of the Regular Air Force: *Provided,* That not to exceed two brigadier generals, eight colonels, twenty lieutenant colonels, and twenty majors of the line of the Regular Air Force may be detailed in the Operations Division: *Provided further,* That officers holding permanent commissions in the Army, Navy, or Marine Corps, now serving, or who have served, in the Army Air Service, the Naval Flying Corps, or the Marine Corps Flying Corps between April 6, 1917, and November 11, 1918, and such temporary officers of the Army, Navy, and Marine Corps, as hold active commissions in the aviation branches thereof at the time of the passage of this Act, shall be eligible for appointment and commission in the Regular Air Force without examination: *Provided further,* That such emergency officers of the Army, Navy, and Marine Corps, who served honorably and at least thirty days on active duty between April 6, 1917, and the passage of this Act, with the Army Air Service, the Naval Flying Corps, or the Marine Corps Flying Corps, shall be eligible for appointment and commission in the Regular Air Force: *Provided further,* That at least 20 per centum of the grades hereinbefore mentioned, below that of major general and above that of second lieutenant, shall not be filled until six months after the passage of this Act, at which time they shall be filled by promotion of the then commissioned officers of the Regular Air Force, under such regulations as may be prescribed by the Secretary of Aeronautics, and, that after one year after the passage of this Act, promotions shall be governed by the rules of seniority. And that the number of second lieutenants hereinbefore authorized is hereby increased in the number of six hundred and ninety until such time as promotions to the grades hereinbefore reserved shall reduce the number of second lieutenants to one thousand five hundred and twenty: *Provided further,* That the pay and allowances, including increased pay for participating frequently and regularly in aerial flights, shall be the same as that now provided by law for commissioned officers of the Army, including retirement: *Provided further,* That increased rank will not be given commissioned officers on account of any ratings authorized for aviators or aeronauts.

Sec. 11. That the grade of pilot shall be, and is hereby, authorized. Pilots shall be known as warrant officers of the Regular Air Force and shall rank with but after second lieutenants: *Provided,* That the pay and allowances of pilots shall be the pay of a second lieutenant and the allowances of a master electrician, and they shall be eligible for retirement after serving the same number of years required by law for enlisted men: *Provided further,* That not to exceed two thousand may be warranted in this grade: *Provided further,* That former officers of the temporary forces of the Army, Navy, and Marine Corps, reserve officers provided for in section 13 of this Act, and enlisted men of the Department of Aeronautics shall be eligible for appointment as warrant officers after passing such practical and theoretical tests in aeronautics as may be prescribed by the Secretary of Aeronautics: *Provided further,* That the appointment of an enlisted man as a warrant officer shall not discharge him from his enlistment.

Sec. 12. That the enlisted strength of the Air Force shall not exceed fifty thousand men and shall consist of master electricians, sergeants (first class), mess sergeants, chauffeurs (first class), sergeants, chauffeurs, corporal, buglers (first class), burglers, privates (first class), and privates, the number of each grade being fixed by the President from time to time: *Provided,* That all enlisted men of the Army, Navy, or Marine Corps on aviation duty at the time of the passage of this Act may be discharged from the Army, Navy, or Marine Corps and reenlisted in the grade of the Regular Air Force carrying the nearest pay to that which they held when discharged: *Provided further,* That the term of enlistment in the Regular Air Force shall be for one or three years: *Provided further,* That the pay and allowances of enlisted men in the Regular Air Force shall be the same as the corresponding grades and ratings of the Regular Army, including the increased pay for participation in aerial flights: *And provided further,* That any enlisted man who may qualify therefor shall be given the rating of aviation mechanician.

Sec. 13. That the Reserve Air Force of the United States shall consist of an Officers' Reserve, available for service as temporary officers of the Regular Air Force, as officers of the line, and of the various staff divisions provided for in this Act under such rules and regulations as the President may prescribe not inconsistent with the provisions of this Act. The President shall be authorized to appoint and commission as reserve officers in the line and the various staff divisions of the Reserve Air Force in all grades up to and including that of major, such citizens as, upon examination prescribed by the President, shall be found physically, mentally, and morally qualified to hold such commissions: *Provided,* That the proportion of officers in any section of the Reserve Air Force shall not exceed the proportion for the same grade in the corresponding section of the Regular Air Force, except that the number commissioned in the lowest authorized grade in any section of the Reserve Air Force shall not be limited. All persons now holding commissions in the Aviation Section Signal Reserve Corps, or in the Aviation Section of the Naval Reserve Force and the Marine Corps Reserve, shall, for a period of three years after the passage of this Act, be eligible for appointment in the Reserve Air Force in the rank nearest that held in the Army, Navy, or Marine Corps Reserve at the time of the passage of this Act without further examination: *Provided,* That such of these as hold commissions as colonel or lieutenant colonel may be commissioned in that rank, but when such persons thereafter shall become separated from the Reserve Air Force for any reason, the vacancy so caused shall not be filled, and such office shall cease and terminate. The commissions of all officers of the Reserve Air Force shall be in force for a period of five years, unless sooner terminated in the discretion of the President.

Sec. 14. That in time of actual or threatened hostilities, the President may order officers of the Reserve Air Force, subject to such physical examination as he may prescribe, to temporary duty with the Regular Air Force. While such reserve officers are on such service they shall exercise command appropriate to their grades and rank and shall be entitled to the pay and allowances of the corresponding grades in the Regular Air Force from the date upon which they shall be required, by the terms of their orders, to obey the same, to the extent provided for from time to time by appropriations for this specific purpose. The Secretary of Aeronautics is authorized to order reserve officers to active duty for instruction for periods not to exceed thirty days in any one calendar year, and while so serving such officers shall receive the pay and allowances of their respective grades in the Regular Air Force: *Provided,* That with the consent of the reserve officers concerned and within the limits of funds available for the purpose, such periods may be extended as the Secretary of Aeronautics may direct.

Sec. 15. That no reserve officer appointed pursuant to this Act shall be entitled to retirement or to retired pay, and shall be eligible for pension only for disability incurred in line of duty in active service or while serving with the Regular Air Force pursuant to the provisions of this Act.

Sec. 16. That the National Guard Air Force shall consist of such members of the organized militia of the several States, Territories, and insular possessions, commissioned and enlisted, who desire to be and are accepted for service, in the Department of Aeronautics, under such regulations as the President may prescribe.

Sec. 17. That the Secretary of Aeronautics shall annually, at the close of each fiscal year, make a report in writing to Congress, giving an account of all moneys received and disbursed by him and his department, and reporting on the work done by the department.

Sec. 18. That all laws prescribing the work and defining

FOREIGN NEWS

Sir Isaacs Describes New Radio Aid to Aerial Navigation

Speaking at a luncheon of the Aldwych Club recently, Godfrey Isaacs, managing director of the British Marconi Company, told of a new plan his company had for enabling aviators to tell where they were. After mentioning the wireless direction finder, Mr. Isaacs said:

"A further development had given them a new transmitter, which would project into the air a wide divergent beam, something like a searchlight without the light, which would extend over any area required, or, if it was desired, a concentrated beam over some small place, and those beams would convey to the men in the sky automatically the name of the place they were passing over.

"Assuming that a man was passing over the town of Guildford; from the moment he traversed the region over which this beam was playing he would receive the signal, 'This is Guildford,' and would continue to receive that signal as long as he was over Guildford and no longer. In the same way, if he was passing over Windsor Forest he would be told, 'This is Windsor Forest,' and when he came to his aerodrome a beam would tell him, 'This is Hendon Aerodrome!' In that way he thought that one of the greatest dangers to pilots in fog and in darkness was disposed of.

"It required very little imagination to see, a little while hence, some thousands or tens of thousands of names being projected into the skies, so that in whatever part of the world an aeroplane might travel, it would be told continuously and automatically where it was. It would be as easy to learn in the skies where they were as in a railway train when they looked out of the window to see the name of a station.

"Similarly these beams could be equipped to lightships or to buoys in fixed and defined positions, so that even when passing over the sea one would know exactly where one was. When that position of things had developed pilots would no longer lose themselves, wherever they might be."

First Westward Flight Across South America

Santiago, Chile.—Lieut. Locatelli, a member of the Italian Aviation Mission now in Argentina, completed on July 30 an aeroplane flight from Buenos Ayres to Valparaiso, his trip marking the first crossing by air of the South American continent from the Atlantic to the Pacific.

Lieut. Locatelli several days previous covered the first stage of the flight, from Buenos Ayres to Mendoza, on the eastern edge of the mountains, where he waited for good weather. He started early July 30 to complete the flight, crossed the Cordillera of the Andes, and after circling over Valparaiso landed at Vina del Mar, near that city. Later he flew to Santiago, landing at the aerodrome of the Chilean Military Aviation School.

The Italian aviator acted as an aerial mail pilot, bringing several sacks of mail matter from the Mendoza post office and a number of private letters. He was greeted on landing in Chile by members of the Italian colony.

Lieut. Locatelli saw service during the war on the Italian front. He took part in one of the raids over Trieste by Gabriele D'Annunzio's squadron.

Trans-Mediterranean Flight in 5 Hours 40 Minutes

Paris—Capt. Morchal, an aviator, who tried to fly from France to Russia during the war, but was obliged to land in the Austrian lines on July 19, flew in a hydroaeroplane from St. Raphael, Department of Var, across the Mediterranean to Bizerta, Tunis. Capt. Morchal covered the distance of about 450 miles in five hours and forty minutes.

Hydroaeroplane to Explore Congo River Valley

Brussels (Correspondence of The Associate Press).—The Belgian Committee on Aeronautics has decided on the creation of a line of hydroaeroplanes for the Congo colony.

Besides mail and passenger transport hydroaeroplanes are to undertake an important cartographic mission covering thousands of miles, with a view to establishing the cartography of the Congo River. King Albert has contributed to the aerial fund of the mission.

Aerial Transport in Hawaii

Honolulu, H. T.—The air service squadron stationed here is now making frequent flights between Hilo on Island Hawaii, outward distance north of Molokai and Maui 230 miles, and return trip south of Maui over the Alalakeiki Channel, the Auau Channel north of Lanai and south of Molokai, distance 15 miles. Instead of going on a small steamer, a journey of two days, a letter was carried for the Governor of the territory by aeroplane in two hours.

The Farman F-50 Biplane

The F-50 biplane, equipped with twin 275-H.P. Lorraine engines, is being converted for carrying eight passengers. The only structural changes are that a cabin is raised above the top longerons of the fuselage with windows surrounding the entire compartment, completely enclosing the six passengers, pilot and mechanician. The upper wing has a span of 22.35 m.; lower wing, 20.40 m. The over-all length of fuselage is 10.92 m., and height over-all is 3.60 m. Chord, 2.35 m.

Weight, empty, 1800 kg.; useful load, 800 kg. Fuel load, 510 kg. Total load of machine complete, 33,110 kg. The F-50 makes a speed of 150 km. an hour.

Caproni Biplane Carries Fifteen Passengers for 220 Miles

According to information from the Caproni Company, a Caproni passenger-carrying biplane made a flight from Milan to Turin and back, with a load of fifteen passengers, in two hours. The distance is 220 miles.

Fiat Flies 158 Miles an Hour with Two Passengers

Flying a Fiat BR biplane, Mr. Brack-Papa established a world's record, on June 27th, by attaining a speed of 255 kilometers an hour (158½ miles) with two passengers aboard. The flight was officially controlled and the speed certified by a Commission of the Aero Club of Italy. This is the highest speed ever attained in any element; the previous record was 143 miles an hour, established by the Frnch pilot Sadi-Lecoint on a two-seater Spad biplane.

Brack-Papa and his two passengers made their official flight over the Mirafiori aerodrome, in the suburbs of Turin.

British Ministry of Munitions Work Summarized in Parliament

London, Eng.—In his speech in the House of Commons on June 24 introducing the Ministry of Munitions Vote, Mr. Kellaway said that at the outbreak of war the British Army had in its possession about 100 aeroplanes. The Ministry became responsible for aeroplane production on September 12, 1917, when the production had increased to 500 aeroplanes per month. At the date of the armistice—a little more than 18 months later—production had been increased to 4,000 per month. At a time when raw material and machinery was very largely engaged on other essential war production this country was able, thanks to the ingenuity of its craftsmen and the farsightedness of its captains of industry, to make so great a step forward in its aircraft production as that, and the improvement in the fighting quality and the safety of the machines was just as great as the increase in the numbers. There was no question amongst informed men that during the latter stages of the war this country held the supremacy over her enemy in the air. That was due not only to the extraordinary fighting spirit and ingenuity of the men who flew and fought the machines, but also to the ingenuity and patriotism of the craftsmen and the employers engaged in that great industry.

Commercial Air Routes Being Established Throughout Italy

(Translated from *Noi & Il Mondo,* Rome).—In Italy, public and private energies seem to turn to the question of aerial postal service and transportation. All official commission has created a code for the air, and has laid out a vast network of aerial routes which start from the Maritime Alps and from the Julian Alps, descend the Mediterranean Coast and the Adriatic to Otranto. One route connects all the cities of the frontier; other routes cross the Apenines and join the coast routes. Along the lines now ready there are more than 80 hangars and as many intermediate landing places.

It is the design to connect the cities of the continent with the islands; and there already exists the Rome-Naples route. Some days ago an enormous biplane carrying 10 passengers, covered the distance between Milan and Rome in 4 hours and 45 minutes, landing comfortably at Centocelle. Arrangements are advancing rapidly for the practical operation of a postal air line including Naples, Palermo, Tunis, Tripoli. But there is still much to do.

The Farman F-50 type B.n. 2, equipped with two 240-275 h.p. Lorraine engines, which is also remodeled for carrying pilot, mechanician, and six passengers with their baggage

Results of Illinois Model Aero Club's Contests

On July 6th the Illinois Model Aero Club held a hand-launched and R. O. G. distance contest at Ashburn Flying Field for the Villard Cup and AERIAL AGE prizes. The judges were Messrs. Walter L. Brock, E. M. Lair, and James S. Stephens. The contestants were Messrs. Joseph J. Lucas, William Schweitzer, Ellis C. Cook, Ward Pease, and Robert Jaros.

All of the models were twin pushers powered with rubber bands. The record of the contests is as follows:

	Hand Launched	R. O. G.
Lucas	(1) ..... 1,464 ft.	(1) ..... 1,248 ft.
	(2) ..... 1,127 ft.	(2) ..... 1,447 ft.
	(3) ..... 1,148 ft.	(3) ..... 504 ft.
	Total. 3,739 ft.	Total. 3,199 ft.
	Average.. 1,246 1/3 ft.	Average.. 1,033 ft.
Schweitzer	(1) ..... 2,778 ft.	(1) ..... 1,101 ft.
	(2) ..... 1,262 ft.	(2) ..... 1,805 ft.
	(3) ..... 1,329 ft.	(3) ..... 1,006 ft.
	Total. 5,369 ft.	Total. 3,912 ft.
	Average.. 1,789 2/3 ft.	Average. 1,304 ft.
Cook	(1) ..... 1,771 ft.	(1) ..... 1,085 ft.
	(2) ..... 1,709 ft.	(2) ..... 755 ft.
	(3) ..... 1,760 ft.	(3) ..... 705 ft.
	Total. 5,240 ft.	Total. 2,545 ft.
	Average.. 1,746 2/3 ft.	Average.. 848 1/3 ft.

Illinois Model Aero Club Meet

By Jos. J. Lucas

The Illinois Model Aero Club held a Gala Day Hydro Meet on July 13th at Lake Calumet. This Hydro Meet was one of the series for the Laird-Weaver Trophy, which is to be awarded to the member making the best showing in all the model meets held for the year. The men who had hydro models were the Messrs. Wricon, Wells, Pond, Jaros, Schweitzer, Lucas, Hittle, and Pease.

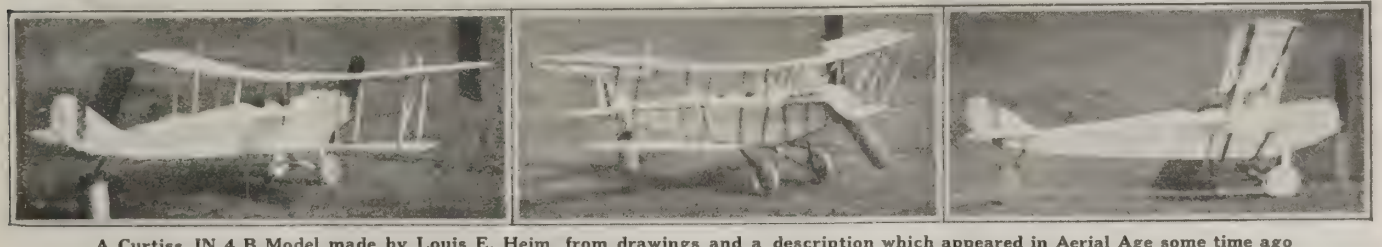
Many long duration hydro flights were made and Mr. William Schweitzer made the best average for his three official flights, winning also the special prize offered by Mr. Partridge for the best duration flight, which was 96 seconds.

The next model aeroplane meet of the Illinois Model Club will be held on August 10th for hand-launched duration and many entries are expected.

Scale Model of Curtiss J N 4 B

Mr. Louis E. Heim, of 421 E. 137th Street, Bronx, N. Y., has built a model of a Curtiss JN 4 B from a description which appeared in AERIAL AGE.

The dimensions of the model are as follows:



Span, upper wing	32¾ in.
Span, lower wing	25½ in.
Chord, both wings	3¾ in.
Overall length	25 in.
Gap	4½ in.
Weight	12 oz.

The model is fitted with sufficient rubber band motive power to enable it to fly 100 feet or over. There is an eight-cylinder dummy motor at the head with a radiator attached.

The landing chassis consists of two struts with brass fittings attached with cotter pins, with an axle ⅛" in diameter running through, on which is attached two 2" aluminum disc wheels.

The wings have a dihedral of ¾". The struts are fastened by means of brass terminal fittings which are attached to the main beams by means of small screw-eyes which are good supports for the wires.

The rudder is fastened by means of wires running through the fuselage to the cockpit, where they are attached to a stick (similar to stick control). The cockpits are fitted with small windshields made of celluloid, which gives a realistic appearance to the machine.

A Curtiss JN 4 B Model made by Louis E. Heim, from drawings and a description which appeared in Aerial Age some time ago

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Military Efficiency

During the war a colonel of the cavalry, assigned to take charge of an aviation field, spent the first day looking through the various departments of his new post.

Surprised at finding so many broken landing gears in the repair rooms, he inquired the reason and was informed that the cause was bad landings on the part of student aviators. Forcibly impressed by this apparent waste and determined to eliminate it, he immediately went to headquarters and issued an order that no more bad landings would be tolerated at that field.

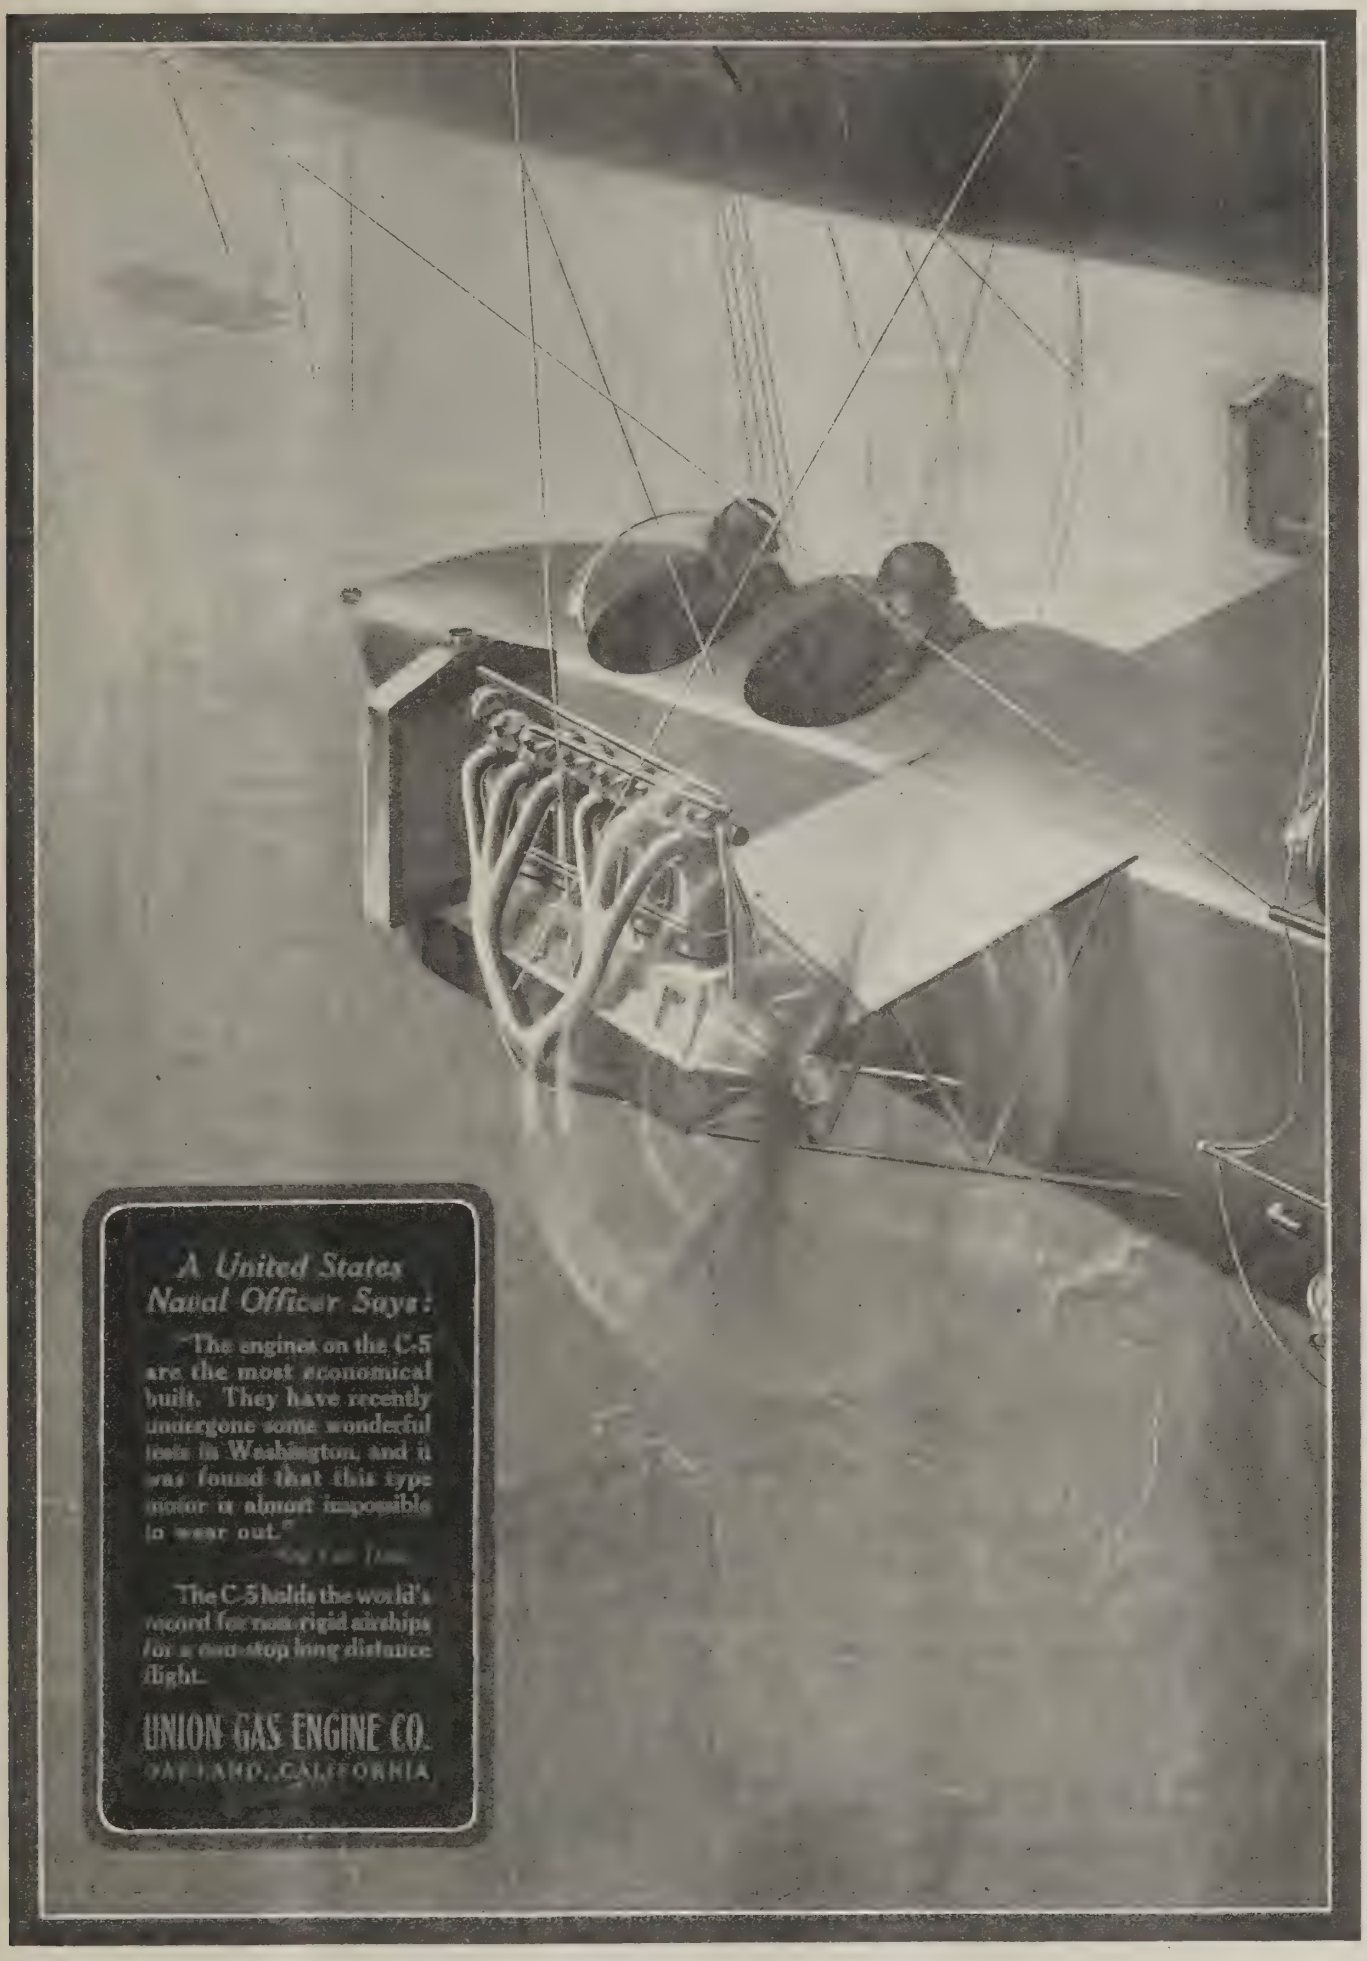
—O. L. D.

The Flying Dutchman: 1919 Version

The soul of a viking wandered down in the wake of a roaring gale
From the frozen bergs in the polar sea that long dead Norsemen sail,
The crystal fleets from the glaciers launched, that lift their ghostly spars
In the flicker and flare of the Northern Lights and the gleam of the cold white stars.
"I want a ship," said the viking's soul, "to speed in the tempest's teeth
When the lash of the wind flails fast and hard the foaming waves beneath.
I would feel the thrill that I felt of yore when I sang to the rhythmic sweeps,
And a new shore rose for my conquering from the haze of unknown deeps."

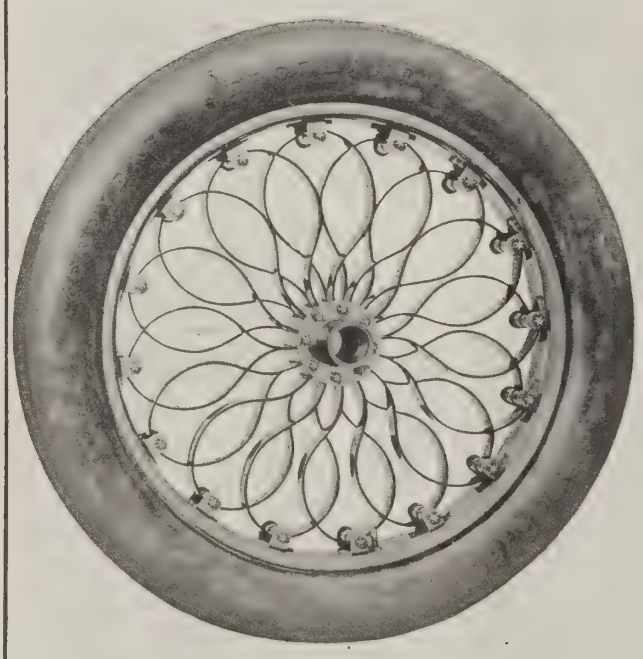
He came to the wild Newfoundland coast and saw in a lonely place
A strange, long ship that tugged and tore like a stallion keen for a race.
"Now here," he cried, "is a noble craft. Ho! this is the ship for me."
And he leaped aboard the long C-5 and sailed away to sea.
Far up in the chill gray fog that hangs and curtains the northern skies,
A rushing form in the Arctic storm, the vagabond airship flies,
And the sea king's hand that steered of yore the war boat out of the fjord
Now guides the great dirigible hence where never its kind has soared.

The Flying Dutchman rests below, but the flying blimp will haunt
The Banks for many a stormy year the fisherman's heart to daunt,
A shape half seen in the rolling clouds through the scudding mist and rain,
Careening out of the inky void and lost in the murk again.
The sailor beating against the wind to the urge of the angry surge
Will see from the gloom of a sudden squall a shadow black emerge
And vanish into the seething night, and will bellow, "Look alive!
There goes the wandering navy blimp, the runaway ship C-5."



Minna Irving, in the New York Times.

A revised map of the Atlantic—Ket in the Oakland "Tribune"



"Skeeter-Time"—Bronstrup in the San Francisco "Chronicle"

A United States
Naval Officer Says:
"The engines on the C-5 are the most economical built. They have recently undergone some wonderful tests in Washington, and it was found that this type motor is almost impossible to wear out."
The C-5 holds the world's record for non-rigid airships for a non-stop long distance flight.

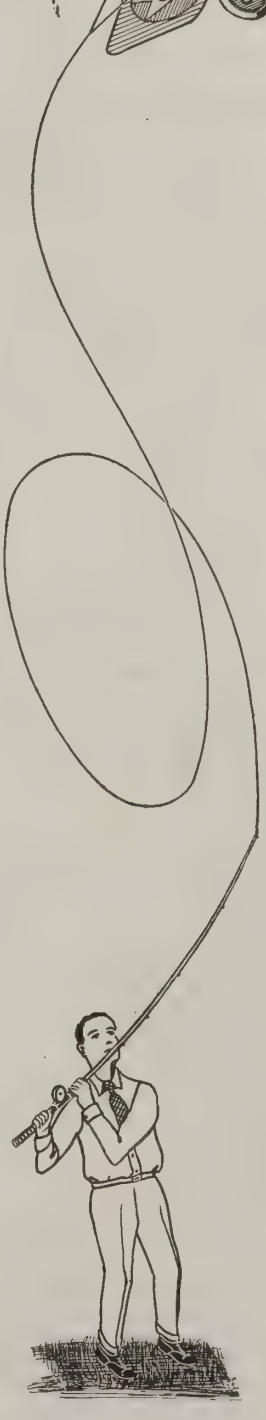
Aviators Knife

a unique and interesting novelty

Can be used as a paper knife, letter opener, or fruit knife. It is made of aluminum beautifully finished. A very handsome desk ornament.



Price 50 cents lettered: 40 cents plain. Special Price by the Gross.

Just what the young boy wants

A model plane, carefully designed and constructed that acts like a regular machine. Its propeller makes a noise like a miniature De Havilland. It has a span of 18 inches, overall length of 21 inches, is equipped with carefully carved propeller, rubber tired wheels, and can be dissembled and assembled very quickly.

Price $2.00.

AEROPLANE INSURANCE

Merchants Fire Assurance Corporation of New York

This company issues policies covering aircraft against the following risks:

1—FIRE AND TRANSPORTATION
2—COLLISION (Damage sustained to the plane itself)
3—PROPERTY DAMAGE (Damage to the property of others)

Additional coverage may be had against loss by wind storm, cyclone or tornado.

We will be glad to discuss problems concerning aeronautic insurance.

(*Continued from page* 1014)

it and the cam the end of a lever H fixed to a short shaft, which, at its other end, carries an arm provided with a roller J. All the nine rollers are arranged in one plane, and pass in turn over a curved cam surface K pivoted to a fixed point at one end, and at the other connected to an indicator handle under the pilot's control. At the ground level the cam K is set fully in so that, as each roller passes over it, the associated tappet is lifted off the cam A, B or C, and the exhaust valve is accordingly held open during a portion of the compression stroke. For starting purposes the cam K is set fully in and acts to the same end as the decompression gear provided on certain other aero engines. As the altitude increases the pilot progressively withdraws the cam out of action, so as to retain in the cylinder more and more of the air drawn into it during the suction stroke, until the normal height for which the engine is designed is reached, at which height the cam K is fully out of action, and the exhaust valve remains closed throughout the entire compression stroke. The actual compression ratio varies from 4.5 to 1 at or near the ground level up to 7 to 1 at high altitudes, although the compression volume remains constant throughout.

It is claimed that the introduction into the cylinder, during the first part of the suction stroke, of a large volume of air in advance of the inlet of the combustible mixture from the crank case, entirely eliminates all possibility of a back fire occurring through the retention in the cylinder of some part of the hot products from the previous working stroke. It is further claimed that the absence of inlet valves conduces to a like result, while being an advantageous mechanical feature for other reasons. Other features of the engine to which special attention is called are the very complete scavenging effected by the extended movement of the piston during the exhaust stroke, the central situation of the exhaust, the fact that all the connecting-rods are of the same size and shape, and the similarity of the functioning of all the cylinders.

Special Orders Nos. 170 to 175 Inclusive

Lieut. Col. John A. Paegelow will proceed to Washington, D. C., on temporary duty; thence to Army Balloon School, Lee Hall, Va., and report by letter to the Director of Air Service, Washington, D. C., for duty.

Lieut. Col. Ralph Royce will report to Fort Sam Houston, Tex., to the commanding general, Southern Department.

First. Lieut. Jesse A. Praether, Air Service, will report to the chairman of the Commission on Training Camp Activities, this city, for duty.

Maj. Archie W. Barry will proceed to San Antonio, Tex., and report in person to the commanding officer, Brooks Field, for duty.

First Lieut. Leo. F. Post will proceed to Mather Field, Sacramento, Cal.

Second Lieut. John W. Rankin will proceed to the aviation repair depot, Montgomery, Ala.

Capt. Phil A. Henderson will proceed to Fort Sam Houston, Tex., and report in person to the Department Air Service Officer, Southern Department, for duty.

Second Lieut. William Slade will proceed to Fort Sheridan, Ill., and report in person to the commanding officer, United States Army General Hospital No. 28, for further observation and treatment.

First Lieut. Bruce Struthers will proceed to Fort Bliss, El Paso, Tex., and report in person to commanding officer for assignment to duty with the 96th Aero Squadron.

Second Lieut. Yancey C. McDaniel will proceed to Petrolia, Tex., and report in person to the department air service officer, Southern Department, for duty as officer in charge of gas plant, No. 3.

Lieut. Col. Barton K. Yount will proceed to March Field, Riverside, Cal., and report by letter to the Director of Air Service, Washington, D. C., for duty.

First Lieut. Edmund T. Allen will report in person to the commanding officer, Langley Field, Hampton, Va., for duty.

Col. Halsey Dunwoody will proceed to Washington, D. C., and report to the Assistant Secretary of War for assignment to duty in his office.

Second Lieut. John Lawson Leonard is transferred to United States Army General Hospital No. 28, Fort Sheridan, Ill., and will report to the commanding officer, that place, for further observation and treatment.

First Lieut. John D. Cox will report in person to the commanding officer Letterman General Hospital, San Francisco, Calif.

Lieut. Col. Benjamin F. Castle is detailed as assistant to the military attaché, Paris, France, and will report to the military attaché, American Embassy, Paris, for assignment to duty.

The following-named second lieutenants will proceed to Barron Field, Everman, Tex.: Henry E. Wooldridge, Paul H. Prentiss, William B. Atwell.

Col. Olan C. Aleshire will proceed to Fort Sam Houston, San Antonio, Tex., to the commanding general Southern Department for duty as assistant department Air Service officer.

First Lieut. Robert Furrer Linkenhoker will proceed to Whipple Barracks, Ariz., and report in person to the commanding officer United States Army General Hospital No. 20 for duty.

Maj. Frederic C. Phelps will proceed to Taliaferro Field, Hicks, Tex., and report by letter to the Director of Air Service.

First Lieut. William H. Preece will report in person to the commanding general Camp Lee, Va., for discharge.

VOL. IX NEW YORK, AUGUST 18, 1919 NO. 23

CAPT. CHARLES J. GLIDDEN OFFERS GLIDDEN EFFICIENCY TROPHY

TO bring about the use of aeroplanes for touring and general use, Captain Charles J. Glidden, the noted sportsman, who contributed extensively to the development of automobiling by organizing the Glidden Automobile Tours, has offered a trophy for aeroplane touring through the Aerial League of America, of which Rear Admiral Peary is president.

The trophy is to be known as the Glidden Aeroplane Efficiency Trophy, and is to be competed for under the auspices of the Aerial League of America, under rules similar to the rules which governed the automobile tours for the famous Glidden Automobile Trophy.

In making the offer of the Glidden Aeroplane Efficiency Trophy, Captain Glidden wrote to Rear Admiral Peary, the president of the Aerial League of America, expressing his belief of the great future of aviation, as follows:

"My dear Admiral Peary:

"I am happy to learn that so many members of the Aerial League of America are purchasing aeroplanes for sport, pleasure and transportation.

"It is indeed most gratifying to find that manufacturers are overwhelmed with orders and cannot produce fast enough to meet the demand.

"The experience of that aeroplane manufacturer who doubled his production three months ago, but is still behind in his deliveries because the orders for aeroplanes have quadrupled in volume, only gives an idea of what is to come.

"The five hundred people who have bought aeroplanes during the past four months and the hundreds who are placing orders and clamor for deliveries are only the vanguard of an army of thousands of people who will own aeroplanes in the near future.

"More people would own aeroplanes now if they could get deliveries, and more if there were more landing fields where they can start from and land their planes.

"We need more landing fields through the country, and the Aerial League of America deserves great credit for its work in getting cities to establish fields.

"Had we flying fields at every twenty or fifty miles from New York to San Francisco, transcontinental flights would be daily occurrences, because we have the aeroplanes that can make the flights, the people interested in making the flights, and aerial travel has many advantages and attractions.

"I believe that our engineers and manufacturers are capable of producing even better aeroplanes than were produced for the war, and that these planes will be produced as soon as something is done to bring out the qualities required in aeroplanes, to be used for pleasure, transportation, and commercial purposes.

"To assist in this constructive work, and believing that aerial tours is the best and quickest way of bringing about the use of aeroplanes for general purposes, and improving the construction of aeroplanes, and cause the establishing of flying fields throughout the country, I will gladly contribute a trophy to be competed for under rules similar to the rules of the Glidden Automobile Trophy."

Captain Glidden's generous offer has been accepted by the Executive Committee of the Aerial League of America, and the rules for the Glidden Aeroplane Efficiency Trophy are being drawn by a committee of which Major Reed G. Landis, second ranking American Ace, is chairman.

Captain Charles J. Glidden, who is the publicity officer, Air Service, United States Army, is about to leave the Army, having requested discharge. He was a pioneer in the automobile field, and as the donor of the Glidden Trophy for automobiling and as a world-touring automobilist he contributed much to the development of the automobile. He was also a pioneer in aeronautics, becoming interested in ballooning twenty years ago. He holds the American, French and British balloon pilot certificates, and was one of the founders of the Aero Club of America, in 1905. He entered service at the United States Army Balloon School as an officer, June 12, 1917, at Omaha, Neb., then became department aeronautical officer, Northeastern Department, Boston, Mass., and organized the aeronautical department and secured in two months 2,000 applications for balloon pilots and aviators, and when transferred applications were coming in at the rate of forty per day. His transfer was to Omaha, Neb., where he became the president of the Aviation Examining Board. He had twelve states and secured in four months 4,000 applications for balloon pilots and aviators, personally passing on mental qualifications of over 2,000 men, to join the service. As personnel adjutant, U. S. Army Balloon School, Fort Omaha, Neb., he had the assigning of men to proper positions and for overseas, and passed on 4,000 men.

Later he was representative of the General Staff at Atlanta, Ga., for seven states to secure staff officers, and at the time the armistice was signed applications were coming in at the rate of fifty a day. He had secured 250 in ten days. He was transferred to the Souther Field, Ga., for administrative work, and at one time held fifteen positions, including personnel adjutant and publicity officer.

In April, 1919, he was placed in charge of the recruiting campaign for the Air Service, and in a short time secured the names of 17,000 persons interested in aviation who were assisting in obtaining recruits.

He was transferred to Washington and started the Air Service publicity, and issued stencils daily showing activities of the Air Service, as news all over the United States, showing many exceedingly interesting events unknown, such as forest fire patrol, cross-country flying, etc., etc., etc. From May 14 to August 8, 1919, he issued 115 stencils containing nearly 2,000 items of Air Service activities.

In conference with Chief of U. S. Weather Bureau and forecasters he arranged for the adoption by them of a weather forecast for navigators of the air, which is sent to all Air Service stations at 9.30 A.M. and 9.30 P.M. daily, governing their flights as far as weather is concerned, thereby saving loss of life and property and considered one of the most valuable features of the Air Service.

REPORT OF THE AMERICAN AVIATION MISSION ON EUROPEAN TOUR

THE War Department authorizes publication of the following statement by the Secretary of War and of the appended report of the American Aviation Mission of which the Assistant Secretary of War, Benedict Crowell, was chairman:

"In making public the report submitted to me by Mr. Crowell and his associates on the American Aviation Mission, I desire to emphasize the thoroughness and value of the studies made in England, France and Italy with regard to the importance of aircraft and the essential dependence of the art for its development upon a sympathetic attitude in the Government. Those best informed throughout the world are in accord in believing that this new agency of transportation has possibilities upon which it is now quite impossible to set limits. They are further agreed that we face a period, more or less brief, in which the prospect of commercial return is not sufficiently sure to justify private enterprise in developing the aeroplane industry into a self-sustaining position.

"The importance of aircraft as a military arm is obviously so great that we must leave nothing undone both to develop the art in its scientific and practical aspects and to provide facilities for rapid quantity production in the event of emergency.

"From these considerations it is clear that the ingenuity and ability of American engineers and inventors must be coordinated and our national effort freed from wastefulness and duplication.

"The Mission has in my judgment gone too far in suggesting a single centralized air service. Army and Navy aviators are specialists in the art, both the aeroplanes and the pilots needed, are of a different type from those needed in civil undertakings. The pilots particularly need to be trained upon a different theory. Military pilots are trained to fight singly or in formation, and to operate in coordination with other branches of the military service, so that their training must be military. Their own efficiency and that of the other branches of the service depends upon the most intense and constant associated training, and a separation of the Air Service from the Army or the Navy would require coordination of their activities in time of war, whereas effectiveness in military operation rests upon the concentration and singleness of authority, command, and purpose.

"The point emphasized by the Mission is the importance of maintaining adequate production facilities in this country. This it is believed can be brought about best by the establishment of a government agency which will lay down the necessary rules, national and international, for aircraft operation, prevent discouraging lack of uniformity in state regulation, and generally stimulate private and public enterprise in perfecting and using commercially this mode of transportation, and by centralizing the placing of orders on government account so as to have the incidental effect of making them contribute to the maintenance of aircraft production as an industry. It is not proposed, as I understand it, that great appropriations of public funds should be made for the establishment of uneconomic commercial air service routes, but obviously an extension of our air mail service could be made, and it could be further extended as the perfection of machines advances and their reliability of service is more and more established. Such encouragement as the government may find it wise to give can be accomplished without sacrificing the science of military aeronautics. The Joint Board of the Army and Navy is already eliminating duplication and producing cooperation in developing the air service of those departments, and should Congress decide to extend its aid to the commercial development of aircraft, complete cooperation will be easy in all matters of invention, design, and production where the different aspects of the problem meet on a common ground.

"(Signed) NEWTON D. BAKER,
"Secretary of War."

The full report is as follows:

To the Secretary of War.

In accordance with your instructions, the American Aviation Mission visited France, Italy and England. It was able to confer with various ministers of these Governments, ranking Army and Navy commanders, and the foremost aircraft manufacturers.

A thorough study and investigation was made by your Mission of all forms of organization, production and development. As a result of these studies, your Mission desires to emphasize the universal opinion of its members that immediate action is necessary to safeguard the air interests of the United States, to preserve for the Government some benefit of the great aviation expenditures made during the period of the war, and to prevent a vitally necessary industry from entirely disappearing. Ninety per cent of the industry created during the war has been liquidated. Unless some definite policy is adopted by the Government, it is inevitable that the remaining 10 per cent will also disappear.

In placing this matter before you the subject falls into three important heads:

(1) General organization.
(2) Development, commercial.
(3) Development, technical.

The findings of the American Aviation Mission and its recommendations are submitted after a careful review of the situation in the allied countries mentioned, but always keeping in mind the situation in the United States. Under the above sub-heads the results of those investigations are presented to you, which, in the opinion of the Mission, demand the most earnest and immediate consideration along the broadest lines, with a view to establishing some fixed policy which will save the aircraft situation in the United States and give the United States an equal place with the great powers of Europe in this great new commercial development.

The American Aviation Mission therefore recommends: The concentration of the air activities of the United States, military, naval and civilian, within the direction of a single Government agency created for the purpose, co-equal in importance with the departments of War, Navy and of Commerce, to be called in this report, for purposes of identification, the National Air Service.

In making the above recommendations, the following views and data of the Mission are presented:

Visits were made by the Mission to England, France, Italy, and conferences have been held with those largely responsible for the successful prosecution of the war, and especially with those men most experienced in the aerial development within those countries. Among others interviews have been had with:

France:

Marechal Foch, Commander-in-Chief des Armees Alliees.
Mr. Andre Tardieu, Ministre de Affaires Franco Americaines.
General M. Duval, Chef de Service de l'Aeronautique.
Mr. Jacques Dumesnil, Depute, formerly Sous-Secretaire de l'Aeronautique.
Mr. Loucheur, President du Conseil de Guerro, now Minister of Reconstruction.
Mr. Daniel Vincent, Depute, ex-Under Secretaire for Aviation.
Mr. Gaston Menior, Depute, Chief du Comite Aeronautique au Senat.
Major d'Aiguillon, of the Commission Interministerielle de l'Aviation Civile.

England:

Honorable Winston Churchill, M.P., Secretary of State for War and Air.
Field Marshal Sir Douglas Haig, Commander-in-Chief of the British Army.
Admiral Sir David Beatty, R.N., Admiral of the Fleet.
Major General Right Hon. J. E. B. Seely, Under Secretary of State for Air.
Major General Hugh M. Trenchard, Chief of Air Staff, Royal Air Force.
Major General E. L. Ellington, Director General, Supply and Research, Royal Air Force.
Major General Sir Frederick H. Sykes, Controller General Civil Aviation, Royal Air Force.
Sir W. A. Robinson, Secretary, Air Ministry.
Major General Sir W. S. Brancker, Royal Air Force.

Italy:

Signor G. Grassi, Chief of the Italian Aviation Mission in Paris.
Colonel Guidoni, Italian Foreign Aeronautical Mission.
Admiral Orsini, Chief of Italian Naval Aviation.
Colonel Crocco, Chief of the Technical Bureau.
Signor Conti, Secretary of State for Aviation.

In all countries visited, and in the minds of all persons met

THE NEWS OF THE WEEK

75-Minute Flight Between Washington and New York

Washington, D. C.—The air speed record between Washington and New York was broken on August 8 by a De Haviland plane, piloted by Lieut. Col. H. B. Claggett, commander of the Dallas-Boston fliers, who covered the distance of 210 miles from the Capitol at Washington to the Statue of Liberty in 75 minutes. This was an average speed rate of 168 miles an hour. Sergeant Ralph Kratz was a passenger in the plane. The elevation during flight average 4,000 feet.

NC-4's Trip Postponed

Portland, Me.—The exhibition trip along the coast from Portland to Galveston, Tex., of the NC-4, the first plane to make the flight across the Atlantic, has been postponed one month. The plane is now expected to arrive here on October 1.

Aero Club of America Honors Admiral Fiske, Inventor of Torpedo Plane

The Board of Governors of the Aero Club of America announced on August 9 that they had awarded the gold medal of the club to Rear Admiral Bradley A. Fiske, U. S. N., retired, for his invention of the torpedo plane, patented on July 16, 1912, which was used effectively during the war. Announcement was also made of the receipt of the following letter from Rear Admiral Fiske:

"I hasten to express my gratitude to the Aero Club of America for the award of its gold medal and to thank you for your kind letter of presentation.

"To be awarded a gold medal is an honor that any one should appreciate profoundly. To be awarded the gold medal of the Aero Club of America is an honor that is exceptional, because the standing of the Aero Club is exceptional, but though the standing of the Aero Club is very high, the effective work which it carried on throughout the war is not fully appreciated by the nation for the reason that its work was unofficial, and therefore not recognized officially.

"Like many another unrecognized agency, however, its influence was potent and profound. Acting as the advance scout of aeronautic progress, the Aero Club continually gave information to the country of the possibilities of naval and military aeronautics, insisted that those possibilities be utilized, and demanded that Congress appropriate such sums of money as would enable the Government Departments to utilize those possibilities completely and in time.

"Enormous appropriations were then made, but as Congress delayed making them until after we had actually entered the war, the appropriations came too late to permit American aeronautics to do as much effective work as it otherwise could in winning it.

"Your letter gives me more credit than I deserve for furthering the cause of naval and military aeronautics. What little I was able to accomplish should be credited to the Aero Club of America and to the press of the United States, which supported the club's efforts with such keen patriotism and intelligence."

Eddie Stinson's youngest passenger still in smiles at end of 75 mile cross country flight

Committee Going on Month Trip in Aircraft Inquiry

Announcement was made August 10 that the Subcommittee on Aviation of the House Committee on War Expenditures will begin at once a month's inquiry of charges reflecting on John D. Ryan, formerly head of the Aircraft Production Board. Representative Frear, Republican, of Wisconsin, chairman of the subcommittee, issued a statement of the programme, which is to include an inquiry into the sale of surplus linen, contracts for the production of castor beans for oil for Liberty motors, and various other aviation matters.

A portion of Mr. Frear's statement is devoted to criticism of Homer S. Cummings, chairman of the Democratic National Committee, because Democratic publicity recently referred to the proposed trip as a junket. Mr. Frear said this attack justified a statement as to the purposes of the inquiry to be made by him and his colleagues on the subcommittee, who are Representatives Magee, Republican, of New York, and Lea, Democrat, of California.

"Protests from responsible persons on the Pacific coast have been placed before our committee against a proposed sale of railway properties, mills, timber and the like on September 2, which have cost the Government presumably $20,000,000 and more, all of which are involved in the charges. A letter from Senator Jones, of Washington, to President Wilson strongly urging an 'honest to God' investigation was submitted to the committee.

"A remarkable situation developed when we discovered that contracts, vouchers and data covering nearly $50,000,000 of spruce production expenditures were kept at Portland, Ore., and none filed here. The committee is called upon to find out what was done with money spent for spruce production and for logging roads costing more than $100,000 a mile, useful for the Milwaukee and St. Paul Railroad alone."

Lands in 5,000-Foot Canyon in Yosemite Park

Mather Field, Sacramento, Cal.—Lieut. Earl E. Neubig, from this field, completed one of the most difficult flights ever undertaken, from Sacramento, Cal., into Yosemite National Park, the floor of which is 4,000 feet high. In order to make a landing in the park it was necessary for Lieut. Neubig to gain an altitude of 11,000 feet and spiral down between the walls of the canyon, which are 5,000 feet high and one-quarter of a mile wide. He landed on the field, which was very difficult to reach owing to the high trees and wires surrounding it, and his plane stopped rolling just about 10 feet in front of a multitude of park visitors who were there to greet him.

The trip was made in a Curtiss H biplane powered by a Hispano-Suiza engine. The time between Sacramento to San Francisco, 90 miles in 90 minutes; San Francisco to Yosemite, 180 miles in 100 minutes; Yosemite to Sacramento, 90 miles in 90 minutes.

One of the new biplanes used by the New York Police Department, piloted by Captain Bruce Eytinge of the Aerial Police Reserve

45,000 Miles in Forest Fire Patrol

During the six weeks ending August 2, 56 fires have been discovered in the California forests by the aerial forest fire patrol, reported promptly, and quickly extinguished, causing only nominal damage.

The corps of aviators from the three flying stations, Mather Field, Sacramento; March Field, Alessandro, and Rockwell Field, San Diego. have made 373 flights over the forest, a distance of 45,376 miles, in 38,545 minutes. To this can be added the wonderful work of the U. S. Army Balloon School at Arcadia, who have maintained in the air night and day an observation balloon similar to that used on the western front, from which observation has been made personally by the commanding officer of the post and other high officials, including the entire staff, that the service may be maintained at a high point of efficiency. Many fires discovered have been quickly extinguished and no serious damage reported.

Eddie Stinson Carries Young and Old

York, Pa.—"Eddie" Stinson, the famous exhibition flier, has carried the youngest and oldest passengers who have been up in an aeroplane in America, the youngest being Miss Mitzi May Kuntz, aged eight months, and the oldest a woman of eighty-seven. Mr. William J. Kuntz arranged with Mr. Stinson for a cross-country flight, and it was decided to take his baby daughter with him. Starting from York, they flew due north over the Susquehanna River to Goldsboro; then southeast to Cly; then southwest back to York, a total distance of seventy-five miles. The young passenger was smiling and happy after her aerial joy ride.

Pacific Fleet Photographed 150 Miles At Sea

San Diego, Cal.—Taking with him two newspaper photographers, Captain Lowell H. Smith, who holds the record for flight between San Francisco and San Diego, flew 150 miles out to sea in order to obtain photographs of the new Pacific Fleet. On the following day the photographs were delivered to San Francisco by aeroplane.

Venice, California, Opens Aviation Field

Venice, Cal.—An aviation landing field was opened here on August 5. A group of Air Service officers and men from Ross Field participated in the ceremonies. Three ascensions of a 37,500 cubic foot Cacquot captive balloon, each with a parachute jump, were made. The gas from the Cacquot was then deflated into a spherical balloon and three flights were made, one a night flight of two hours over a distance of twenty miles, and two on the morning following.

Curtiss Oriole Makes First Flight Over Pike's Peak

Colorado Springs, Colo.—Lieut. Alex Lendrum of Colorado Springs, in a Curtiss Oriole biplane, circled the summit of Pike's Peak on August 3, reaching an altitude of 14,200 feet. He was accompanied by Ira J. Humphries of Denver and L. L. Law Sipple, a photographer, who filmed scenes of the summit and of the Pikes Peak region. The flight was the first ever made to the crest of the mountain.

Reno to Sacramento in 65 Minutes

Pilot Lieut. W. C. Goldsborough, with passenger, Lieut. J. Parker Vanzandam, in a DeHaviland, on August 2 flew from Mather Field, Sacramento, Cal., to Reno, Nev., 130 miles, in 85 minutes. Maximum altitude was attained over Lake Tahoe of 13,000 feet, and forced landing made at Minden, Nev., in 65 minutes flying time to Minden from Sacramento, against 13 hours by train.

National Geographic Society Predicts Around-the-World Flight

Washington, D. C.—"Now that the Atlantic has been crossed and there are plans afoot to fly over the Pacific, the day may not be far distant when some aerial Magellan will make an aeroplane tour around the world," says a bulletin of the National Geographic Society.

"There are still many corners of the world where aeroplane, automobile and even the horse would be curiosities. And if a man set out to tour the globe and 'do as the Romans do' in respect to adopting native conveyances he would have to:

"Resort to a donkey in Spanish America and in the Holy Land,

"Climb aboard a camel to traverse African deserts,

"Cross some rivers of India on the inflated skins of bullocks, and others by a bridge of one rawhide rope,

"Submit to the sea-going motion of an elephant when he continued his journey on land,

"Get into a man-borne palanquin at Calcutta,

"Jolt over Far Eastern roads in a non-shock absorbing cart drawn by oxen,

"And in China be prepared to climb into a jinrikisha, a sedan chair or a wheelbarrow."

The bulletin continues with a series of picturesque illustrations contrasting aerial transport with systems still in vogue.

Forest Patrol for Oregon Being Organized

Salem, Ore.—Major A. Smith, officer-in-charge of the new aerial forest patrol squadron, which will operate in this vicinity in the near future, arrived here on August 8 from Medford, piloting a Curtiss H biplane. The distance of 210 miles was covered in 160 minutes.

Iowa Doctor Buys Aeroplane

Fort Dodge, Iowa.—Dr. F. C. Stahlee has purchased an aeroplane in order to enable him to make professional calls over the large expanse which his practice covers.

Aero Club of Pennsylvania Merge With Aviators' Club of Pennsylvania

Philadelphia, Pa.—The Aviators' Club of Pennsylvania, all of whose active members are fliers, has merged its activities with the Aero Club of Pennsylvania, through its president, Joseph A. Steinmetz. By this arrangement the new organization receives the membership, funds, club rooms and books located at the clubhouse of the Engineers' Club.

The active officers elected, all of whom are fliers, are: Captain Claude R. Collins, New York City Air Police, president; George S. Ireland, agent Curtiss Eastern Airplane Co., and Brooke Edwards, former army flier, vice-presidents; Charles W. Carvin, night flying instructor, secretary; Floyd Showalter, manager Essington School of Aviation, treasurer. Directors: John Bell Huhn, Murray Earle, George R. Brown, D. Willard Zahn and Sewall Cathcart. Mr. Richard J. Beamish, aircraft production expert, was made an honorary life member.

The club will be divided into two classes, fliers and non-fliers. Only fliers will be entitled to vote.

The club is pushing the establishment of a municipal aerodrome. It is hoped to obtain through legislation a piece of land about a mile square on the banks of the Delaware River as near to the center of the city as possible for an aerodrome.

Space around the edges of the field will be cleared, hangars built and leased to commercial enterprises at prices placed as low as possible. An aerial garage, machine shop, dope shop, service station and supply store will be conducted in conjunction, with skilled mechanics always at hand. The clubhouse will be placed at the disposal of the firms using the facilities of the field and no interference with any enterprise will be offered by the club. This will furnish commercial enterprises with the best possible landing field at a low cost, mechanics and repair service, and supplies without waiting.

The AIRCRAFT TRADE REVIEW

Buffalo Plant of Curtiss Company Increasing Output

Buffalo, N. Y.—The local plant of the Curtiss Aeroplane and Motor Company is said to be planning operations on a monthly schedule calling for 225 aeroplanes and 200 motors.

Glenn Martin Completes Passenger Carrier for Government

The Glenn L. Martin Company is completing the construction of a ten-passenger biplane on government order. It is expected that this type will be manufactured for commercial transport.

New York-Washington Aeroplane Passenger Service Planned

Washington, D. C.—According to a communication from the National Air Service Company, a regular passenger-carrying service between Washington and New York is to be inaugurated as soon as safe landing fields are established. It may be possible to obtain permission to use Bolling Field.

A service between New York and Boston is also contemplated and the chambers of commerce of both cities have been asked for information as to landing fields. The National Air Service Company is ready to start operations as soon as landing arrangements are completed, it is stated.

Aeroplane Mechanics School Starts in Spokane

Spokane, Wash.—The Modern Auto and Tractor School of this city is starting an aeroplane mechanics' school, as a result of the local interest in aeronautics. Sixteen thousand dollars' worth of equipment has been purchased. C. H. Messer, vice-president of the school, is in Detroit purchasing a Curtiss biplane and accessories. A pilot will be employed from among the local discharged men.

Five Courses Offered by Academy of Applied Aeronautics

Chicago, Ill.——The regular courses of the Academy of Applied Aeronautics which are being offered in addition to the two months' summer school course announced in our July 14 issue, are as follows:

Elementary Aeronautics: Three evenings per week for ten weeks. Elements of aerodynamic theory; calculations; principles of aeronautical motors; laboratory and wind tunnel experiments.

Aeronautical Engineering Course leading to degree of aeronautical engineer for college and technical graduates. An advanced engineering course.

Aeroplane Mechanics' Course, preperation for a position in commercial aeronautics. Theory, repair and inspection of aeroplane motors; principles of flight, rigging, tuning, repairing and inspection; housing and shipping of planes.

Post Graduate Course in Flying for graduates desiring flying experience. After qualifying for Aeronautical Engineering or Aeroplane Mechanics' Course.

Pilots' and Navigators' Course. A course leading to a pilot's license and a comprehensive knowledge of the science of aeronautics.

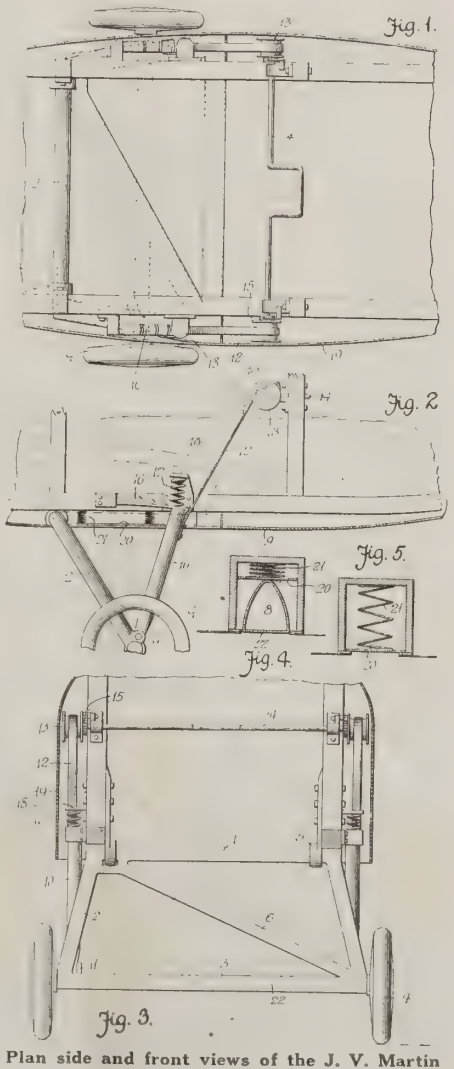
The school is conducted in a four-story fireproof structure with large and light classrooms, laboratories and rest rooms, conveniently located on the shore of Lake Michigan with direct transportation connections to all parts of Chicago.

Aerial Sightseeing Service Over Washington

Washington, D. C.—A group of ex-army aviators have organized an aerial sightseeing service over the city of Washington. A sixteen-mile flight from a field at Arlington in a Curtiss biplane will be regularly made for passengers every week day afternoon and all day Sunday.

The service is to be conducted by aviators recently released from the service, among them being W. W. Major, manager of the postal aviation field at College Park; Leon D. Smith, former pilot for the air mail service; Neal Angle, expert rigger from the College Park field, and D. S. Collier, of the air mail service.

RETRACTABLE LANDING CHASSIS PATENT GRANTED TO JAMES V. MARTIN



UNDER date of June 17, 1919, patent has been granted James V. Martin for an aircraft running and alighting device known as the retractable chassis. This invention relates to a landing gear which is arranged to be drawn up to the body of the aeroplane while it is in flight, thereby materially reducing head resistance. The device takes care of the absorption of running jars and alighting shocks. The construction also provides means for completely housing the device when the machine is in flight and when extended of closing the housings in such a manner as to present minimum wind resistance and not disturb the passage of air along the streamline of the fuselage when the recesses are not occupied by the alighting device.

The accompanying patent office drawings show some of the claims covered by Mr. Martin's patent. As shown in these drawings, a swinging frame is formed having a journal member (1) rigidly associated with end members (2) and outer members (3) to carry wheels (4) of any approved type. Bearing brackets (5) connected to the struts and longerons of the fuselage framework pivotally support the member (1), rigidity to the chassis frame as a whole being given by a single diagonal brace (6) which may be proportioned as shown, the parts 2, 3 and 6 of the chassis frame preferably having the cross sectional contour indicated in Figure 4 as the housed portion (8). The bearings (5) are so situated that the member (1) is at all times above the plane of the lower skin or sheathing (9) of the fuselage, and consequently is entirely out of the path of the air current.

Struts (10) are each journaled or pivoted, as at (11), to the frame members (2), adjacent to the wheel bearings and are held in upright position when the chasis is restracted, by flexible connections (12) passing over suitable drums (13) on a crankshaft (14) operable from the fuselage, a ratchet mechanism (15) holding the same at any point desired. When the device is lowered, the upper end portions of the struts (10) are snapped under spring members (16) of the leaf type, further shock absorbing means being had if desired in the form of upright spiral springs (17) in compression between the leaf springs (16) and a bracket member (18). The release of the ratchet mechanism (15) permits the momentary lowering of the struts (10) until they are clear of and fall to rearward of the latches, both because of gravity and because of the action of the wind in causing them to swing back.

The flexible connections (12) with their

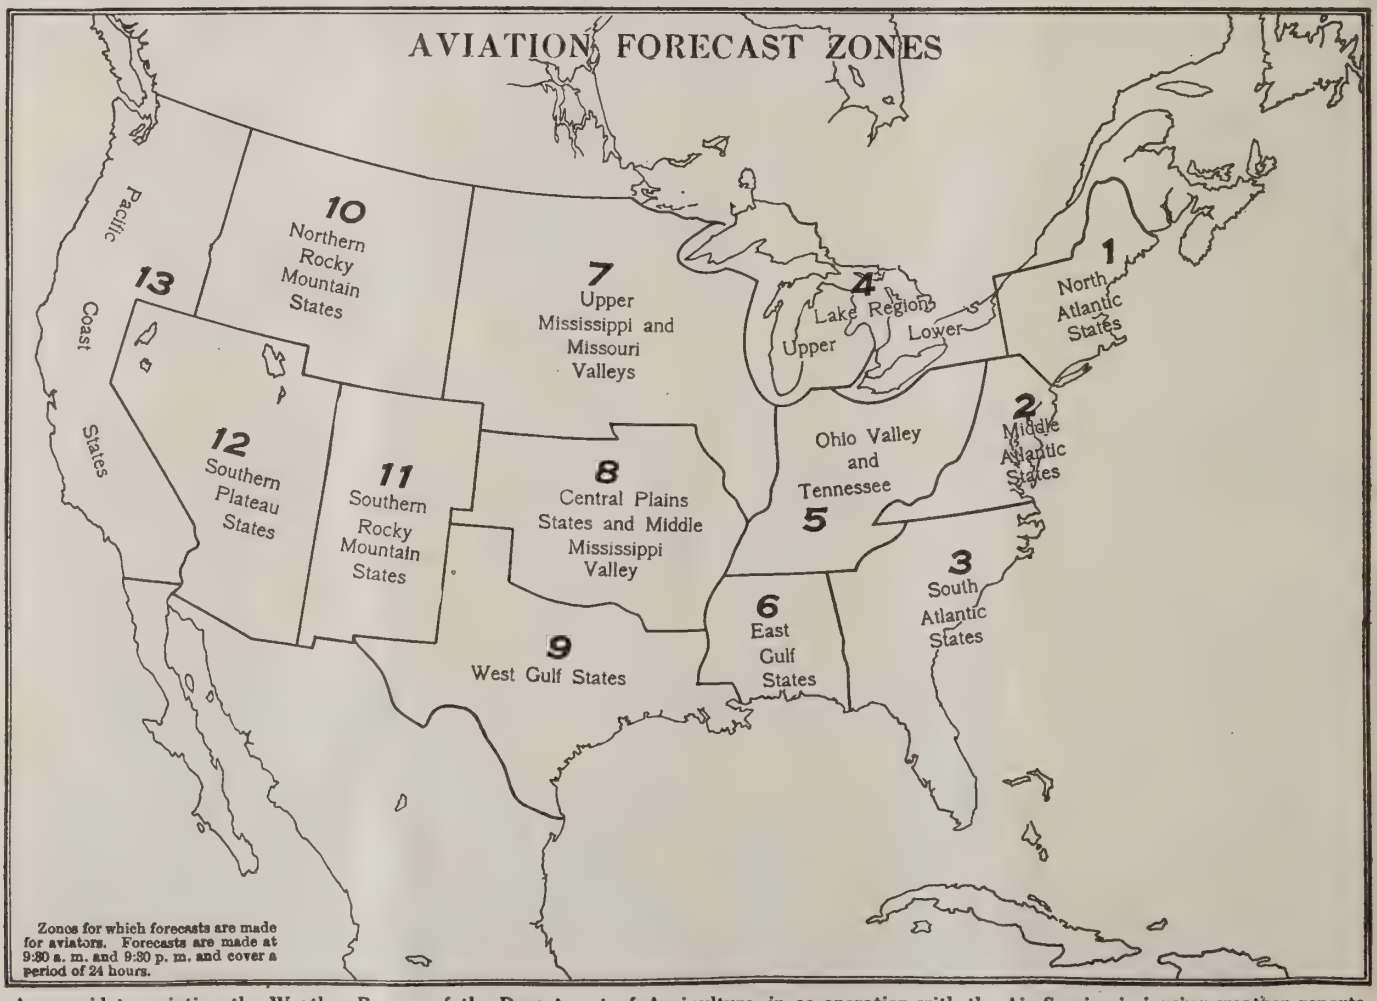
Aerial Mail Trip Between San Francisco and Sacramento

San Francisco, Cal.—Inaugurating the first aerial mail service on the western coast, Lieutenant C. C. Nutt, carrying Fanchon Wolft, a well-known San Francisco dancer as passenger in his De Haviland, flew from San Francisco to Sacramento in 45 minutes on July 31. The return was made in one hour. Two other De Havilands, piloted by Lieutenants E. H. Nelson and E. W. Killgore, accompanied the mail plane. The aviators are the members of the Ellington Field Squadron. The flight was conducted under the auspices of the San Francisco *Bulletin*.

Aerial Mail Service Between Canada and United States

The Aero Club of Canada has taken up with the Canadian Postoffice Department the matter of delivering mail between Toronto and Buffalo, Syracuse, Albany and New York during the international race for the Commodore prize of $10,000.



The establishment of an aerial mail service between the two countries is looked forward to with great enthusiasm by business men and has the endorsement of the chambers of comerce and civic organizations of Toronto, Hamilton, Welland, Albany, Syracuse and Buffalo.

Aerial Weather Forecast Service Improved

Washington, D. C.—The weather bureau of the Department of Agriculture has prepared a map of the United States, divided into thirteen zones, for which forecasts are to be made for aviators and balloon pilots. These forecasts are made twice daily, at 9:30 A. M. and 9:30 P. M., and cover conditions for the succeeding twenty-four hours.

Since July 21, forecasts have been made with the country divided into seven zones, with such satisfactory results that the number of zones has been increased to thirteen.

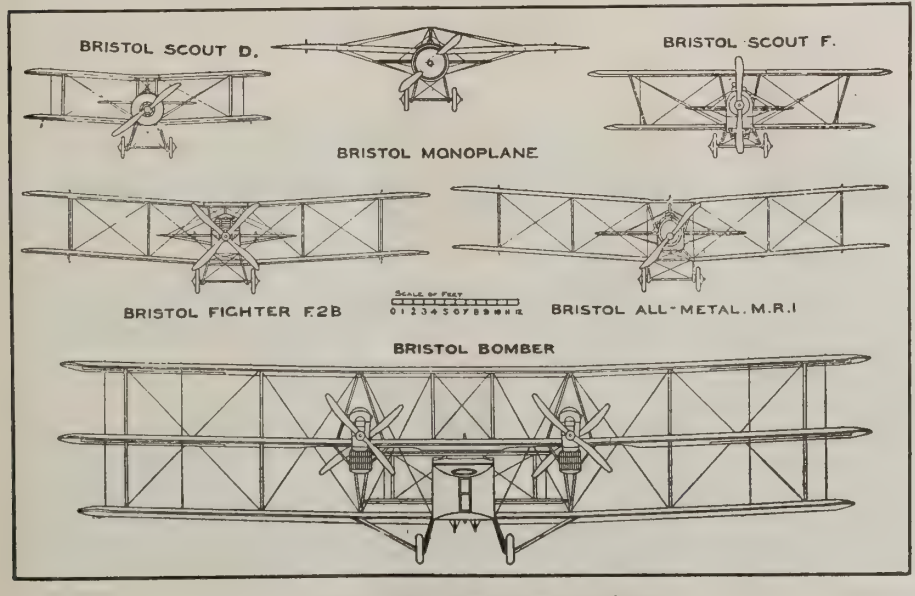
The Air Service has sent out the revised map to their active stations throughout the country and the forecast will be forwarded at the time made, it being intended that all cross-country fliers shall be advised of the weather conditions before starting on any contemplated flight, thereby reducing, as much as possible, to a minimum the liability of injury to aviators, balloon pilots, passengers and property, as far as weather conditions are concerned.

As an aid to aviation the Weather Bureau of the Department of Agriculture, in co-operation with the Air Service is issuing weather reports on meteorological conditions twice daily, which are available for civilian aviators. Map was prepared by Captain Charles J. Glidden, pioneer automobilist and aeronaut, who has just offered the Glidden Aeroplane Efficiency Trophy

THE BRISTOL AEROPLANES

AS one of the pioneer firms in the aircraft industry particular interest attaches to the products of the British & Colonial Aeroplane Co., Ltd., of Filton, Bristol, who commenced their career quite in the earliest days with "box kites" of the Farman type, later followed by more original designs by, in succession, Prier, Gordon England, and Coanda. It was, however, to neither of these designers that the honor of designing the "Bristol" war machines fell. This responsibility rested upon Captain F. S. Barnwell, R. A. F., who joined the firm as designer before the war, and produced, in collaboration, we believe, with Mr. Busteed, the little Bristol scout of pre-war days. The first of these machines was exhibited at the Olympia Aero Show of 1914. Later in the year a similar machine was flown by Lord Carberry in the London-Paris-London race. The first Bristol scout was not greatly different from the type D scout illustrated herewith, although there are certain variations as regards dimensions, etc.

Above—The Bristol Scout, Type F, with an air-cooled "Mercury" radial engine



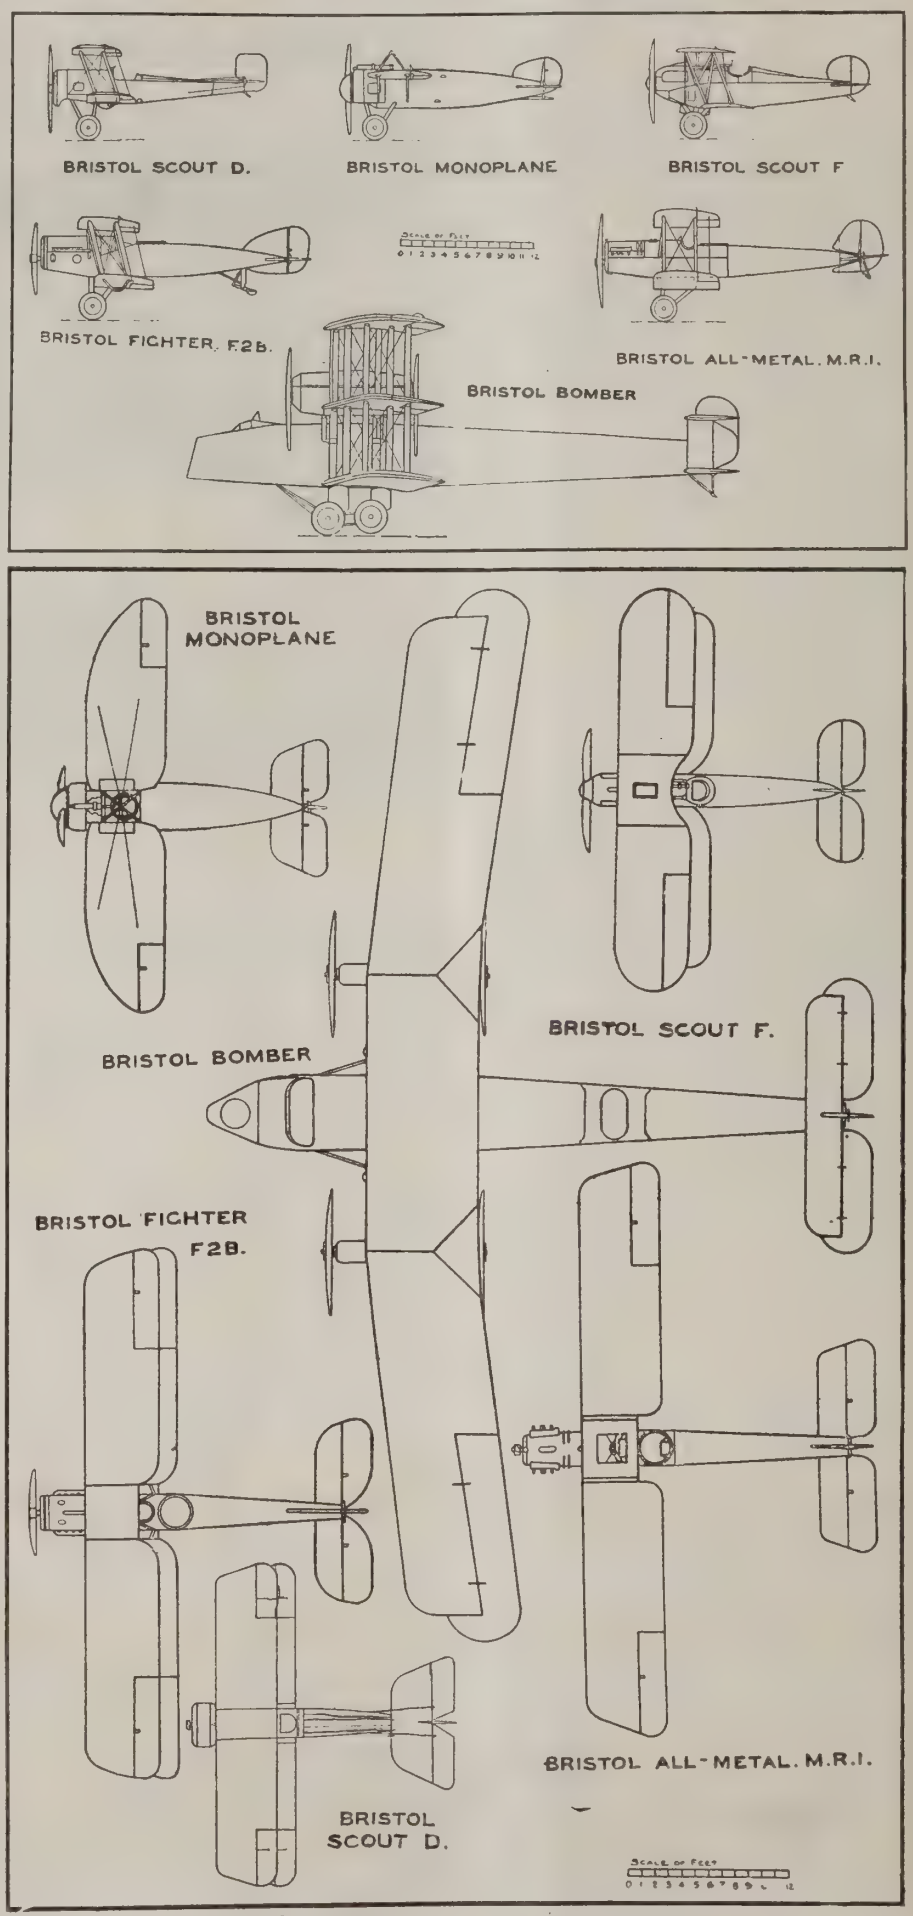
Below—The Bristol 170 h.p. Hispano engined all metal biplane

The Bristol Scout, Type D

The original Bristol scout had an area of only 156 sq. ft., whereas the type D shown in the accompanying illustrations has a total wing area of 200 sq. ft. In general outline the type D is very similar to the original Bristol scout, the rudder, tail plane and fins, as well as the body and main planes, being of almost identical shape. The body is somewhat deeper in front, and the cowling is slightly different, but otherwise the machine remains true to its prototype. Unlike several other makes of single-seater tractors, the Bristol has its wing bracing wires arranged in the plane of the staggered struts, a feature that has been considered undesirable on account of the extra drag stress it may impose on the internal bracing of the top plane, but in the case of the Bristol any such tendency is countered by fitting external drag wires running from the upper and lower ends of the rear interplane struts to the front of the fuselage. That this form of bracing is adequate would appear to be proved by the fact that to the best of our knowledge no Bristol scout has ever shed its wings in the air. Several variations of the Bristol type D have been built. With the exception of the fitting of different engines and minor alterations, they have not, however, been greatly different from the machine illustrated. To mention only one, there was the 100 h.p. Clerget-engined machine, which had a slightly different cowl, and had a rotating "spinner" fitted over the propeller boss.

The Bristol Scout, Type F

The development of the type D scout takes the form of a single-seater tractor, designed for a much more powerful engine than was the type D. In connection with the type F it should be pointed out that whereas the general arrangement drawings and the particulars in the two tables refer to a machine fitted with a 200 h.p. Sunbeam "Arab" engine, the machine sometimes has a slightly different arrangement, in which the nose of the machine is of different shape, owing to the fact that the engine is a radial air cooled, the Cosmos Mercury engine. In addition to the fact that it is fitted with a different engine, the type F Bristol scout shows variations in nearly all its other compoment parts, having, in fact, practically no resemblance to the original Bristol scout. Thus it will be seen that the type F has its lower plane of smaller chord and span than the top plane. The wing tips also are of different shape, while the various tail members are totally different in shape. Owing to the deeper nose and, generally speaking, greater side area in front, a fixed vertical fin is fitted in front of the rudder. The wing bracing is characterized by centre section and interplane struts of N formation, and the dihedral angle has disappeared. An examination of the accompanying table of performance, etc., is instructive. It will be seen that while the type D had a wing loading of 6.25 lbs. per sq. ft. and a loading of 14.7 lbs. per h.p., the corresponding figures for the type F are 8.08 and 10, respectively. The speed near the ground is 100 m.p.h. and 138 m.p.h., respectively, while the climb to 10,000 ft, occupies 18.5 mins. in the case of type D, and only 8.5 mins. for the type F. It is thus seen that it would appear that "performance" is far more a question of load per h.p. than it is one of wing loading, and that it is in fact only the question of a reasonably low landing speed which prevents one from employing a much higher wing loading than is generally found.



Front views of the Bristol aeroplanes

The Bristol Monoplane

With the exception of the very earliest days of the war, there has been, at any rate in Great Britain, a remarkable absence of aeroplanes of the monoplane type. Some of the first machines to go out were, it is true, of this type, as for instance the Bleriots and Moranes, but before many months of war had passed the biplanes were rapidly supplanting the monoplanes, and during the last two years of war the monoplane was hardly if ever seen. This may appear somewhat strange, especially as the monoplane has undoubted advantages for fighting purposes, giving as it does a much better view forward and upward. Especially is this true of the "parasol" type of monoplane in which the wings are on a level with the eyes of the pilot, but for some reason or other the type has not found general favor. Special interest, therefore, attaches to such few monoplanes as have been built during the war, among which is the Bristol monoplane. This machine, it will be seen from the accompanying illustrations, is of very pleasing appearance, with its stream-line body and crescent-shaped wings. Efficiency is the keynote of its design, with head resistance reduced to a minimum. Thus the wing section employed is such as to allow of very deep wing spars which are capable of taking care of their load with a minimum of external aid, in the shape of one wire to each spar. Lateral control is not by means of wing warping, as was the general practice in monoplanes before the war, but by ailerons as in the biplanes. This form of lateral control is probably chosen in view of the deep wing section, which would tend to make a comparatively rigid wing structure difficult to warp and liable to excessive strain if warping were employed. In order to give the pilot a better view downwards—forward and upward is already as good as it is possible to make it—openings are provided in the inner portion of the wings, near the sides of the fuselage, and one is inclined to think that in this respect at least the Bristol monoplane is able to hold its own against any conceivable biplane combination. As regards performance: from the table it will be seen that near the ground the monoplane is capable of a speed of 130 m.p.h., which is distinctly good for an engine of only 110 h.p. At 10,000 ft. this speed has dropped to 117 m.p.h., which is not bad considering that the engine is a rotary. The climb also is quite good, the first 5,000 ft. only taking 3½ mins., while 10,000 ft. is reached in 9 mins. As the landing speed is certainly not unduly high, it appears that taking it all round, the monoplane is able to hold its own against the biplane for performance, and there can be no doubt that as regards visibility the monoplane has it all its own way. For peaceful purposes we are not at all certain that the last has been heard of the monoplane type of machine.

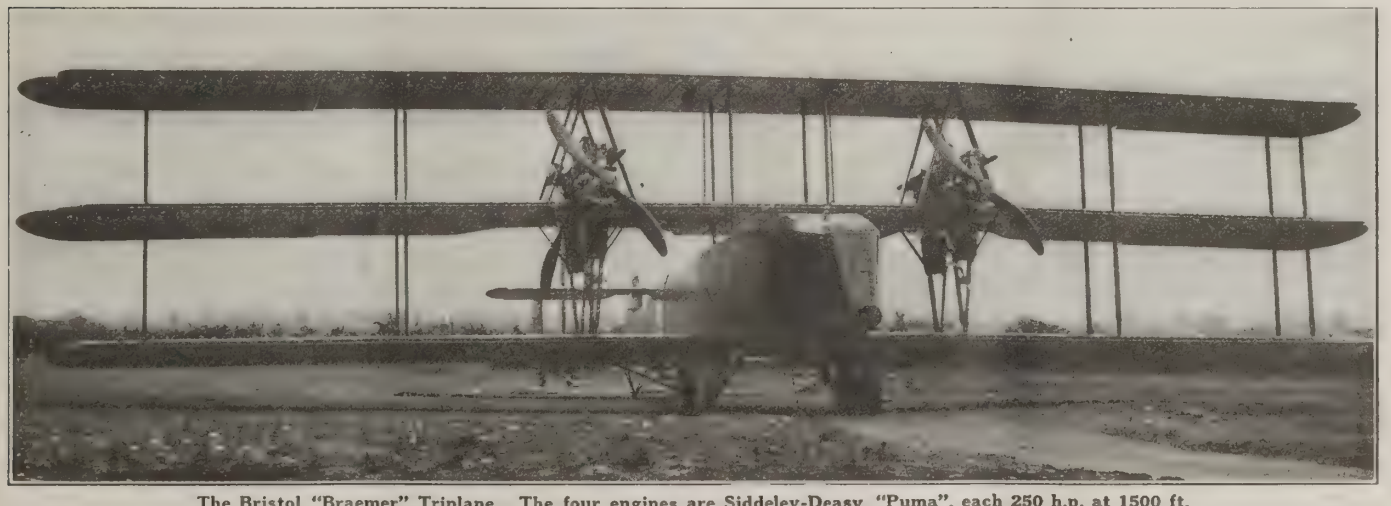
The Bristol Fighter

Probably the best known of the Bristol products during the war is the Fighter (F2B). This machine has been extensively used for fighting, reconnaissance, etc. The impression one receives on examinating the F2B is that it was designed in the first instance for the purpose for which it was intended, and not merely designed from the aero-dynamical point of view and afterwards rigged up for certain purposes for which machines happened to be required. There is a decided

Plan and side views of the Bristol aeroplanes

difference between the two methods. Thus it will be observed that the designer quite evidently had in his mind to provide as free a field aft as possible, and to this end he chose to flatten the fuselage out to a horizontal knife edge, bringing the various tail members down lower out of the way of the gun. Also the flat top of the body bears evidence of this intention. Again, it was desired to place the gunner and pilot high in relation to the top plane, and to do this would have meant, with the ordinary arrangement, a very deep body with consequent large maximum cross-sectional area. To avoid this the lower plane is not attached to the body, but runs right underneath and some distance below the bottom of the fuselage. This arrangement has resulted in a somewhat more complicated undercarriage attachment, but, everything considered, there is little doubt that it has been worth while.

From the table it will be seen that the performance of the F2B with Rolls-Royce "Falcon" engine is very good indeed. A feature of this machine which will not be found in the table and which cannot be put in table form owing to the absence of any standard of comparison is the excellent stability of this machine. We are informed by pilots that although she is not in the least sluggish on the controls the Bristol Fighter is endowed with a remarkable amount of inherent stability, which renders her particularly easy to fly. It would, therefore, appear that Captain Barnwell has managed to find the solution to the problem of good stability combined with ease of control, a fact which should be extremely valuable for post-war aeroplanes.



The Bristol Fighter, equipped with a Rolls-Royce or Hispano Suiza engine

The Bristol "All-Metal" Biplane

From the earliest days of aviation the question of wood versus metal construction has been the subject of discussion, and both methods have had their supporters. Up till the present, however, the wood construction has been predominating, at any rate in Great Britain. Particular interest therefore attaches to the few examples of the metal construction method that have been built. Among these is the Bristol type MRI, shown in the accompanying illustrations. It will be seen that although the All-Metal machine is of somewhat larger dimensions than the Bristol Fighter, the loaded weight of the two machines is practically the same. Against this must be put the fact that the MRI has a 170 h.p. Hispano engine, while the F2B has a 260 h.p. Rolls-Royce. The All-Metal carries, however, slightly more fuel than does the B.F. The loading per sq. ft. is somewhat smaller for the larger machine, but the load per horsepower is considerably greater, thus accounting for the fact that the MRI has not so good a performance as the F2B. It might be added that the weight, empty, of the B.F. is 1,750 lbs., and that of the MRI 1,700 lbs. It may, therefore, safely be concluded from these particulars that there is no reason to suppose that an all-metal aeroplane cannot be built as light, or nearly so, as one constructed in the ordinary way of wood. There can be little doubt that for use in tropical climates, such as will be encountered by the post-war commercial aeroplane, the metal construction will be better able to withstand the changes in temperature than will one built largely of wood, and while we should not care to assert that the days of wood construction for aeroplanes are over, we do think that metal construction will be more general in the future than it has been in the past.

The Bristol Triplane

While for her largest machines Italy has to a great extent pinned her faith in the triplane, as instanced by the large Caproni triplane bombers, there has been in Great Britain a tendency, rightly or wrongly, to adhere to the biplane type, even for very large machines. That excellent results may be obtained by the biplane form has been amply demonstrated

The Bristol "Braemer" Triplane. The four engines are Siddeley-Deasy "Puma", each 250 h.p. at 1500 ft.

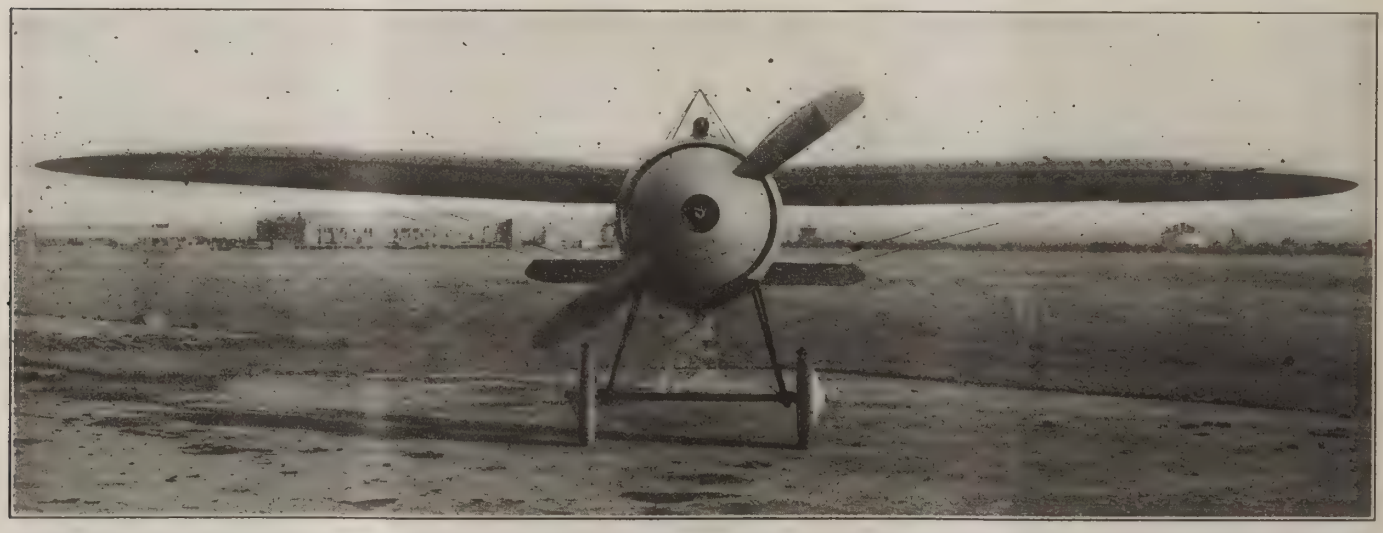
by the large four-engined Handley Page, but it may be doubted whether the triplane form has been as extensively tested as it deserves. The object of the Bristol Bomber was to provide a high-speed machine for bombing or passenger carrying, capable of lifting a considerable load in addition to the weight of crew and fuel. The "Braemer," as the Bristol Bomber is called, is driven by four Siddeley-Deasy "Puma" engines, developing a total of 1,000 h.p. at 1,500 ft. Two of the engines drive tractors while the other two drive pushers, after the manner of the large Handley Page. The two tractors have a diameter of 9 ft. 10 in. and a mean pitch of 6 ft. 11 in., while the diameter of the pushers is 9 ft. 2 in. and the pitch 7 ft. 2½ in. The two pilots' seats are placed side by side in the fore part of the body, some distance ahead of the leading edge of the planes, while the extreme nose of the fuselage is occupied by a gunner. Well aft in the body is another cockpit with two guns mounted on a turntable, while a fourth gun is mounted on another gun ring in the floor of the fuselage. The machine is thus well capable of looking after herself as regards defensive gun arrangements. The following instruments are carried:

On dashboard: 2 air speed indicators. 4 radiator themometers, 4 revolution indicators, 4 Liberty switches and voltmeters, 1 switchbox for electric lighting, 1 altimeter, 1 cross level, 1 watch. Electric lighting set for each instrument.



Below dashboard: 1 compass.

In forward compartment: 1 air speed indicator, 1 altimeter, 1 high altitude bomb sight. These are for bomb dropping.

Rear of pilot's seat: 1 air speed indicator, 1 altimeter, 1 gyro bomb sight. Flowmeters for petrol. These are for bomb dropping.

On engine housings: 4 oil pressure gauges.

The weight of the machine empty is 9,300 lbs., and she carries 400 gallons of petrol, 40 of oil, and 30 gallons of water. After allowing 360 lbs. for two pilots, the machine is still capable of lifting another 3,000 lbs., bringing the total loaded weight up to 16,200 lbs. The wing loading, it will be seen, is fairly high, 8½ lbs. per sq. ft., and the load per horsepower is 16.2 lbs. The speed at ground level is 106 m.p.h., which is not bad for such a large machine, and the climb to 10,000 ft. only takes 35 minutes. Naturally the performance cannot compare with that of the smaller machines, but for a weight lifter it is not by any means poor, and the machine might make a good commercial aeroplane for carrying large loads.

The Bristol monoplane makes a speed of 130 m.p.h. with a 110 h.p. Le Rhone engine

SOME PROBLEMS IN THE DESIGN OF WOOD PROPELLERS

Relative Value of Different Woods. Advantages and Disadvantages of Different Methods of Blade Tipping

By LESLIE V. SPENCER, M. E.

IT is safe to say that no part of the modern aircraft has been given more attention from the design and construction standpoints than the propeller. Yet, in the majority of cases, there is perhaps no unit of the ship that gives more trouble. There are so many things to be taken into account in making the stick, and so many different types and species of woods that can be employed, that development and research work on this part alone occupy as important a place in aeronautical engineering work as is given to the design of the engine or of the plane itself. Not only that, but after the propeller is constructed, very elaborate precautions must be taken to maintain it at a constant moisture content when in storage, else warping and cracking or parting of the laminations will result, rendering the screw of little value from the service viewpoint. In addition to all this, some means of covering or sheathing the blades is most advisable to protect them against tall grass, water spray, pebbles and the like, all of which are enemies of the rapidly revolving blades.

When it is further considered that any given shape and size of propeller is usually suited to only one design of plane, necessitating a different screw for each type of plane, it will be seen that the flying field having several different models or types of planes in its equipment will be confronted with the problem of storage for a large number of different shapes and sizes of propellers.

Propeller Woods

A great many propellers of nearly every practical species of wood have been whirled to destruction at the propeller testing laboratory at McCook Field, and from the results obtained, it appears that oak is the most satisfactory wood for propellers from the standpoint of strength. Where screws made of many other woods could not withstand the required whirling speeds used in the tests, the oak propellers in nearly every instance underwent the tests without breaking.

Walnut has proved itself almost the equal of oak, and where properly designed, propellers of this wood are undoubtedly entirely satisfactory. Walnut, however, is harder to obtain with satisfactory grain than oak, so that, all things considered, oak has a shade the advantage.

It must be remembered that this refers only to the strength characteristic of woods. In some instances the weight of the wood must be given great consideration, and as both walnut and oak are heavy woods, they might not always be most desirable, everything taken into account. In general, in selecting the wood for a given type of propeller, account must be taken of the tendency to warp, the weight and the strength, so that simply because a wood is very strong is not conclusive evidence that it is desirable.

Another very satisfactory propeller wood is Honduras mahogany, and while many species of mahogany have a tendency to split or warp, this variety seems well suited to propeller work. The average run of commercial mahogany, however, does not appeal to be very well adapted to propeller making for lack of strength. African and Philippine mahogany is not very highly regarded for propellers because of this cracking and warping habit under load. Perhaps these differences between the various species of the wood are due in large measure to the fact that mahogany as a designation

Figure 1

Cross section of a flat sawn blade. The use of quarter-sawed wood would result in more nearly parallel growth rings

for woods is a much abused term, in that the characteristics of the different types vary widely, so much so that it is often considered that many species of woods that go under the name of mahogany are in reality not mahogany at all, but very likely some related wood having somewhat the same appearance.

Cherry is another wood that has given highly satisfactory results in the construction of most standard types of propellers. The wood possesses great strength, and has a certain elasticity or "give" to it that is often a desirable feature, especially in certain designs of screws.

Poplar and spruce are good woods for the ordinary propeller shapes, although not recommended for sticks that are of a design which has a tendency to fluttering at high speeds. Spruce is comparatively

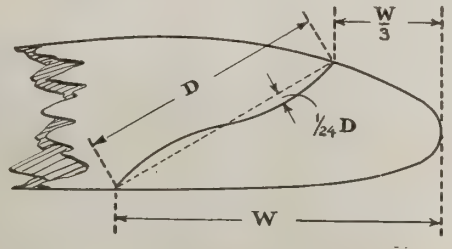


Figure 2

Dimensions of a good type of brass tip for ordinary service conditions

weak in tension (weaker than oak, walnut or mahogany).

Prima vera has also been experimented with, but it is not very highly regarded for propellers. Being a very hard and dense wood, it is heavy, and its hardness leans to brittleness, which often has resulted in cracking under test loads. It is possible that there is not enough elasticity to the material to take care of sudden applications of heavy loads, and as prima vera does not appear to have advantages that many domestic woods have, while at the same time it possesses several disadvantages, it does not appear to merit much consideration for the purpose.

There are, of course, various combinations of woods that have proved very satisfactory in the construction of propellers, such as mahogany and walnut, oak and cherry, etc.

Quarter Sawing

With the object of reducing warping and curling of the blades, it is advisable to use quarter-sawed laminations in preference to flat-sawed pieces, this applying more particularly to our domestic species of woods. Where flat-sawed material is employed, usually the direction of the growth rings in the several laminations is such that unequal warping results from variations in the moisture content. The illustration, figure 1, shows a cross-section of a blade made from flat-sawed stock, which brings out the point. The tendency to warping could have been greatly reduced or eliminated by employing material having these growth rings running in approximately parallel lines.

Methods of Blade Tipping

No process of tipping the blades of propellers (particularly the leading edges) has as yet been devised that is entirely satisfactory from all standpoints, although the development of the use of such materials as pig skin, linen and cotton has been very satisfactory as a whole. These coverings have shown good results where sand and gravel and long grass are encountered, as well as proving quite satisfactory as protection against wet grass, rain and water spray under moderate conditions of exposure. But where the propeller is subjected to severe service conditions, such as the necessity for coping with long or tough grass, gravel, flying chips and water spray, metal tips of copper or brass are as yet the only means of protection that have met with any degree of success.

It might be well here to draw a distinction between the tipping or covering of blades for the purposes above mentioned and the coating of propellers by any one of the several methods now practiced for protecting against moisture. The most generally used process for moisture exclusion is by coating the entire screw with aluminum leaf, this usually being put on over the regular tips that are applied for protection against abrasion. Thus, while an outer coating of this kind is often applied, particularly where a propeller is to be in storage for any length of time, it is not intended as a guarantee against chewing or wearing of the blades, but is merely a moisture-proofing scheme, and is to be distinguished from the protective tips.

Copper and Brass Tips

There are two classes of service for which the metal tips of copper or brass seem to be the only kind suitable. These are training planes and seaplanes or flying boats. With the watercraft, it is evident that the greatest protection must be afforded against the constant water spray when the seaplane is on or close to the

water surface, and nothing short of a metal leading edge seems to be satisfactory. With training planes, due to the service they perform, the propellers are of necessity given very severe usage, since the plane must do a great deal of taxi-ing and warming up of the engine. About half the time that a training plane engine is running the ship is on the ground, which means that the propeller of such a plane is subjected to abrasion from one cause or another to a very much greater extent than that of a plane in regular service, since the latter is usually in the air a good share of its engine's running time.

It is true that at most training fields, measures have been taken to protect the screws as much as possible by having wooden platforms or concrete pavements on which the planes are run whenever the engine is to be operated for any length of time on the ground. This, of course, reduces the chances for abrasion from the picking up of loose matter, but it is of no value as soon as the plane is put through taxi-ing manœuvers such as required to give the student a working knowledge of the ship before it goes into the air.

Earlier difficulties with the heavy metal tips are now in a large measure overcome by accurately locating the holes in the metal so that the attaching rivets or screws will be in exactly the same positions with respect to the two blades, thus preserving the balance of the propeller, and also by carefully staggering and locating the rivets or screws so that there is less tendency to split the wood and to pull loose due to the high centrifugal forces set up in operation.

Of course, the metal tip is not satisfactory for the very light type of propeller which tapers down to quite a thin tip. It is very difficult to attach the metal tip to such a blade without the screws splitting the thin wood or pulling out when the propeller gets in service. Further, the light blade is prone to fluttering excessively when metal covered, a disadvantage that soon means cracking of the wood or of the tip or both. The propeller must have sufficient body to form a satisfactory "anchorage" for the metal sheathing, which limits this kind of tipping to the heavier sticks such as used on seaplanes, large service machines and most training planes.

An important consideration in the use of metal tips is the lapping. There have been many instances where poor soldering or improper position of the seam have resulted in the tips pulling loose or opening up in service. It is best to have the lap at the leading edge, the metal being carried around on either side of the edge so that there is a double thickness at this point. The seam should be on the back face of the blade. The English specifications call for a lap on either side of the edge of 11 millimeters, and this has proven quite satisfactory. In American practice, about ⅜ inch is best.

As to the matter of screws or rivets, the general rule is to use one brass screw per square inch of metal surface, or one copper screw per 1½ square inch of surface. The screws should of course be staggered as referred to the front and back faces of the blade, and they should also be carefully positioned with respect to the grain of the wood so as to eliminate as far as possible chances of splitting from striking the grain improperly. This especially applies to the screws at the outer ends of the blades.

In designing metal tips, care should be taken to bring them well in toward the hub on the leading edge, the trailing edge being more or less unimportant, except in the vicinity of the tip. It has often been found that, where the length of the tips on the leading edge was inadequate, chewing would take place along that portion of the edge from the tip in toward the hub, where otherwise the blade was all right. The length of the tip should be anywhere from one-quarter to two-thirds the length of the blade, the exact distance being dependent upon the kind of service for which the propeller is to be used, etc.

A typical form of a brass tip is shown in figure 2. This tip is best made of 24-guage material, and there should be 114 screws in each face of the tip, these screws being ⅜ inch No. 4. Such a tip would ordinarily be suitable for a service plane or a training machine subjected to moderately hard usage.

Referring to figures 3, 4 and 5, some typical cases of tip failures are illustrated. In figure 3 the blade was too thin for the tip and the resulting flutter cracked the wood, as can be seen, with the end of the metal sheathing finally cracking off. Figure 4 indicates what happens to a metal tip when coming in contact with a stone or pebble of fair size. This tip was struck on the leading edge by the stone, and the metal was split in several places as a result. Figure 5 illustrates a case where the tip has pulled away about ¼ inch due to centrifugal force or looseness of the attachment. This might be the result of using the wrong kind of screws or rivets, or from not correctly spacing them.

Cotton and Linen Tipping

Although cotton and linen will not, of course, give the tips as much protection

PRELIMINARY NAVAL FLIGHT INSTRUCTION

By NICHOLAS S. SCHLOEDER

(*Continued from page* 1016)

Turns

TURNS which are comparatively "safe" can be made in great variety, but an exactly correct adjustment of bank and curve can only be executed by exercise of much care. In most turns, the pilot either skids or slips. Skidding outward results from too little "bank," which compensates for centrifugal force; or conversely stated, too much "fudder." Slipping inward is the result of excessive bank, the centrifugal force being insufficient to keep the machine in its normal trajectory. Usually the skid or slip is very slight, but a student should strive to make his turn as nearly perfect as possible.

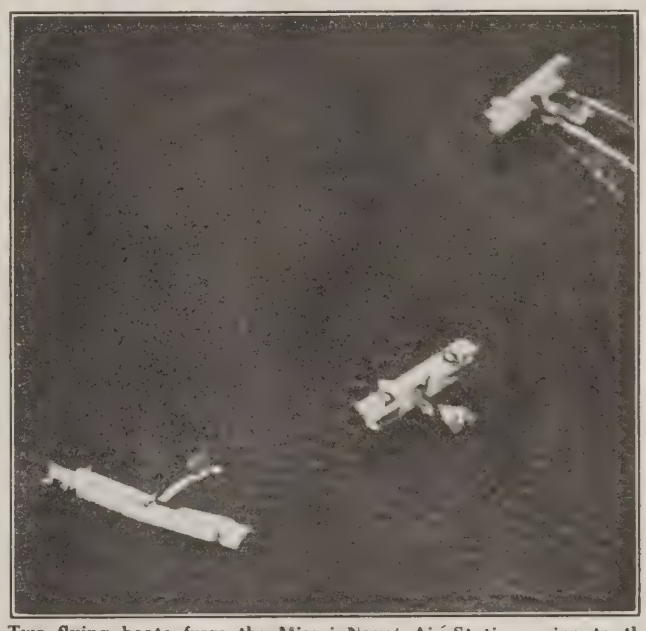
Certain suggestions will assist a student in a proper adjustment of controls. First of all, it is usually necessary to depress the nose to make up for loss of speed on a turn. In relation to this, overbanking has a tendency to raise the nose, as skidding has to depress it. Another point to remember is that students invariably begin turns too vigorously, the cause of nearly all imperfection in turning. To make embryo aviators feel their turns is the subject of much vain pleading on the part of instructors. Lastly, the proper sequence in the use of the various controls is very important. Though theoretically, all controls should be used at once, the following empirical rules for students should be helpful. Firstly: Use elevators to depress nose slightly. Secondly: For left-hand turns aileron to moderate bank, and lastly: Apply rudder. For right-hand turns, aileron and rudder may be applied simultaneously.

The difference between turns to the left, and right, is due to the action of torque. Though any tendency to confine one's self to a habitual turn one way or another should be discouraged, yet it must be learned that greater care is exercised in all evolutions to the left. Skidding is far more common on left turns because a student forgets that torque alone is sufficient, and therefore by ruddering even slightly to the left, excessive rudder action results. Positive left rudder should never be applied unless a sharp turn is desired, in which case the bank must be correspondingly steep. For moderate turns to the left a release of the customary right rudder is sufficient.

A student must learn by feeling. Wind on the side of his face will assist. Wind pressure felt on outside denotes a skid, on the inner side, a slip. Of the two, skidding is more objectionable and far more common. For all altitudes above a few feet, it is a more unstable condition, implying the use of excessive rudder, which on left turns where a tendency to stall exists, directly invites a spin.

To illustrate this point, a common method of spilling follows a course something like this: A student has a low-powered machine, we will assume. He is close to the water and is about to make a turn. He is anxious to "get around," we will say. He applies hard rudder. The machine skids, as considerable bank is necessary to compensate the centrifugal force outward, which of course, the student fails to execute. Now the machine, moving as it does, sideways as well as forward, thereby loses some of its lifting power and consequently settles. The student now becomes alarmed, fearing that he will strike the water before completion of his turn. He instinctively pulls back his elevators, hoping to raise himself. What has resulted? He is now in an ideal position for a spin—rudder hard over, elevators pulled back. A bump sends the nose up, and—over he snaps, tail up, outer wing lifted, hitting the water at an oblique angle. Some one on the beach shouts "sideslip!" which is once more incorrectly held responsible; whereas in fact, it was nothing less than the first part of a spin, due originally to a skid.

If a student is taught to begin a turn cautiously, it is not necessary to impress upon him the need of aileroning and ruddering against a turn after it has been begun, upon the theory that it takes more control to start a turn than to maintain it. This is largely true only of sharp turns. Too much control at the start with subsequent correction, is responsible for the jerky, slovenly turns, alternately steep and flat, nose up and down, so characteristic of beginners.



Getaways

The getaway or take-off includes three distinct phases, fundamentally the same on all machines, though differing considerably in the length and degree of each phase. They are, in order, raising the nose of pontoon or hull clear of the water; throwing the pontoon on the step over the surface of water, and finally, planing on the surface of the water until flying speed is attained and the machine takes the air.

The purpose of the first phase is to clear the nose of machine from interference by waves. The elevators are pulled back to the chest. However, in smooth water, this is unnecessary. Indeed, it is desirable to hold elevators in neutral whenever the sea permits.

To force a machine out of water and on the step, the yoke is thrown forward when the nose of the pontoon has reached its maximum height, and so held till the nose slowly drops as the machine climbs on the step, when the elevators are gently pulled back to neutral. Considerable pressure is often required to hold the elevators forward, though in some machines, as the Curtiss R's, the machine climbs on the step of its own accord.

Many beginners experience difficulty in knowing they are planing on the surface. The fall of the nose and increased speed are certain indicators. If the student is slow to discover this and continues to hold the yoke forward, violent "porpoising" or rocking forward and aft will result. The student should under no circumstances attempt to combat this by moving his elevators backward and forward. Simply pull back gently to neutral as before noted, and the "porpoising" stops at once. Sometimes the pilot pulls back too far, so that the machine jumps off the water momentarily, before attaining air speed, a condition closely approximating a true porpoise. This is very common in H-boats and R's, and the student must learn to distinguish between it and a true porpoise, which is always the result of controls held forward of neutral.

Two flying boats from the Miami Naval Air Station going to the rescue of a student flyer who made a bad landing

Difficulty will be experienced in putting a machine on the step whenever the engine is failing. Many devices are used in such cases. Some endeavor to rock it on; that is, by jerking yoke forward and back, they hope literally, to throw it on. This is a common fallacy. This motion constitutes a drag and hinders rather than helps by resultant reduction in speed. Whenever a machine must be "put" on the step, the controls should never be held more than two-thirds of the maximum distance in front of neutral. Rocking is advisable only through a slight arc about neutral. I have found that an arc from neutral to slightly in front of it is the most effective; any greater radius is absolutely fallacious. Sometimes a slight rudder and aileron action is helpful to overcome the chance of a vacuum having been established behind the step.

All other methods fail where the shallow water method will succeed. Running through water having a maximum depth of about three times the draught of the machine, to a minimum depth equal to its draught, is unfailing where the machine will fly at all. The water, having no chance to escape, piles up in front of the bow of the pontoon, so that the fulcrum moves far back to the rear of the pontoon and with this additional leverage the machine easily attains the surface.

The final phase, the take-off, presents no special difficulties. The controls are held in neutral as the machine skims over the surface until flying speed is attained, when it takes the air without assistance. A machine should never be dragged off. Care should be taken to keep the wings level, otherwise a wing tip pontoon will bury itself in the water, causing the machine to swerve. Only with R's are the elevators held back of neutral in the take-off; they are neutralized at once upon clearing the water to prevent stalling. This tendency to stall is a common error. Students must not be too anxious to climb; this will take care of itself, and will certainly not be assisted by stalling.

The getaway is always into the wind, unless as on the high seas, when it is sometimes advisable to run parallel to the waves. To keep a machine into the wind, hard rudder is frequently necessary, especially where a wing tip pontoon has caught in the water. Failure to keep into the wind is the chief failing of students. Learn to keep the wings level and use rudder actively, which is necessary to take-off in a neat direct course into the wind.

Landings

Landings are the bane of most preliminary students, who are inclined to exaggerate their importance and difficulty. The principle part of a landing, briefly, are the glide, first point of leveling off, final point of leveling off, loss of flying speed, the squash, contact with water and final penetration of water. Landings may be conveniently divided into two kinds, differing slightly in the relative time and place of these phases, and are variously called speed or step landings, and stall, squash or slow landings.

On all machines save F-boats, it is not particularly advantageous to assume a gliding angle before the engine is throttled. The disadvantage of this practice results from the racing of the engine. The best practice, perhaps, is to make this throttling simultaneous, using the right hand to slowly cut the power, while the left moves the yoke forward. The correct gliding angle should be assumed at once, the student adjusting his controls accordingly, after which he must strive to hold it until the time for the first point of levelling off is reached. The right rudder must be taken off during glide. Failure to do this is a very common fault. Many instructors exaggerate the importance of a steep gliding angle. Notice, I speak now of the glide to a landing, which should always be straight into the wind from an altitude of not less than two hundred feet. In such cases, favorable conditions are prime, and the dangers of flat glide are absent. These exist only in and from spirals, etc., where the rudder is out of neutral. Remember, spins do not occur with neutralized rudder, and "slips on one wing" only through positive stalls. Moderate glides are best for beginners, as it aids them to find the water and so shortens the period of instruction. However, the student should learn to glide steeply as soon as he can land, as speed is the best insurance against adverse air currents just above the water.

The second phase, the first point of leveling off, occurs between fifteen and twenty-five feet up. The elevators must be gently withdrawn, otherwise the pilot will find himself in horizontal position before he is within striking distance of the water.

Indeed, this movement should be so regulated that the third phase, the final point of leveling off, should not occur at a greater distance than about three feet above the surface of the water. When this occurs directly at the surface, the landing is said to be fast. Thus, the position of this point determines whether the landing is step or squash, and the sequence of subsequent phases.

The fourth phase, loss of flying speed, occurs simultaneously or after contact with the water in a step landing. In slow landings, immediately follows the completion of the third phase, which, occurring above the surface, involves another phase non-existant in step landings. This is the squash or stall.

A machine which is maintained in horizontal flight without power soon loses its flying speed and settles rather precipitately. Now, as the machine drops suddenly on the water, it is important to make the contact such as to minimize the chances of breakage, as well as to prevent a rebound. This is accomplished by a quick withdrawal of the yoke which stalls the machine and makes contact on the rear of the pontoon back of the step. Thus a sharper edge for settling on the water is presented, thereby preventing a bounce, while the greater penetration of the water acts as a cushion to prevent breakage. More important still, the tail landing implies a maximum angle of incidence, which markedly increases lift, and thereby arrests the suddenness of squash and force of contact.

The last phase, final penertation of water, occurs after contact with water in step landings. In coming off the step no difficulty is experienced save in R's, when a tendency to porpoise exists. Throwing the yoke forward is the quickest way to arrest this.

The diagrams, Figures 1 and 2, illustrate the difference between fast and slow landings.

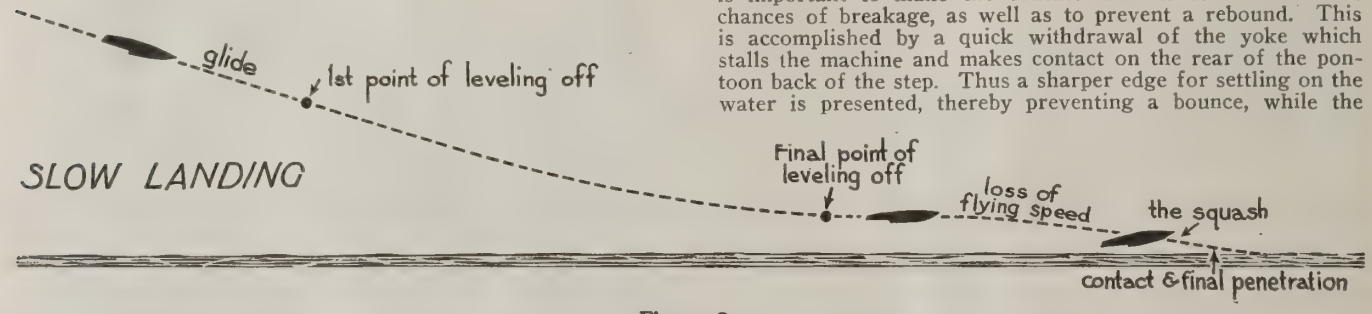


Figure 2

Diagram showing how the machine manoeuvres in a slow or "squash" landing

Slow Landing

In stopping for a moment to consider relative advantages of each type, it might be stated that step landings are not taught preliminary students. It will be readily seen that if the final point of leveling has occurred before contact, the pontoon will strike on its nose with great force, thereby either "nosing in" completely, or rebounding again to ten feet or more, where it will again be necessary to open the throttle and proceed, as recovery otherwise is very difficult for beginners. Squash landings, on the other hand, have a margin of safety.

The point of original leveling does not present special difficulties, as most students fix this within the proper attitude. However, there is a tendency to pull back too much, so that the leveling off process is completed too soon. In that event, it will be necessary to throw the controls forward again. This forward and backward movement of the yoke is known as "fanning," and it is more or less essential to beginners. With experience, the degree to which fanning is done is minimized, so that it is practically imperceptible, but all fliers, however experienced, "fan" their approach.

If students experience difficulty in approximating their distance from the water, in nearly all cases this is because they

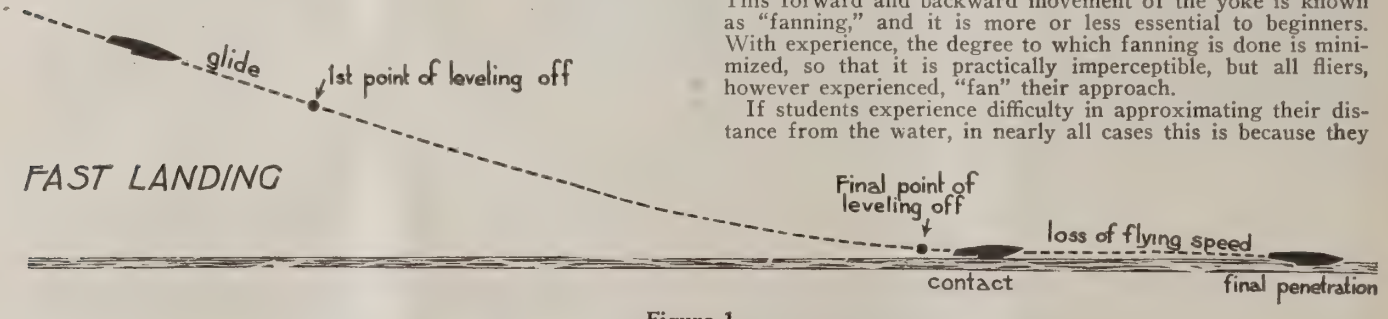

Figure 1

The path taken by a seaplane in making a fast or "step" landing

look directly beneath them. They should look as far ahead of the lower wing as their vision permits.

The point of final leveling off presents greater difficulties. The student places this at the proper height, but fails to maintain it because he permits the machine to ascend once more. This is termed "leveling off too much," as distinguished from "leveling off too high." Figures 3 and 4 give illustrations of this difference.

Leveling off too much is the more common fault. To combat it the student must learn to act quickly and throw his control forward the moment he finds himself once more ascending, always remembering, however, to pull back again the instant this upward movement is arrested. Hence the great importance of fanning.

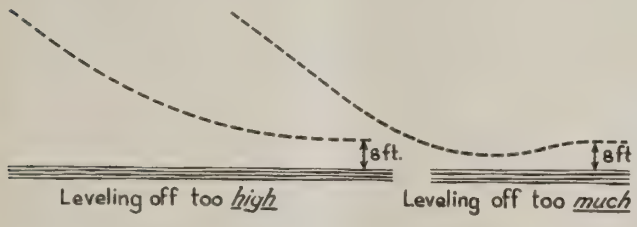

Figure 3

Figure 4

The phase which includes loss of speed in air has the faculty of trying the patience of the student, for he appears to dislike holding the machine level. He signalizes this as a rule by either a premature attempt to put it on the water, with a certain rebound at this great speed, or by heaving back in anticipation of the time to squash, which results in a veritable "zoom."

Many landings hitherto well executed, with the point of loss of flying speed at the proper height, are spoiled by failure to "squash" properly. As the machine settles the controls must be pulled back rapidly, often to the chest. Bear in mind, no matter how the glide, the approach, or the amount of fanning, always be sure when hitting the water that the controls are well back and that the tail of the pontoon is the point of contact. Failure to do this is the cause of more faulty landings than all other faults.

It is better to level off too high than too low. Some students confuse leveling off too high with too much, and therefore attempt to compensate by steepening the glide. This only augments either error, because the faster the glide, the quicker will the leveling off process occur, with greater resultant reascension. Others hope to correct these faults by not leveling off at all, and these are the despair of instructors.

Flexibility in controlling and a resolution to land on the tail, are the chief aids to a mastery of the art of landing. Likewise, the student must ever bear in mind that the psychological idea uppermost in landing is not to *put* machine on water, but rather to *permit* it to put itself on.

Recovery from a "bounce" is quite important. Where the rebound is hard, open throttle and proceed, particularly when it results from failure to level off. When a skip is slight, it is only necessary to withdraw controls a trifle. Rebounds occur on slow landings from failure to "squash" machine on the tail of pontoon. In such cases throw machine forward as it travels upward, and quickly pull controls back to chest as it settles. Generally it is not necessary to proceed with throttle from a bad stall landing, for the first contact in such cases is always the hardest.

Sometimes when the student is in doubt as to the real cause, it is permissible to give half throttle and hold controls back until the machine settles to water. This is called a power landing.

Hitherto, on this subject, I have spoken almost exclusively of longitudinal control. Now it is quite as important to maintain lateral stability as in flight. Landing on one wing, causing machine to swerve violently, places great strain on the structure.

Not the least important is the use of rudder in order to maintain landing directly into wind. Cross-wind landings result in side drift, usually incorrectly referred to as a skid. The wind will carry machine sideways, and such a landing places greater strain on the pontoon structure. To minimize this it is necessary to kick rudder into direction of drift; an attempt to overcome this drift by ruddering against it will only aggravate the fault. This is a very important feature of landing. Should a true skid occur, the same rule will apply.

Spirals

The fundamental principles which govern spirals are much the same as turns; in one case the motive power is derived from gravity, in the other, the engine. Many students forget this, consequently the failure to bank quite as much as on turns results in the common fault of skidding. This is particularly bad in a flat glide, as it invites a spin.

In executing a spiral, the rules of rudder and aileron action apply as on a turn. Care must be taken, inasmuch as gravity is the motive power, to glide straight until sufficient momentum is attained. Overanxiety to begin the turn is a common fault.

In shooting a mark, students are often so intent on reaching it as to disregard the necessity of momentum, with consequent spills. On the other hand, students often go to extremes to avoid a flat glide, as the spiral seems to confuse their judgment. Nosing down too much, while it is not dangerous, is nevertheless amateurish and inexpert. A pilot should not lose over one thousand feet in a complete turn, which is a safe margin for a beginner.

In spiraling into the wind for a landing, if the pilot finds that he cannot quite get around, it is preferable to land cross-wind, rather than take a chance of making a too sharp turn just above the water.

"Flipper" spirals will be considered in the remarks on inverted control.

Inverted Control

The theory of inverted control in air flight is the substitution of resistance to centrifugal force for that to gravity. In other words, an inverted control turn, commonly called "flipper" turn, is made so sharply that the reaction due to centrifugal force becomes more potent than that due to weight.

As may be presumed from this, the amount of bank is very great, varying from about forty degrees to almost vertical. It can easily be understood that, as this bank increases, the rudder position in relation to the horizontal moves from vertical to horizontal, while the elevators correspondingly move from horizontal. Now when the bank is great enough to imply inverted control, this change has progressed to the extent that the rudder is more or less horizontal, the elevators vertical. Thus, in relation to gravity, the rudder has become the elevator, and the elevator the rudder; hence the name "inverted control."

The practical way to accomplish an inverted turn varies. The usual method is to begin a customary turn until a forty-degree bank is attained. As the degree becomes greater than this, the yoke is gently pulled back so that when the bank is practically vertical, the controls may be back to the chest. The farther back the controls, the sharper is the turn. The extent of withdrawal is so regulated that the nose of the machine remains just above the horizon. If there is any tending to stall in so doing, this simply signifies that the machine is not banked enough for that degree of elevator withdrawal.

The rudder position does not change, becoming a slight "down rudder" in the inverted position. Some experienced pilots do not use rudder at all in turning, but simply bank to the proper degree and then pull back correspondingly on the elevators. Some indeed, carry this to extremes, actually applying reverse rudder, which then becomes "up rudder" by the inversion; the bank in such cases must be very steep, and the withdrawal of the yoke, sharp. This is a rare practice in seaplanes, but it is cited for the benefit of those who believe it is necessary to rudder hard in order to make a sharp turn. Too much down rudder will precipitate a spin, particularly to the left. With excessive "up rudder," it is first necessary to stall and side-slip. The greater the bank the lesser the rudder used.

To complete an inverted turn, invert the order of beginning it by returning elevator to neutral, aileroning against bank and finally, neutralizing all surfaces.

The principles which govern "flipper" spirals are substantially the same as in turns, as before, differing only in the substitution of gravity for engine as the motive power. Speed must first be attained, and the descent regulated by the rudder (which has become the elevators). Too much "down rudder" will lead to a spin. On the other hand, with sufficient bank, and controls back, many seaplanes, such as R's, will take full "up rudder" without either spinning or stalling. A partial side-slip will result, with sufficient forward momentum to maintain the reaction to centrifugal force against the arc of the turn.

A skillfully executed "flipper" spiral is one of the prettiest and most difficult evolutions in flying; more so than many so-called "stunts."

(To be concluded)

NAVAL and MILITARY AERONAUTICS

Britain Pays Air Service $27,000,000

Washington, D. C.—According to a letter made public by the War Department, an agreement between the British Government and the War Department has been reached and a check for $35,176,-123.10 has been drawn to the credit of the United States; $26,947,069.10 of this amount is for the account of the Director of the Air Service for the following:

Liberty motors.....	$13,672,518.90
Aeroplane spruce..	13,274,554.20
	$26,947,069.10

This settlement is unique in many ways, including the large amount involved, the fact that most of the agreements entered into were verbal, and that no arbitrational committee was required to settle the matter. Chester W. Cuthell represented the War Department and Lord Moeforth, the Minister of Munitions for War, the British Government.

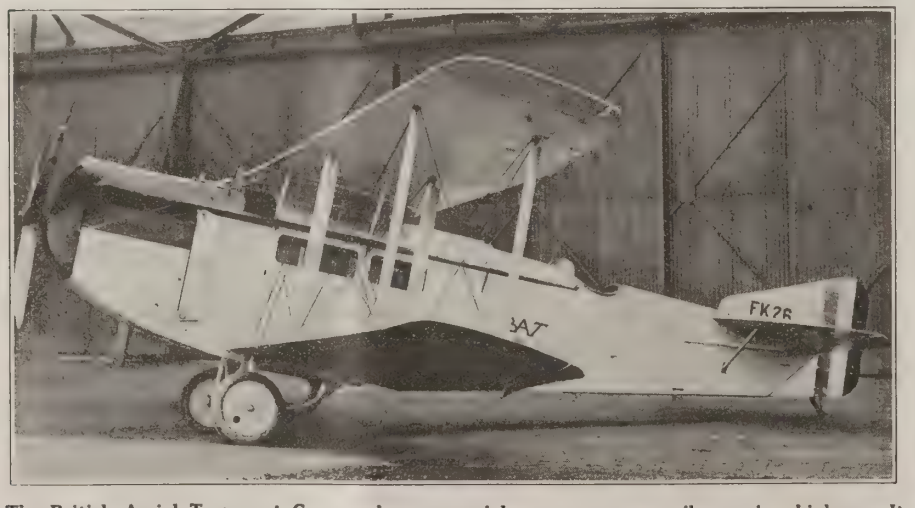
Air Service Authorized to Make Exhibition Flights

Washington, D. C.—According to an announcement of August 7, issued by the War Department News Bureau, the Director of Air Service is being authorized to grant requests for aeroplanes for exhibition flights whenever consistent with necessary activities of the Air Service, condition of material and the number and degree of training of the Air Service personnel provided all expenses incident to such flights are assumed by the local authorities.

All-American Pathfinders to Make Transcontinental Recruiting Flight

"The All-American Pathfinders," a complete squadron of thirteen Curtiss army biplanes, fully equipped, will start on a transcontinental flight from Mineola to San Francisco August 13. The planes will be under command of Major Ora M. Baldinger, and will fly in squadron formation throughout. The itinerary of the flight embraces fifteen states and covers 4,183 miles. Stops and exhibitions will be made at 171 cities.

This nation-wide flight is to be a campaign of education for the people of the country, as well as a recruiting campaign for all branches of the army. It will show the public the actual working of an air squadron operating away from a fixed base for the first time in the history of the country. The detachment will consist of twenty-two commissioned officers and eighty enlisted men, all specially chosen for their particular technical branch of the service.



The squadron has been divided into seven sections, each performing a distinct function. The first is the headquarters and advance section, which will be the executive head for the unit, and also arrange for all base stops prior to its actual arrival.

The aerial routes, mapping and landing field section will compile and record all important aerial information. The recruiting section will examine and accept recruits for all branches of the army. The flying and field operations section will direct all flights. The other sections are radio, photographic and balloon and airship.

The radio section is equipped with the latest type of apparatus. Radio telephones will be used on all the machines, and will be operated over all important cities. Semi-daily reports of the progress of the squadron will be made to the War Department in Washington by wireless.

The balloon and airship section carries six specially constructed balloons known as the propaganda type. These will be flown at all base stops. In addition a full-size type "K" observation balloon will be inflated at each stop, so the public can examine the type of lighter-than-air craft used in the war. An accurate working model of the latest type of dirigible operated by electric power also will be exhibited.

In addition to these a special searchlight and field lighting section from the engineer corps has been attached to the squadron. This section carries a complete searchlight unit of the 60-inch anti-aircraft dishpan type. This light has a power of 250,000,000 candles, and its beams can be seen by an aeroplane from a distance of 110 miles. This section has also a complete field lighting set for illuminating an aeroplane landing field at night.

The British Aerial Transport Company's commercial, passenger or mail carrying biplane. It has a useful load of 1000 pounds, and is equipped with a Rolls-Royce Eagle VIII

Rank and Strength of Officers Reserve Corps

Washington, D. C.—A statement has been issued by the Statistics branch of the General Staff, giving the number and range of officers requesting regular army commissions in all branches of the services up to July 18, and the number and rank commissioned in the Officers' Reserve Corps up to July 31.

Rank	Requested Com. in Air Serv., Reg. Army.	Com'd in Officers' Res. Corps, Avia. (Flying).	Com'd in Officers' Res. Corps, Avia. (Non-flying).
Lieut. Col.....	3	0	0
Major	36	22	99
Captain	209	96	301
First Lieut....	561	446	621
Second Lieut..	1,529	4,025	1,818
Totals	2,338	4,589	2,839

In addition 15 have been commissioned as second lieutenants, balloon section, Officers' Reserve Corps, up to July 31.

270 Planes for Panama Canal Patrol

Washington, D. C.—It is stated that 270 planes have been shipped to the Panama Canal zone for patrol duty.

648 Air Service Contracts Yet to Be Liquidated

Washington, D. C.—The Statistics Branch of the General Staff announces that 648 contracts for the Air Service remain to be liquidated. The average value of all contracts liquidated or to be liquidated is $351,000 and the average value of those remaining to be liquidated is $297,000.

The value of the uncompleted portions of suspended War Department contracts that had been liquidated to July 19 totals $1,715,605,000, or 46.1 per cent of the total value of suspensions as reported to that date.

All Long Island Flying Fields to Be Abandoned

New York, N. Y.—According to statements appearing in the press, it is said that orders have been issued for the abandonment of all army flying fields on the Hempstead Plains of Long Island, which include Hazelhurst, Mitchel, Roosevelt and Brindley Fields. Col. Archie Miller, in command of all flying activities on Long Island, when questioned denied any knowledge of the alleged order. The rumor states that the 1,000 or more enlisted men stationed at the field have been ordered to aviation fields in Florida and Texas. The 500 or more serviceable planes at these points are to be kept in hangars under guard of four or five men in charge of a sergeant.

Montauk Naval Air Station Abandoned

Montauk Point, Long Island.—The Montauk Naval Air Station, which was built here at an expense of several million dollars, was closed officially at 5:02 P. M. on August 4, when the flag lowering ceremony took place for the last time, and its building and machinery soon will be scrapped.

Abandonment of the station had not been expected so soon, and until recently mechanics had been at work there to complete the dirigible C-6, sister to the C-5. The C-6, which was almost ready to fly, is to be disassembled and shipped to Santiago.

60 Per Cent. of Air Service Contracts Liquidated

Washington, D. C.—According to a statement prepared by the Statistics Branch of the General Staff on August 6, $288,170,000 of the $480,598,000 of Air Service contracts outstanding at the end of the war have been liquidated. This represents 60 per cent of the entire amount.

To secure the liquidation of these contracts payments totalling $64,511,000 were required, or 22 per cent of the total liquidation. Thus a saving of 78 per cent has been made.

36,000 Miles of Army Cross Country Flights in Week

Washington, D. C.—The mileage flown by Army aeroplanes in cross-country flights for the week ending August 2 was 36,399. This figure does not include the mileage devoted to the instruction of enlisted men, of whom twenty-nine have already qualified as pilots.

First Enlisted Man Pilots an Aeroplane Over the Sierras

Reno, Nev.—Sergeant T. J. Buckley, in Curtiss JN6-H, made a flight from Sacramento to Calneva, 195 miles, in 108 minutes; Calneva to Reno, 65 miles, in 48 minutes, at an altitude of 14,000 feet. He is the first enlisted man to fly over the Sierra Nevadas.

Problems in Wood Propeller Design

(*Continued from page* 1054)

as metal, these materials are being used very satisfactorily in ordinary work. In applying fabric coverings, that portion of the blade tip which is to be covered is first tooth scraped parallel with the grain to form a good surface to which the glue will adhere. Then the surface is coated with a glue sizing material, the dampened fabric being also given a glue sizing coat at the same time. Then, beginning at the leading edge, the non-working face of the blade is covered with the fabric, all irregularities or ridges being worked out by the fingers until a good, smooth surface is obtained, the fingers being moved from the leading edge to the trailing edge.

Then by using a small rounded stick, all air pockets and excess glue is worked out, starting at the center and working toward the edges. Next the fabric is ironed down carefully with a hot iron to absolutely insure uniform adhesion of the cloth all around, and to eliminate any trace of puckering, formation of air pockets, etc. With the trailing edge covered, the fabric is trimmed flush with the leading edge, and when the blade is turned over for the application of the fabric to this side in the same manner, an overlap on the non-working face at the leading edge is made. This should be about ½ inch wide.

This tipping process is done before any of the finishing varnish or filler is applied to the propeller, and with the fabric in place, the next thing is to proceed with the application of the filler to the non-tipped portion, after which the fabric is given two coats of aeroplane dope, twenty minutes to an hour being allowed between the application of the two coats. A light sanding of the doped fabric comes next, when the entire propeller is ready for its final finishing with spar varnish.

As already brought out, the fabric tip is not advisable for other than land machines. Such ships are rarely exposed in regular service to such severe conditions but what the linen covering will afford sufficient protection to make their use advisable when the great simplicity of putting on such tips is taken into consideration. Besides affording good protection against abrasion of the leading edges, such tips act as a sort of binding that in most cases holds the fibers of the wood together at high speeds. In this they have a great advantage over metal, for being very light and there being no holes in the wood, the centrifugal forces and splitting action of metal sheathing is overcome.

Fabric tips are not much protection against water spray, as tests and service have shown. It soon wears the fabric completely off the leading edge, although not disturbing that part of it on the faces themselves. But for ordinary mist, flying particles, pebbles, etc., it is safe to say that the fabric tip affords enough protection to warrant its use in preference to other tips, all things considered.

Pig Skin Covering

This method of tipping, as might be expected, is the next thing to metal when it comes to protection against long grass, sand, gravel, wet grass, and the like. It will take care of the propeller blades even when subjected to water spray, where the water is not of too long a duration, and in many instances has proved very satisfactory where a plane had to be out in rain.

There is no doubt that properly applied pig skin, with its known wearing qualities, acts as a strengthening agent for the wood, preventing the fibres from pulling apart when the stick is subjected to high speed. In fact, in many tests pig skin-tipped blades have withstood high rotative speeds for long periods without showing any sign of failure. This material is, however, harder to apply than fabric, and for general all-around conditions it is a question whether or not it possesses enough advantages over linen or cotton to warrant its use in preference. Planes that have to do a great deal of night flying or those operating in wet or damp regions, though, would best have propellers with tips of this material in preference to fabric, for reasons above brought out.

Other Methods of Tipping

Various other schemes and materials have been put forth for propeller tipping, but none of these have as yet shown results that are the equal of fabric or pig skin when all advantages and disadvantages have been weighed. For instance, celluloid, hard rubber, zinc and aluminum spraying and composition coating have been tried with varying degrees of success.

Celluloid coverings might at first thought seem very advantageous, but in tests it was found that this material, due to its shiny texture, gives off a reflection that is very objectionable to the pilot. The sun's rays cause it to make a glare that is dangerous in its blinding action upon the occupants of the plane. Being a brittle material also, it is easily cracked unless of a goodly thickness, which means weight.

Hard rubber deposited over the surface has not matched up to expectations of those who thought this would be the solution of the problem. Of course, from the strength standpoint, rubber would not be considered, but it was primarily intended as protection against stones, pebbles, etc., as well as being impervious to moisture. But it chipped very easily in tests, and has been discarded.

Sprayed metal would seem to have possibilities, although very little development work has been done along this line. It has shown itself, in what tests have been made, to be very good protection against flying particles and rain drops and spray, as well as tall and wet grass. However, as it is much harder to apply than most other coatings, some simpler methods than now used would have to be worked out before it could be considered practical, and it is a question whether the effort is justified.

A view of Parkwater—the excellent 500 acre Aviation Field at Spokane, Wash.

FOREIGN NEWS

Non-Stop Flight from Madrid to Rome

Rome.—Aviator Stoppani, piloting an aeroplane from Madrid to Rome, arrived on August 6 at 5:45 P.M. He left Madrid at 6 A.M. of the same day.

The flight was made without stop, by way of the Gulf of Lyons, Marseilles, Spezia and Pisa.

The aviator carried a letter from King Alfonso of Spain to King Victor Emmanuel of Italy.

First Flight Over Canadian Rockies

Lethbridge, Alberta.—Captain E. C. Hoy made the first flight over the Canadian Rockies in a flight from Vancouver, B. C., lasting over 14 hours. He took off at 4:15 A.M. and arrived at Lethbridge, about 500 miles distant, at 6:22 P.M.

Aircraft to Compete with Cables

Mr. G. Holt Thomas, organizer of the Aircraft Manufacturing Co., in a paper before the London Society, read an instructive paper on "London and Its Future Aerial Transport." Mr. Thomas outlined the importance of London as an air traffic center. Regarding the London-Paris aerial traffic, he said that it cost 2d. per word to send a telegram from London to Paris. Assuming that it cost £120 to fly from London to Paris, and taking one of his own machines, which was to-day used on the military service between London and Paris, they could carry (he was quoting General Sykes) 672 lbs. of matter. Assuming such a low weight as 2,000 words per ounce—he thought it could safely be put at 5,000—the number of words carried would be 21,500,000, which worked out at so low a figure that one could hardly talk about the price per word. As the calculation would show, they could carry words at 700 a penny.

The same calculation showed one—and this was a subject which they had been specially studying—how the telegraphic and telephonic communication of this country could be linked up with the telegraphic and telephonic services of another country. There was another reason for talking chiefly of mail and matter, as compared with passengers—viz., the expense. Suppose it cost 10s. a mile, or £120, to fly to Paris, carrying two passengers. The price of £60 was almost prohibitive. But consider the weight, say, of two 11 stone passengers as made up of half-ounce letters, and the situation was completely changed. The two 11 stone passengers equalled 9,856 letters, and at the same price per trip, the transport of the letters cost about 3d. each. The charge would, of course, have to be much higher because one would not get 10,000 letters to deliver. Also a special form of collection and delivery would have to be arranged for, as it was no use flying from London to Paris in two hours and taking four more to deliver letters to their destination.

King George, Chief of Royal Air Force

London, Aug. 1.—King George has assumed the title of chief of the Royal Air Force. New titles for the commissioned ranks in the air force have been given by King George, namely, Marshall of the Air, corresponding with a Field Marshal; Air Chief Marshal, corresponding with General; Air Marshal, corresponding with Lieutenant-General; Air Vice-Marshal, corresponding with Major-General, and Air Colonel-Commander, corresponding with Brigadier-General.

The idea in giving the ranks is to preserve the independence and integrity of the air force as a separate service. The titles will come into operation immediately.

Berlin-Munich Airship Service

Berlin.—Zeppelin airship service between Berlin and Munich will be inaugurated in the near future, says the Vossische Zeitung. Flights will be made regardless of weather conditions, and it is expected that the journey will be covered in seven hours. The fare will be 300 marks (normally $753.

Brazilian Government to Finance Transatlantic Flight Preparations

Rio Janeiro.—A prize of $1,500 for the first Brazilian or Portuguese military aviators to fly between Lisbon and Rio Janeiro is proposed in a resolution introduced in the Chamber of Deputies. The measure calls for the Government to finance preparations for the flights up to an amount not exceeding $150,000. It is provided that the flight shall not require more than 168 hours.

The Portuguese Government on June 6 offered a prize of 30 contos (approximately $32,400) for the first Portuguese or Brazilian aviator to fly from Portugal to Brazil.

R-80 to Start Passenger Service Between London and Brazil Soon

London.—*The Daily Graphic* says that the first passenger airship is due to sail from Barrow-in-Furness to Rio de Janeiro some time during August. Twenty passengers and a small cargo will be carried aboard the vessel, which will be fitted out with all the luxury and comfort of an ocean liner.

The airship will fly by way of Lisbon, Sierra Leone, and thence to Rio. The anticipated flight will take about four days each way, and if successful will be the prelude to a regular service, which will be maintained by Vickers.

Sir Woodman Burbidge has booked three berths for himself, his wife, and a friend for the round journey to Rio and back. The price of the tickets was £1,000 apiece.

The R-80, as the airship is now known, has been under construction at the Vickers Barrow works for some months. She was commissioned by the Admirality last year, with the object of producing a rigid British airship of medium dimension which would give the same performance as the latest German Zeppelin.

She has a capacity of 1,250,000 cubic feet, or rather more than half the size of the R-34. She has a cruising speed of forty-six miles and a full-power speed of sixty miles an hour, and is 535 feet in length.

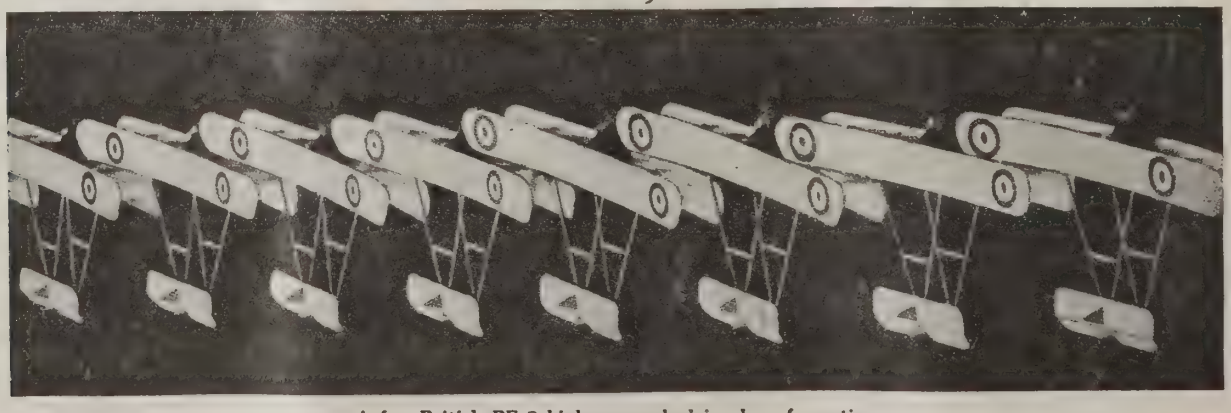
The passengers' living quarters are on the top of the hull, where are situated a large saloon fitted out like a Pullman car, a roof garden, and a shelter deck, and cabins of sleeping berths.

Five Motored German Aeroplane Falls Carrying Gold to Ukraine

Berlin.—A special despatch to the *Lokalanzeiger* from Rybnik, upper Silesia, says a large German aeroplane belonging to a German airship works fell on August 4 during a flight, killing seven of its occupants, including the pilot, Bindereif.

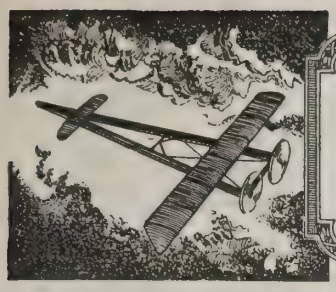
The accident occurred near Ratibor. The aeroplane carried 3,000,000 rubles in Ukrainian money and a sack of Russian money. The despatch says it is probable that former Finance Minister Witousky of the West Ukraine Republic, who attended the Peace Conference and later visited Berlin for a few days, was a passenger.

Bolivia Employs American Officers to Build Up Air Service



Captain Donald Hudson, formerly a member of the first pursuit group of the American Expeditionary Forces in France, has been employed by Bolivia to organize and instruct a flying corps in its army. It is said that Bolivia had decided to secure instruction for its army by discharged American officers after it had failed to secure admission of picked cadets to the West Point Military Academy. The American Government is unable to accept more foreign students at the American school.

Aviator Makes Non-Stop Flight From Santiago to Buenos Ayres



Buenos Ayres, Argentina.—In making his non-stop aeroplane flight from Santiago, Chile, to this city on August 5 in 7 hours and 10 minutes. Lieutenant Locatelli, the Italian aviator, averaged approximately sixty miles an hour. His greatest altitude was about 17,500 feet.

British Aircraft Maker Reached Quantity Production in Quick Time

London.—The record of Ruston, Proctor & Co., Ltd., of Lincoln, in reaching quantity production despite war labor conditions and the necessity of constructing factories and training unskilled workers is an enviable one. Ruston's signed their first contract with the War-office for the supply of aeroplanes on January 15th, 1915. Before the work could be undertaken a factory had to be built. For this purpose three bays of shedding formerly used for the storage of thrashing machines were taken over and on the adjoining ground—originally a marsh, if we remember aright—further accommodation was erected. The workpeople—many of them girls—had to be trained, but in spite of all difficulties the first aeroplane was completed and accepted by July 15th, 1915, exactly six months from the signing of the contract. Soon afterwards the firm was producing an average of seven or eight complete aeroplanes a week and engaged on aero engine work as well. The thousandths aeroplane—a Sopwith camel, it is stated—was turned out on January 4th, 1918. According to an announcement recently made, Ruston and Hornsby, Limited, as the firm has now become, will, when its war contracts for aircraft have been completed, have delivered 2,725 complete aeroplanes and 3,200 complete aero engines, together with the spare parts for 800 other engines. The first aeroplane built by the firm was of the B.E. 2 d type and the fourth is said to be the one used by Lieut. W. L. Robinson in destroying the Ruffley Zeppelin on September 3, 1916.

ELEMENTARY AERONAUTICS and MODEL NOTES

By John F. McMahon

THE ILLINOIS MODEL AERO CLUB HAS MADE A CLEAN-UP IN THE CONTESTS FOR THE AERIAL AGE AND VILLARD PRIZES

THE Illinois Model Aero Club has made a clean-up in the model contests for the AERIAL AGE prizes, as well as winning the Henry S. Villard Trophy for the third and final time.

Although many clubs throughout the United States competed for the rich prizes offered, none made the showing that this club did. Their records are something to be justly proud of and each member of this studious and growing club should be congratulated.

The Aero Science Club of America and the Pacific Coast Model Aero Club were completely outclassed by their friends in Chicago and their only soothing salve is the fact that they will have a chance to turn the tables at a later date.

The results of the Illinois Club's contest are really wonderful in view of the fact that most of the older members are advanced above the model stage and are devoting their time to the large machines. This leaves the field open to the latest members, who have shown that they have the makings of real champions in model aeroplane flying.

You would think that they would be satisfied to win the beautiful Villard trophy and call it a day's work. No, not these young conquering heroes; they believe that anything half done is not done at all, so they went out to win all or none, and they sure have done their work well.

This should not deter the other model flyers throughout the United States; in fact, it should be an inspiration, as it is just as easy for you to be successful in the game if you devote your time and energies to the intricate construction and design of a successful long-distance racing model. Many designs of racing models have been shown on this page and any of them are capable of travelling 2,000 feet or over with a little practice.

The secret in long-distance racing is to have a light model with large wing surface, large diameter propellers and just enough rubber to turn the propellers about 800 r.p.m. These models float more than they fly and very little propelling force is needed to push the model through the air. In the near future we will again illustrate and describe a long-distance flying model.

The Henry S. Villard Cup which is now the property of the Illinois Model Aero Club

The winners of the Rising from the Ground Contest for the AERIAL AGE prizes, namely, the Gold, Silver and Bronze medals, which were shown on this page some time ago, are as follows. (Winners, distance, club and prize):

Schweitzer, 1,805 feet, I.M.A.C., gold medal.
Lucas, 1,447 feet, I.M.A.C., silver medal.
Jaros, 1,273 feet, I.M.A.C., bronze medal.

The Long Distance Model Contest winners are as follows:

Schweitzer, 2,778 feet, I.M.A.C., gold medal.
Pease, 2,410 feet, I.M.A.C., silver medal.
Jaros, 2,108 feet, I.M.A.C., bronze medal.

The Villard Cup was won by the following team. (Name, total and average):

Schweitzer .....5,369 feet
1,789 2/3 feet
Cook, 5,240 feet, 1,746 2/3 feet.
Jaros, 5,023 feet, 1,674 1/3 feet.
Pease, 4,959 feet, 1,653 feet.
Lucas, 3,739 feet, 1,246 1/3 feet.

The beautiful AERIAL AGE Cup for the best constructed scale model of the flying or non-flying type was won by Henry Smalline, of 227 Lewis Avenue, Brooklyn, N. Y. His model was an exact copy of the little Berkmans scout and is indeed worthy of this beautiful prize.

More contests are to be held in the near future, and I would advise the readers who do not get AERIAL AGE regularly, or who have to depend on some newsdealer supplying them, to subscribe for the paper, if only for six months. Special offers regarding subscriptions can be had by applying to the Subscription Department.

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Everything is Going Up

The American Eagle

Blue spreads the sky above me
Gently blows the western wind,
I trundle the little "pursuit" out
And closely tuck me in.

The "Liberty" hums a merry tune
Seeming eager to be off,
I gently wave the "mechs" aside,
And swiftly soar aloft.

Below me spreads the countryside
With camp and village, hill and mead,
I note the river's silvery thread,
And softly guide by flying steed.

This is the life for bird and man,
My soul exultant is and glad,
While, unbidden, memory conjures up,
The magic carpet of Bagdad.

Swiftly above the clouds we rise,
My willing steed and I
And on the sheeny, fleecy things
We look down from on high.

Again we view the landscape o'er,
'Tis Mother Nature's lap,
And wrest the very secrets from
That ever changing map.

The trench, the gun or tortuous road,
The wood or farmhouse grey,
I fix their menace or harmlessness,
Then quickly speed away.

I sit and dream of fairy tales
Of Pegasus' wonderful horse,
Of twenty-league boots or flying chests
And they're a matter of course.

I travel far on wings of winds
I see all the wondrous sights
That gladdens the American Eagle's eye
Or dwell in Arabian Nights.

Oftimes the bursting shrapnel shells
Like pursuing Trolls come after
But soon we maneuver out of reach
Or pass them by with laughter.

Sometimes we meet the dragon foe
And by vrille or baffling loop
We elude his deadly fiery breath
And swiftly on his tail we swoop.

Then when the day is ended
And the golden red is dyeing he west
We gladly circle homeward

in conference appears an extraordinary similarity in condition and in conclusions drawn from the experiences of the five difficult years of mistake and achievement in the prosecution of the war. Perhaps no stronger or more simple presentation of the regard in which the future of aviation is held in allied countries can be given than by quotation from two letters of M. Clemenceau, copies of which were obtained in France. The first is addressed to the President of the United States, urging upon him the immediate consideration of matters aeronautical and in connection with the Peace Conference. The second is addressed to the President of the Republic of France, submitting the draft of a decree creating a separate department of aeronautics placed transitorily under the Ministry of War—an intermediate step possible without legislation and looking to the early creation of an independent Ministry of the Air:

FEBRUARY 16, 1919.

The President of the Council, and
The President of the Interallied Peace Conference.
To the President of the Republic of the United States.
Interallied Aviation Committee:
Mr. President:

I have the honor to acknowledge the receipt of your answer of February 7 to my letter of January 24. I enclose herewith copies of the letters which I have received from Lord Milner and from Monsieur Orlando, as well as my replies.

I am pleased to note that you agree in principle with my proposition to create an aviation committee for after the war. I take the liberty of insisting o nthe necessity of creating this committee without delay, in order to be able to utilize it as an advisory organ for the Peace Conference. Indeed, the clauses for aerial protection seem to me to have at least an importance equal to the clauses for military and naval protection, and it is of the greatest interest to have a study made by competent personalities of the measures to take against the eventual constitution of a German military fleet. I cannot insist too strongly on the imperious necessity of this study, on account of the proximity of Germany to London, Brussels, Paris and Rome.

Likewise, I adhere entirely to the British proposition, which seems to be practical and effective, and I request you likewise to give it attention. In case it seems acceptable to you, I wish you would let me know if you could delegate two representatives to the next meeting of the new Interallied Committee, which will take place on Thursday, March 6, at ten o'clock, at the Directory of Aeronautics, 260 Boulevard St. Germain.

Please accept, Mr. President, the assurance of my highest consideration, etc.

(Signed) CLEMENCEAU.

REPORT TO THE PRESIDENT OF THE REPUBLIC.

PARIS, June 6, 1919.

Mr. President:

Aircraft has developed considerably during the war. It should at this time adapt itself to a no less important part in peace time. But because of the many initiatives which cooperate in its new use and development the efforts and means are dispersed in various ministerial departments.

The future of aviation in France will only be assured by the coordination of all efforts and the unification of the general services. Also, it will give the advantage of better work from the personnel and credits which are actually effected to similar objects in different ministries.

With this object in view, and according to the propositions of an interministerial conference which I am able to assemble, I have the honor to submit for your signature the following decree creating an organ of general coordination of aviation.

This should not be confused with any of the particular aviations of the various ministerial departments. At its origin it will be attached transitorily to the Ministry of War.

I am, sir, yours respectfully,

GORGES CLEMENCEAU,
President of the Council, War Ministry.

Even before the report of this Mission can be given consideration a step similar to that proposed by France will have been taken by Italy. Here, however, the Department of Aeronautics is being placed under the Ministry of Transportation —a makeshift arrangement frankly acknowledged transitory and immediately possible without the legislation needed to create the clearly foreseen ultimate—the Italian Ministry of Air.

England more than two years ago began the coordination

(*Continued from page* 1047)

accompanying drums and springs, are housed or concealed within the space between the fueslage frame and side sheathing (19) of the fuselage, which is spaced therefrom and curved to give the desired streamline contour. The bottom wall of the sheathing (9) is provided with a longitudinal slot or opening at each side of the fuselage frame, as indicated in dotted lines at A, A in Figure 1 to receive the members (2) and permit the members (10) to pass upwardly inside the sheathing when the chassis is folded or retracted, and likewise said bottom sheathing has a transverse opening and a diagonal opening covered by channel members forming recesses or chambers to receive the chassis frame members (3) and (6), respectively. A filler plate (20) or closure is provided for each opening in the sheathing and each plate is normally projected by springs (21) when the pocket is empty to afford a substantially flush continuation of the skin or sheathing (9) across the pocket mouth, the filler being pressed back into the recess as shown in Figure 4 when the chassis frame is drawn up as indicated in dotted lines in Figure 2. Furthermore the cross sectional shape of the members 2, 3 and 6, of the chassis frame, as clearly indicated in Figure 4, is such that the lower surface (22) thereof is substantially flat and likewise forms a substantially flush continuance of the surface (9) when the chassis is retracted, so that the wind resistance is thereby minimized. As a further detail of construction the exterior sheathing may be so positioned as to envelop the wheels when the device is retracted, while at the same time the lower rim of the wheel is in place where it can act as a support.

As a result of this construction, an alighting device is had that is completely concealed with the exception of the bearing wheels within the fuselage when the machine is in flight and that when extended offers minimum wind resistance because of the single bracing member and the cross sectional contour of the parts while the springs are positioned to minimize the stresses encountered by the device when the machine encounters the ground. All the weight of the machine is communicated almost directly to the wheel through the vertical struts without appreciable effect on the frame that the wheels are mounted on, so that the latter cannot tend to materially distort the frame and the same can therefore be made extremely light.

War Department Moves to Protect Its Inventions

Washington, D. C.—The War Department authorizes publication of the following information:

It has come to the attention of the Secretary of War that inventions relating to military affairs made by those in the military service of the United States and in the discharge of their official duties are not being patented by inventors, but by certain contractors, who embody these inventions in supplies to the Army after obtaining patent in their own names, and are collecting royalties for same.

The above action is illegal and has resulted in material loss to the Government. All heads of departments, chiefs of bureaus or other agencies of the War Department having to do with the making and enforcement of contracts, are directed to consider Act of July 1, 1918, which amends Act of June 25, 1910, which extends remedy afforded patentees by suit in Court of Claims for compensation for use of their inventions.

The heads of departments, bureaus, etc., are directed to take necessary steps to protect the Government by assisting employees to establish their rights to inventions, making full reports of the facts in each case.

The transfer of the Inventions Section from the War Plans Division to the Operations Division is completed by a general order soon to be published to the Service. Hereafter, communications, re, inventions, including suggestions, ideas or plans of operation submitted to the Government for inspection, test or sale, received from any source, including the public, and any office of the War Department, staff, corps, supply depot, or any headquarters of military establishment will be referred directly to "The Inventions Section," Operations Division, General Staff, Washington, D. C. All men belonging to the service who have ideas for improvements in any of the materials, are notified to submit descriptions freely.

It is also directed that hereafter all communications re, rights to inventions and patents originating in military service other than Staff Corps and Supply Bureaus, be forwarded to Patents Section, Purchase Branch, Office of the Director of Purchase, Storage and Traffic Division, General Staff, Washington, D. C., except communications re, inventions or devices submitted to the Government for inspection, etc., from a technical standpoint, received in the War Department, shall be referred to Inventions Section, Operations Division, General Staff, Washington, D. C., as heretofore.

AEROPLANE INSURANCE

Merchants Fire Assurance Corporation of New York

This company issues policies covering aircraft against the following risks:

1—FIRE AND TRANSPORTATION
2—COLLISION (Damage sustained to the plane itself)
3—PROPERTY DAMAGE (Damage to the property of others)

Additional coverage may be had against loss by wind storm, cyclone or tornado.

We will be glad to discuss problems concerning aeronautic insurance.

of her aircraft activities—an effort which has resulted in placing her well in the lead in practically every phase of aerial development, and which has resulted in bringing her months ago to the establishment of a Ministry of Air, co-equal with her Ministries of War and of the Navy. That the present Ministries both for War and for Air centered in the same individual has no significance other than that of momentary expediency.

The whole trend of events touching the art of aeronautics in its broad relation to world progress, the experience in all allied countries (including the United States) during the five years past, the frankly discussed future plans under present consideration in foreign quarters and the views everywhere encountered by us, leave your Mission impressed with these unescapable conclusions:

1. That Italy, France and England realize fully the importance of aircraft in the military-naval and civil-commercial aspects, and purpose to encourage the general development of the art through governmental aid to commercial industry.

2. That Great Britain has come to consider the dominance of the air as at least of equal importance with that of the seas, and in frankly and avowedly planning a definite policy of aerial development to that end.

3. That any future war will inevitably open with great aerial activity far in advance of contact either upon land or sea, and that victory cannot but incline to that belligerent able to first achieve and later maintain its supremacy in the air.

4. That for economic reasons no nation can hope in time of peace to maintain air forces adequate to its defensive need except through the creation of a great reserve in personnel, material and producing industry through the encouragement of civil aeronautics. Commercial aviation and transportation development must be made to carry the financial load.

5. That no sudden creation of aerial equipment to meet a national emergency already at hand is possible. It has been proven within the experience of every nation engaged in the war that two years or more of high pressure effort have been needed to achieve the quantity production of aircraft, aircraft engines, and accessory equipment. The training of personnel, including engineering, production, inspection, maintenance and operating forces—covering some fifty distinct trades and some seventy-five industries—has proved in itself a stupendous task when undertaken upon the basis of the war emergency alone.

6. That the rapid adaptation of aircraft to the commercial uses of peace is everywhere being studied and planned. Under the forced draft of war, this newest and fastest agency of transportation has been brought to a high state of development. It must now be redesigned to meet the progressive demands of a civilization at peace.

7. That because of its great speed and range of operation, oceans, states, and even countries, are being passed over with a greater facility than are townships and counties traversed by the motor car. The need for international agreements governing the construction, operation and safety of aerial apparatus of all kinds is immediately before us.

8. That for the first time in the world's history the stage is set for a close international cooperation in the development of a great art at the very threshold of its era of commercial utility. Great Britain, France, Italy and Japan not only invite but urge the United States to share in this work.

9. That just as we now have national, international and interstate regulations, laws and agreements covering rail and steamship travel, and the safety and navigation of the seas, so must we have similar regulations governing aircraft and the uses of aerial navigation throughout the world. The International Convention drawn by the International Committee sitting in Paris under the Peace Conference, gives the first long step in this direction.

10. That the need in each country for a single authoritative point of contract for the conduct of all international aviation affairs, legal, operational, technical and political, is imperative. Such agencies have already been set up in England, France and Italy. The United States has under the terms of the International Convention no option but to follow these leads.

11. That in England, France and Italy sentiment is undoubtedly in favor of the centralization of aircraft development under one authoritative head. Difference of opinion has been encountered only in the matter of Army and Navy personnel and in the question of the independent fighting force.

England holds the initiative and is building her Royal

(*Continued on page* 1068)

Flexibility and versatility, resulting from combined stability and strength, commend Boeing Seaplanes to professional pilots and to sportsmen of the air. Ability to stand up under the most gruelling tests and day-in, day-out service, the result of perfected materials and refined craftsmanship, assure safety to the most daring. The greatest spruce-producing country in the world, surrounding the place of Boeing manufacture, gives its best wood to Boeing aircraft. Boeing Seaplanes combine symmetric and assymetric stability to a degree never hitherto attained. May we address you a personal letter?

Air Force co-equal with the Army and Navy. France and Italy follow England's lead, but seem inclined to leave questions of operating personnel for the present to War and Navy Departments, and to debate the need of an independent fighting air service. In all cases, forces operating in conjunction with military and naval units function under the military or naval high commands.

12. That among the many considerations of early moment requiring governmental direction may be mentioned the following:

(a) Federal and International laws governing the use of air routes.
(b) Federal and International control of pilots' licenses; examinations and tests required.
(c) Federal inspection of all commercial aircraft for airworthiness, or suitability for service.
(d) Customs and other regulations for cross State and National boundaries.
(e) International standards for methods of communication and signaling.
(f) International standards covering the marking or charting of air routes and of landing places for both day and night use.
(g) International specifications and rules governing the construction, equipment and operation of standard aerodromes, landing stations, signal towers and other aids to aerial navigation.
(h) Port regulations and fees covering seaplantes.
(i) Federal taxation of aircraft and license for its use.
(j) Safety measures and devices; legislation forcing adoption.
(k) Fire underwriter standards, regulations and safeguards; insurance of machines, of material and of persons in transit (property and life).
(l) The legal status of privately owned aircraft; the property rights of the air; liability for damage inflicted and incurred.
(m) International standards and specifications covering accepted practice in quality of materials, in factors of safety, and in methods of construction; an engineering literature of this new art must be created by International approval.
(n) Maps and navigation charts of the United States and its territories.

13. That we of today are conceivably no more qualified to judge as to the scale and development of the aircraft of ten years hence than were we of even five years ago able to foretell the achievements of today. We must bear in mind always that for every one mind focused upon things aeronautical in this earlier period, some thousands of keen minds are now versed in the aircraft art. With proper governmental encouragement, rapid progress seems inevitable.

14. That the broadest consideration for the ultimate welfare of American aviation must be given in the constitution of any organization set up for the co-ordination and control of aeronautics within the United States. The prerogatives and ambitions of governmental departments and of individuals must be assayed at true value.

15. That past experience and every economic consideration point to the vital need for the formation by the United States of a definite, comprehensive and continuing policy for the development of every phase of the aircraft art. Our Government is now faced with the task of nursing and actively encouraging a new transportation industry, whose healthy growth is vital to the future progress and defense of the nation.

Because of the lack of a definite, intelligent and sympathetic policy in our governmetal aircraft organization since the armistice, our American aeronautical industry, built up at such great expense of money and of effort, is rapidly disappearing. No sensible business man is justified in keeping money invested in the aircraft industry under the conditions which have maintained in the United States since November 11.

16. That the closest possible relations must continually exist between the aircraft agency of the Government and the production and commercial industry engaged in aircraft development.

17. That the industries involved in the production and commercial use of aircraft must be given recognition and representation in connection with all national and international activities bearing upon the direction and control of aeronautics.

TRANSCONTINENTAL AERIAL DERBY BEING ORGANIZED BY AERIAL LEAGUE

OVER $100,000 IN PRIZES

PLANS for a Transcontinental Aerial Derby, from New York to San Francisco, with over $100,000 in prizes, with a first prize of $20,000, have been announced by Captain Charles J. Glidden, the Chairman of the Aerial Touring Committee of the Aerial League of America, and donor of the Glidden Aeroplane Efficiency Trophy.

The Transcontinental Aerial Derby will be held under the auspices of the Aerial League of America and will be sanctioned by the Aero Club of America under the rules of the International Aeronautic Federation, which govern all aerial sporting events.

The Derby will be international in character and will afford a supreme test to the aeroplanes and motors entered.

So as to test the efficiency of different types of aeroplanes for touring and everyday transportation, and create maximum public interest in the contest, the race may be in legs of 250 miles each, with a compulsory stop at the end of each leg.

If this rule is adopted there may also be offered a $20,000 prize for a non-stop return race to be confined to the aeroplanes which can be proven theoretically to be capable of carrying the amount of gasoline required to cross the continent without stop, with 500 pounds of mail.

This is to be decided by a committee of aeronautic experts who will consider the matter from a practical standpoint. This committee will also define the handicaps to be placed on different classes of planes.

It has been proposed that the results in this contest be figured by the point system, allowing points for the records made by each aviator for each leg of the race. This will give equal chances throughout the contest to all the aviators.

The United States Army, Navy and Aerial Mail aviators will be invited to participate in the Derby. Captain Glidden will go to Washington to interview Army, Navy and Postal authorities, and extend them the invitations to participate.

The date of the Derby will be announced after conferring with the Washington authorities, aircraft manufacturers and owners of aeroplanes.

A committee is to be appointed by Rear Admiral Robert E. Peary, the President of the Aerial League of America, to have charge of the work of establishing landing places at intervals of fifty miles across the continent, along the Woodrow Wilson Airway.

FUTURE OF AERIAL TRANSPORTATION IS TREMENDOUS, SAYS FRENCH AUTHORITY

FIGURES regarding the tremendous interest existing in civilian aviation all over the world were given by Monsier Maurice de Saint Blancard, the Secretary of the Aero Club of France, and one of the highest aeronautic authorities, who arrived on "La France" and is the guest of the Aero Club of America at the clubhouse, No. 297 Madison Avenue.

M. de Saint Blancard stated that European countries are planning extensive aerial mail lines, and that France, England, Italy, Belgium and Spain are planning to establish aerial mail and aerial transportation lines to their African colonies.

"Successful flights have been made," said M. de Saint Blancard, "from France to Africa, from Italy to Africa, from England to Africa and to India, and have demonstrated the practicability of establishing aerial lines which will be economically practical besides cutting down the time of transporting mail and express to one-quarter of the time required by land and water transportation. Practically all the French, British and Italian manufacturers have produced aeroplanes fitted with cabins which permit air travel with comfort."

There is going to be, also, the employment of large dirigibles for aerial transportation on an extensive scale.

Over one million dollars has been offered in different countries for prizes and other aeronautic purposes, as follows:

(1) The British Government is offering prizes amounting to $320,000 for aeroplane competitions to develop safer aeroplanes.

(2) The sum of $400,000 has been given to the Aero Club of France by Henry Deutsch de la Meurthe.

(3) Prizes amounting to over $100,000 are to be offered for the transcontinental competition being organized by the Aerial League of America.

(4) The French newspaper, "Echo de Paris," has given $60,000 for prizes for a 2,500-mile circuit race.

(5) The French newspaper, "L'Avenie," has given $20,000 for cross-country contests.

(6) $50,000 has been offered in prizes to the first Australian pilot who flies from Great Britain to Australia.

(7) The London "Daily Express" has offered $50,000 for aeroplane demonstrations establishing aerial communications on a commercial basis with India and South Africa, the machines entered being required to carry at least one ton of cargo.

(8) A prize of $32,000 has been offered for the first Portuguese or Brazilian aviator who flies from Portugal to Brazil.

(9) A $50,000 prize has been offered by Thomas H. Ince for a trans-Pacific flight.

(10) A $25,000 prize has been offered by Raymond Orteig for the first flight from New York to Paris.

(11) A $2,000 trophy has been offered by Captain Charles J. Glidden for the Glidden Aeroplane Efficiency Tours, to be completed for under rules similar to the Glidden Automobile Tours, which did so much to bring about the use of automobiles for pleasure and transportation.

(12) A $5,000 prize and other prizes have been offered for the international marine flying trophy race, for the best speed over a distance of 200 miles, to be held in England in September.

M. de Saint Blancard stated that a number of long-distance aeroplane and dirigible flights were being planned in Europe, including a flight of 20,000 miles by the famous Italian poet, Gabrielle d'Annunzio, who plans to fly from Rome to Tokio and back.

All the above mentioned contests are to be held under the rules of the International Aeronautic Federation and to be open to all pilots holding the Pilot's Certificate of the Federation, which is issued in the United States by the Aero Club of America, 297 Madison Avenue, New York City, New York.

M. de Saint Blancard states that the Aero Club of France, which holds the International Aviation Trophy, which was won at the Chicago race by Jules Vedrine in 1912, was anxious to hold a competition this year, but found it impossible to organize this competition owing to the fact that no competitions could be held in France prior to the signing of the Peace Treaty.

SANTOS-DUMONT TO HEAD PAN-AMERICAN AERONAUTIC DEVELOPMENT

SEES VAST POSSIBILITIES IN LATIN-AMERICAN REPUBLICS FOR AMERICAN AIRCRAFT CONSTRUCTORS

ALBERTO SANTOS-DUMONT, the famous Brazilian inventor and aeronaut, who built and piloted ten dirigibles and several aeroplanes from 1898 to 1910, has arrived in the United States and is the guest of the Aero Club of America.

Mr. Santos-Dumont returned to the United States from South and Central America, where he has been travelling as Chairman of the Committee on Pan-American Aeronautics of the Aero Club of America, studying the possibilities of aerial transportation.

Mr. Santos-Dumont's report is not yet available, but it is understood he found South and Central America ready for extensive aeronautic development and that everyone of the Latin-American republics are anxiously awaiting the establishment of aerial lines to solve difficult problems of transportation.

It will be recalled that Mr. Santos-Dumont came to the United States from France in 1915, at the request of the Aero Club of America for the special purpose of heading a committee entrusted with the possibilities of establishing aerial transportation in South and Central America.

After studying the aeronautic situation and the possibilities of building larger aeroplanes for nearly a year, he started on his mission, which took him to the different Latin-American Republics. He attended the Pan-American Aeronautic Congress at Santiago, Chile, in March, 1916, where the Pan-American Aeronautic Federation was formed, and where he was made Honorary President. From there he travelled through different countries studying the subject, and when the United States entered the war, and Brazil declared war against Germany, he went to his native country, where he was placed in charge of important aeronautic work in developing the Brazilian Army and Navy Air Services.

The Committee on Pan-American Aeronautics of the Aero Club of America includes Alberto Santos-Dumont, Chairman; Henry Woodhouse, Vice-Chairman; Rear Admiral Robert E. Peary, Captain Charles J. Glidden, Charles Jerome Edwards and G. Douglas Wardrop.

Mr. Santos-Dumont is very enthusiastic concerning the market for American aircraft in our sister republics of the Western hemisphere. He says:

"Only one who is familiar with the economic and sociologic problems of the South and Central American nations can realize what aerial transportation will mean to them, and can understand the tremendous commercial and sociologic development and change to follow as the result of the application of aircraft to transportation. As has been pointed out, building railroads would cost between $100,000 and $200,000 per mile, and years of time, and the subsequent cost of upkeep and maintenance would far exceed the prospective income from countries of such sparse population. On the other hand, the sum of $100,000 would establish an aerial line across a distance of at least 500 miles, or more, where rivers or lakes can be used as landing places for aeroplanes."

While the Pan-American aeronautic movement is youthful, having been conceived by Mr. Henry Woodhouse in 1911 and evolved by him and the other energetic and farseeing men, who are responsible for so many important aeronautic movements—Messrs. Alan R. Hawley, Alberto Santos-Dumont, John Barrett, and Rear Admiral Robert E. Peary—it is advancing in gigantic strides.

The Pan-American Aeronautic movement is based upon the work of pioneers, some of whom were contemporaries of the earliest European experimenters in aeronautics. Brazil, for instance, rightly claims among its pioneers Bartolomeo-Laurenco Gusmao, who takes us back to 1709, and Augusto Severo.

Alberto Santos-Dumont, the Brazilion inventor and pioneer, was the first man to really go where he liked in an aircraft, which he did with his dirigibles in 1901, and the first man to fly an aeroplane outside of the United States, as well as to make a flight in public. He had been a pioneer in cycling and automobiling, and together, spent an enormous amount, probably over a million, in developing cycling, automobiles and aeronautics. In aeronautics he spent over $30,000 a year for twelve years in experimentation. For his substantial support to automobiling he was made an honorary member of the Automobile Club of America.

Australia Appropriates $1,500,000 to Aid Commercial Aeronautics

Australia has noted with interest the development of commercial aeronautics in the countries of Europe and throughout the United States and, feeling that success is assured, has decided to establish a department of her own. For this purpose an initial appropriation of $1,500,000 has been made by the Government and the assurance has been given that more funds will be supplied when the feasibility of commercial aviation in Australia is established. The present appropriation will be used for construction alone, and as the department expands larger sums will be awarded for the purpose.

In returned war aviators Australia has the nucleus for a training corps, for these men are ready to serve their country. They will be asked to assist and direct the construction of the merchant air fleet and to instruct the pilots and observers. The argument is advanced that the returned war fliers will obtain employment in this manner and at a rate of remuneration higher than in other commercial pursuits.

The transport of mail by aeroplane in the United States has been noted here, and the backers of the new movement assert that results in Australia will be greater than in America. In the United States, they point out, there is an excellent system of railroads and the transportation of mails always is speedy, but the aero delivery is faster. In Australia the railroad system is not so good, and the chances for the aero post to better the work of the railroads is infinitely better.

Transportation of passengers in countries of Europe has been the object of interest in Australia and the same argument is advanced that if it is a success there it cannot fail here. Later freight transportation will be taken up, provided, of course, that air delivery of mail and transportation of passengers proves successful.

At present the Government is the only organization interested in the development of commercial aviation here, but later it is expected that private capital will be attracted and that Australia will have a perfect system of aerial transportation for mails, passengers and express.

The News of the Week

Caproni Makes Record Flight from Dayton to Houston

Houston, Tex.—After being delayed for many days until Ellington Field was in suitable condition for landing the three Liberty-motored Handley-Page, a record flight between Dayton and Houston, 1,450 miles, was made in a flying time of 17 hours and 15 minutes. The first Caproni to negotiate this trip took seventy-eight minutes longer to complete the journey. Stops were made at Indianapolis, Belleville, Memphis, Roanoke and Dallas. Heavy rains held the plane for many days at some of these points, so that twenty-eight days were required to complete the flight. One thousand and eighty gallons of gasoline, or an average of 2 gallons per motor per hour, were used in covering the 1,450-mile distance at 84 miles an hour.

Flight Saves Oil Man's $250,000

Wichita Falls, Texas.—William Livingston, an oil magnate, narrowly missed losing $250,000 when he found himself unable to attend a business meeting at Wichita Falls. He received telegraphic advice at Fort Worth to come to Wichita Falls, but missed the last train.

Captain Will Erwin volunteered to take Livingston in his aeroplane. The trip was made at a speed of 119 miles an hour. After the deal was consummated, Mr. Livingston purchased Erwin's aeroplane and hired his services. Since then he has been making his business trips throughout Texas by aeroplane.

New York State Motor Federation Urges Municipal Landing Fields

Utica, N. Y.—According to an announcement made by Mr. John M. Ross, of the New York State Motor Federation, efforts will be made by that body to secure the establishment of municipal landing fields and the establishment of emergency landing places through the cooperation of property holders, as well as the passage of laws to assist aerial travel.

Captured Aviators Held for Ransom

El Paso, Texas.—Lieut. Paul H. Davis and Lieut. Harold G. Peterson have been captured by Villista bandits after a forced landing on Mexican soil, and are being held for a $15,000 ransom. The War Department is complying with the demand of the outlaws.

An official statement was issued by Brigadier General James B. Erwin, District Commander, that Major L. A. Walton commander of the aero unit at Fort Bliss, had received a message from Peterson, advising the payment of the bandits.

Lieut. Peterson was long stationed at Ellington Field, where he became known as one of the most skillful and daring exhibition fliers.

Aeroplane Delivery of Surgical Instrument Saves Patient

Philadelphia, Pa.—In order to save the life of a patient, Dr. Thomas E. Eldridge flew from this city to New York and return recently. Dr. Eldridge found it necessary to obtain a "Caldwell tube," which could only be had in New York. The trip was arranged by Dr. Bert Huyette, president of the Philadelphia Aero Service Corporation, and Paul F. Houser, formerly military aero instructor at Mineola, was engaged as pilot.

Elizabeth Constructs Air Markers to Guide Commercial Fliers

Elizabeth, N. J.—Official air markers for the guidance of airmen piloting passenger and commercial aerial transports of the future over Elizabeth, N. J., will be located in Wilson Park, near the Newark line, it was announced after a conference between Mayor Mravliag, Board of Works Commissioner Hand, Abe J. Davis, president, and Major D. Griffith, secretary of the Chamber of Commerce, and others interested in civil and city improvement.

The air markers as designed are three wooden or concrete structures, thirty feet in length, and will designate Elizabeth as Station J-78 on the air line route. These will serve as guides to direction and identification marks for the air pilots. The park will also be made available to the pilots as an emergency landing field.

New York-Cape May Passenger Service

Cape May, N. J.—A passenger air service between Cape May and New York is being established by D. A. Steele. City officials have given permission for landing the seaplanes of the projected service on the beach. A fare of $100, plus war tax, will be charged.

Aerial Mail Delivered to Adriatic at Sea

New York, N. Y.—The first aerial mail delivery to a ship at sea was accomplished on August 14 when an Aeromarine flying boat dropped a sack of European mail on the deck of the White Star liner Adriatic.

The feat was accomplished successfully in adverse weather conditions by means of an ingenious releasing device developed by the engineers of the Aeromarine Plane and Motor Company. The experiment was an official test undertaken at the request of the Postoffice Department, and may be put into general operation.

Shortly after the experiment, David Lindsay, of the White Star Line, announced the steamship companies would adopt the scheme also for delivery of ships' manifests after the ship has left port. In this manner, he said, fully eighteen hours can be saved to transatlantic liners. The liners will be able to take on cargo up to the last moment before sailing, and then receive the completed manifests by aeroplane delivery long after they have sailed.

The mail delivered to the Adriatic was placed aboard the flying boat at the Columbia Yacht Club on the North River. The mail sack was inclosed in a special waterproof bag.

Piloted by C. J. Zimmerman, the flying boat arose off the yacht club landing and made a speedy flight down the bay. With Zimmerman was his mechanic, Richard Greisinger.

The flying boat overtook the Adriatic just as she was passing out of the Ambrose Channel. After circling around the liner a few times, Zimmerman came down to within fifty feet of the ship's masts and dropped the mail bag.

A steel cable had been stretched between the peaks of the Adriatic's fore and main masts specially for this experiment. On the flying boat a flexible cable, 200 feet long, suitably weighted at one end, had been attached to the mail bag. A special form of shock absorber was included in this cable in order to lessen the tremendous shock expected from the landing of a 100-pound mail sack.

As Zimmerman came down he released the free end of the flexible cable. Then, carefully judging his distance, he drove his aeroplane straight across the ship's course. As the flying boat cut across the liner's bows the cable, which was dangling out at an acute angle in the wind, struck the wire stretched between the ship's masts, instantly becoming entangled in it.

As the aeroplane sped on Zimmerman released the mail bag, which flew out in a straight line until its cable stood out taut. This brought the shock absorbers into play, and they checked the descent with great success. The bag fell into the water alongside the Adriatic, but as the other end of the flexible cable was tightly caught in the steel wire between the masts it was an easy matter for the sailors to pull it aboard.

Immediately afterward Captain J. Ransom, of the Adriatic, sent the following wireless to the White Star Line offices here:

"First aerial mail delivered safely aboard at 2 p. m. Ransom."

Fully 300 passengers crowded around the promenade decks of the Adriatic and watched the experiment. Their cheers echoed down the bay as the bag was successfully hauled aboard.

The U. S. Aerial Mail Boat, which dropped mail aboard the Adriatic several hours after she left port

Airship Service to Link Britain and Central Europe Next Year

The Hague.—Plans for the new era in the aviation world, so long prophesied by the linking up of the whole of Europe by a network of services, are beginning to take concrete form, according to a cable dispatch to the New York *Times*.

Holland, it would seem, is about to become the connecting link between the Allied and Central European countries. The first aviation exhibit in Amsterdam has certainly helped the plans to take definite shape.

Vickers, Ltd., has just announced a combination of passenger and mail services which will help form the links of an aerial chain from England and France through Central Europe. The first service will be between London and Flushing by means of a Vickers flying boat. From Flushing, and in connection with the London service, there will be services all over Holland by Vickers-Vimy commercial aeroplanes to Rotterdam, The Hague, Maastricht, Amsterdam and Northern Holland. There will also be a circuit from London to Paris, Brussels and The Hague.

Another service in the preliminary stages will be started via Arnheim, Germany, to Central Europe, probably connecting with Berlin. There is a possibility that this service will connect with a Zeppelin service beginning at the end of August from Berlin to Friedrichshafen, connecting with Swiss steamboats on Lake Constance and landing at Munich on the way. For this a new type of commercial airship built since the war will be used.

The capital for the network of aviation services will be $5,000,000, partly Vicker's capital and partly taken in Holland. There is little Dutch competition, as the Dutch have practically no airship factories. They had no material for this purpose during the war and even most of the machines for the Dutch Army came from Germany, the parts being put together here.

Complete organization of the new plans is expected to be ready at the beginning of 1920. Handley-Page, Limited, has announced regular service between Amsterdam and London, beginning next week.

The Vickers manager in Holland expressed great surprise that America was not represented at the Amsterdam exhibition.

Taxying Seaplane Beats Fast Motor Boat

Atlantic City, N. J.—Earle Ovington, piloting a Curtiss "Seagull," won out in a surface race against the speedy Nymph II, owned by Louis Eisenlohe, of the Chelsea Yacht Club, the Redskin, the Teaser, and other well-known speed boats of the vicinity.

Racing from a standing start, the seaplane was outdistanced by the Nymph and Redskin at the opening of the unique contest, first official event of the kind in the history of yacht racing, because of the caution which Mr. Ovington had to exercise in keeping on the water. Disqualification was the penalty for flying.

When his marine competitors had gained a 50-yard lead the airman began to pick up and on the homestretch passed the Redskin. The seaplane worked up to even terms with the Nymph by the time the judges' buoy was only a half-mile away, and they came down in sight of the crowd nose and nose. Carefully guaging his distance Ovington opened up with a hundred yards still to go and won by nine seconds over the Nymph. So close had Ovington figured out how far the seaplane would travel at its finishing speed before leaving the water that he had not gone ten feet over the finish line before it took to the air. It was a fitting climax to the fine program that had been pleasing the crowds all the afternoon.

Cotton Plantations Inspected by Aeroplane

A plane has just been put into commission at the head offices of Goodyear Tire and Rubber Co.'s cotton plantations, at Phoenix Arizona, to enable the overseers to keep in closer touch with actual farming operations on the plantations.

In the aeroplane the manager of the two plantations, which are situated about 40 miles apart, each about 20 miles from the city, can reach either plantation in 15 minutes. Formerly it required nearly an hour to reach them, because of the adverse road conditions prevailing.

The plane is in charge of Lt. O. P. Johnson, a Goodyear employee who became an "ace" with our flying forces in France, his operations having been chiefly in and around Cambrai and Amiens.

This new method of permitting quick personal oversight of cotton-growing operations has many advantages over the former method of transportation by automobile. Recently a complete inspection of the 35,000 acres contained in both plantations was effected in less than one and one-half hours.

The Goodyear plantations are located in the Salt River Valley. The cotton grown in this valley is of a superior quality. During the war much of the cotton from this section was used in making wings for aeroplanes, although the greater portion of it found its way into automobile tires.

Passenger Service in Rhode Island

Newport, R. I.—A passenger-carrying service between Bristol and Newport has been inaugurated. The flying boat only takes a half hour for the trip. Several trips were made on the first day.

Exhibition Air Battle Thrills Boston Crowds

Nantasket Beach, Mass.—The thrilling battle in the clouds, which has been exhibiting here for some weeks, has attracted large crowds from Boston and nearby cities. The battle, involving all known stunts as practiced over the lines, is carried on daily by Lieut. Howard C. Brown and Lieut. Wesley L. Smith. A 3,000-foot parachute jump is made daily by Sergt. Murphy from a plane piloted by Lieut. Mark C. Hogue, director of the exhibition team. The night flight, involving the use of searchlights, colored fireworks and bombs, is particularly well received. The enemy plane, picked up by the searchlight, is downed in a flaming spiral dive, after the maneuvers of combat have been gone through.

Aeroplane Landing Field for Beaumont, Texas

Beaumont, Texas.—An aeronautical Club is being formed here for the purpose of establishing a landing field for aerial mail planes. The Retail Merchants' Association is assisting in the formation of the club, and the city has voted a tract of land to be utilized as a landing field.

Group of officers and men who are accompanying the All-American Pathfinders, commanded by Lieut. K. C. Leggett, in the transcontinental recruiting flight

The AIRCRAFT TRADE REVIEW

Duesenberg Engines to Be Made in Rochester

New York.—Announcement was made here by the Duesenberg Motors Corp. that the Rochester Motors Co., Inc., Rochester, N. Y., had acquired all manufacturing and selling rights of the Duesenberg designed and Duesenberg type automobile motors. Production already has been started on a four-cylinder Model G-3 engine, known as the Rochester-Duesenberg, as a development of the Model G engine produced by the Duesenberg company early in 1918, having a rating of approximately 75 h.p.

Sidney Waldon and E. H. Sherbondy Designing Light Car

Detroit.—Sidney Waldon, formerly vice-president of the Packard Motor Car Co., and later colonel in the Aviation Section, and E. H. Sherbondy, former experimental engineer of the Air Service, have taken an office in Detroit, where they are designing a lightweight car embodying many advanced engineering ideas. It is not expected that the car will be on the market until next summer, as considerable experimental work will be done with the preliminary model.

Commercial Aviation in Central New York

Utica, N. Y.—Commercial aviation has come to Central New York to stay. With aeroplane corporations operating in Albany, Schenectady, Utica, Binghamton, Cooperstown, Syracuse and Rochester, the greatest of interest is being taken in matters of the air. Practically every principal fair in New York State this fall will have its aerial stunting program. The Mohawk Valley Aeroplane Corporation at Utica has bookings including the following fairs: Gouveneur, Lowville, Boonville, Watertown, Ogdensburg, Malone, Herkimer and Vernon, with others in abeyance. The Syracuse Aero Club, through arrangement with the Curtiss Aeroplane Corporation, is arranging exhibitions at the Syracuse State Fair, Hornell, Warsaw and Rochester.

There are now three base fields under operation by the Mohawk Valley Aeroplant Corporation, which began business this spring on a $30,000 incorporation basis. The concern has the Glenn D. Wicks Field at Utica with hangar, the Edmond Genet Memorial Field at Sylvan Beach where a hangar is to be built this fall, and the Virkler Field at Lowville. The corporation also has the use of the Smith Field at Herkimer and emergency landing fields at various points throughout the central portion of the state. These fields are to be marked and their location published in the near future for the benefit of transient aviators.

Lawson Has Co-operation of Spokane Chamber of Commerce

Spokane, Wash.—The Chamber of Commerce here announces that it is cooperating with the Lawson Aeroplane Company in its project of a transcontinental passenger aeroplane service.

Bills to Simplify Patent Procedure Framed

Washington, D. C.—The Patents Committee of the Engineering Council has collaborated with the similar committee of the National Research Council in developing a scheme for the improvement of the method of dealing with patents in this country. The staff of the Patent Office is itself actively engaged in this effort. Out of the report prepared by the National Research Council, and approved and adopted by the Engineering Council as the report also of its Patents Committee, remedial legislation has taken form. Three bills have been introduced, known as H.R. 5011, a bill to make the Patent Office independent of the Department of the Interior or any other department, and to simplify the procedure of the courts with reference to assessment of damages or profits for infringements of patents; H.R. 5012, bill to establish a single Court of Patent Appeals, and H.R. 7010, a bill to increase the force and salaries in the Patent Office.

Flight Instruction at Speedway Field, Philadelphia

Philadelphia, Pa.—At the Speedway Air Field, the official flying field of the Aero Club of Pennsylvania, located at Warminster, the Philadelphia Aero Service Corporation has its first class in flying receiving instructions. For convenience in instructing, small classes of three members each are formed, the course consisting of 450 minutes actual aerial work.

The class now at the field consists of Sergt. Roy K. Musselman, late of the U. S. Army, New Holland, Pa.; Lloyd M. Marshall, New York, and E. W. Park, a native of Korea. Sergt. Musselman has had many hours' air experience, as he was in charge of the ground force of several aviation training fields in this country during the war. He is taking his course at the Speedway Field to qualify for a pilot's license. Mr. Marshall is a prosperous merchant in his home town and is taking up aviation as a sporting diversion. Mr. Parks proposes qualifying as a pilot and returning to Korea with a plane for exhibition work. He believes he will be the first Korean air pilot.

The students are under the instruction of Lieutenant Paul F. Houser, lately an Army Air Service Instructor. Curtiss JN-4 training planes are used, having dual control. Under the instructor's directions the pupil is gradually allowed to assume control until he is competent to handle it alone. He is then permitted to make his test flights for his pilot's license before Official Observers appointed by the Aero Club of America. The following officials of the Aero Club of Pennsylvania will observe test flights and recommend the granting of licenses: Joseph A. Steinmetz, president of Aero Club of Pennsylvania, Paul B. Huyette and Lieut. Paul F. Houser.

"Ace" Plane in Flight from New York to Alabama

Montgomery, Ala.—The first of an order for ten "Ace" planes was delivered to G. Mason Perry at Montgomery, who is the distributing agent for these planes in Alabama, Georgia and Florida, after a successful cross-country flight from New York. The performance of the "Ace," which is one of the first commercial aeroplanes produced in this country, was most gratifying. Exhibitions were given en route at various aviation fields.

Experimenting with Fire Extinguishers for Aircraft

Realizing that fire extinguishers of the carbon tetrachloride type are ineffective for aircraft in flight, extensive experiments are being conducted to design an extinguisher which will operate under all conditions of flight. Fire extinguishers now used on aeroplanes depend upon the formation of a gas about the fire which cuts off the oxygen supply. Although this type of instrument is useful to fit on a plane for use when it is on the ground being tested, and in the hangar, it obviously cannot function properly when the plane is in flight.

The Fyr-Fyter Company of Dayton, Ohio, makers of high-grade extinguishers, are conducting extensive experiments with a view of producing an extinguisher which will be a protection when the plane is in flight.

White Sport Monoplane Uses Motorcycle Engine

Los Angeles, Calif.—The George D. White Co., of Los Angeles, is manufacturing a small sport monoplane powered by a motor cycle engine. The plane is of tractor monoplane type with a wing spread of 23 feet, length 14 feet, weight loaded 390 pounds. The maximum speed with 18 h.p. is 50 miles per hour and the flight range 150 miles without re-fueling.

The fuselage is not of the usual wire truss type, but is braced rigid with steel tubing so there is nothing to slacken and get out of line in bad landings or rough usage.

The elevators and rudder are connected with steel tube shafts and no wires or cables are used. The rudder is of the balanced type for easy control and the control of the elevator is equally simple with all non-essential parts eliminated.

The elevator is in one piece with the rudder above and not split and in two sections as when the rudder is inserted between. The machine is built very low with the wheels attached direct to the fuselage bottom. The spring wheels take all the landing shocks and have none of the disadvantages of V type landing gears with rubber cord which rots and deteriorates rapidly, generally collapsing at unexpected times.

The motor is an 18 h.p. air-cooled Harley-Davidson or Powerplus Indian which turns over from 2,100 to 3,000 revolutions per minute. The Simex propeller is connected with a countershaft and is a slow speed type with a high pitch, allowing maximum power from the motor at an efficient speed of the blade.

Although the monoplane is manufactured complete and equipped with 18 h.p. motors, motors of less power have been used successfully including Indian, De Luxe, Harley, Excelsior, Pope, Henderson and others.

Praeger Addresses Dixie Highway Association

Demopolis, Ala.—Mr. Otto Praeger, Second Assistant Postmaster General, addressed the Dixie Overland Highway Association at its Sixth Annual Convention, held at Demopolis, Ala. Mr. Praeger stated that the aerial mail service has covered 272,628 miles and carried 11,845,980 letters since its inception fifteen months ago.

To-day eight Post Office Departments mail planes cleave the air daily, each carrying between 13,000 and 15,000 letters and traveling rain, blow or shine 1,900 miles each day.

The work of the Post Office aerial mail system, Mr. Praeger stated, demonstrates the possibilities of commercial aviation and the regularity with which schedules can be maintained.

"Let me cite a few instances," said Mr. Praeger, "in which the Post Office Department has contributed directly to the advancement of aviation. We have demonstrated the possibility of maintaining a dependable daily schedule by aeroplane the year round despite the assurances of so-called authorities to the contrary. We have encouraged men with promising devices when no other branch of the Government would lend them a helping hand.

"Through the encouragement given an inventor by the Post Office Department an improved compass is now in general use by aviators. This compass is a significant departure from the early aeroplane compass which was hopelessly useless at times because of the great tendency of the compass card to set up a spinning motion. The first of this better type of compass was built specially for air mail planes and was first used by the Post Office Department.

"We encouraged an inventor, who got no assistance elsewhere, in the development of a self-cleaning spark plug and one which would not crack or fuse in a high compression Liberty motor. That type of plug was developed on the air mail field at Washington and tried out and perfected on our air mail planes. There are several makes of such plugs now on the market.

"At the request of the Air Mail Service the Bureau of Standards started to work on a device to locate or spot accurately a landing field by sound at times of utter invisibility and that Bureau has invented and perfected a device that will enable an aviator blindfolded to locate unerringly the center of the field on which he is to land. This wonderful achievement of the Bureau of Standards has been accomplished on our air mail field and with the air mail planes.

All of the planes in the Air Mail Service are being made safe against fire by completely isolating the engine and gasoline compartments by asbestos fire walls, each compartment protected by pressure fire extinguisher system, and the mail itself is being safeguarded by non-inflammable canvas bags.

In concluding, Mr. Praeger urged opposition to any change in the administration of the air mail service which would subordinate it to a military organization.

OTTO PRAEGER, Second Assistant Postmaster General.

THE LIBERTY CAPRONI BIPLANE

THE Liberty Caproni Biplane is derived from the Type Ca-5 built by the Italian Caproni Company, which, together with the well-known Ca-3 and Ca-4 types have been in use on the Italian and French fronts during the latter months of the war.

The Liberty Caproni was developed entirely in America at the shops of the Standard Aircraft Corporation, Elizabeth, N. J., and later at the plants of the Fisher Body Corporation, Detroit, Michigan. The engineering was superintended by Captain U. V. De Annunzio, formerly chief engineer at the Caproni Works in Milan.

When the armistice was signed the Fisher Body Corporation had most of the dies and jigs ready for rapid production of these Caproni Machines which were scheduled to appear at the French front in January.

Like all the bombing planes of the Italian design, the Liberty Caproni has twin fuselages. Each fuselage carries a Liberty "12" engine with a tractor propeller and the center nacelle carrying a pusher. It is equipped with apparatus for day and night bombing work. Machine guns are carried at the front and rear of the nacelle. The front gunner's cockpit is arranged to permit of the installation of a 37 mm. gun. Arrangement is made for carrying the entire load of Mark I and Mark IV Bombs entirely enclosed.

The two fuselages, the elevator, and the stabilizer are built up in two sections to facilitate packing, transportation and assembling.

To make quantity production possible, special materials and parts have been systematically eliminated and replaced with parts and materials of American standard types and qualities.

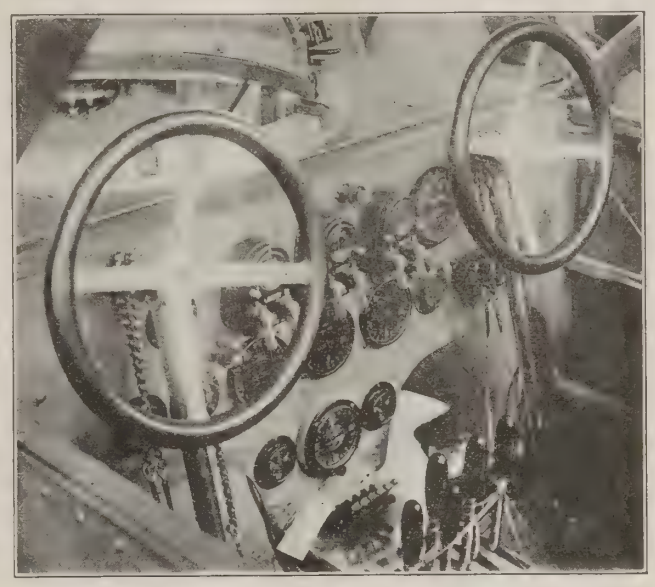
The general specifications of the Liberty Caproni are as follows:—

Dimensions

Span upper plane (measure taken on trailing edge)	76'-9-11/32"
Overall height (at aileron levers)	14'-9- 5/16"
Overall length	40'-9- 5/8"
Chord	9'-1- 3/4"
Gap between planes	8'-9- 7/32"
Gap to chord ratio	0.94'

Areas

	(*Sq. ft.*)
Main planes	1378
Stabilizer	78.892
Elevator	50.141
Rudders (each rudder 26,943 sq. ft.)	80.829



Weights

	(*Pounds*)
With full load for day bombing (A)	12818
With full load for night bombing (B)	13137
Weight per sq. ft. of wing area (A)	9.14
Weight per sq. ft. of wing area (B)	9.37
Weight per HP. (A)	12.20
Weight per HP. (B)	12.50
Weight distribution in % of totals (night bombing B):	
	(%)
Structural Weight	24.90
Power Plant	32.90
Fuel and Oil	21.30
Military or useful load	20.90

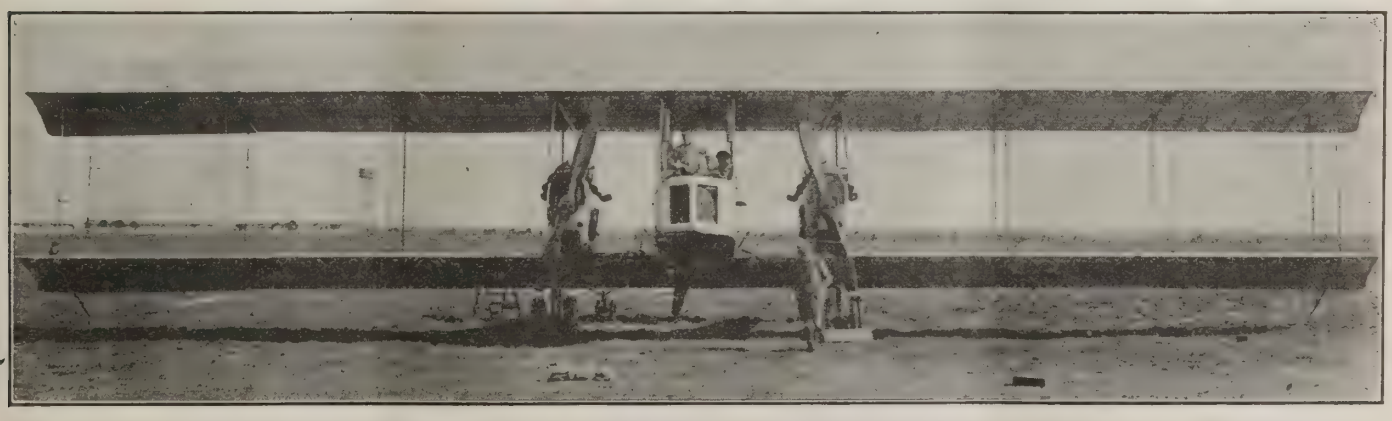
Performances

Climb to	*Time (minutes)*
6500 ft.	11
10000 ft.	22
13000 ft.	39
15000 ft.	56
Ceiling	70
Altitude	*Speed (M.H.P.)*
400 ft.	105
10000 ft.	96



Dual control and instrument board on the Liberty Caproni biplane

Main Planes

Main planes are built up in five sections, the corresponding sections in upper and lower plane being equal in length. The main section is the center lower section: nacelle, fuselages, power-plant and chassis are concentrated on that section, which arrangement reduces to a minimum the space required for assembly, and makes it easy to transport the central part of the plane on ordinary roads, the tail fastened to a truck and the machine rolling on its own chassis.

Intermediate and outer sections are fitted to the center section and to each other by means of male and female box-fittings and pins. The outer sections in the upper and lower plane carry the ailerons. The wing spars are in ash for the center section upper and lower plane and for the intermediate sections upper plane; in all the other wing sections they are in spruce; all of them are of box beam section and wrapped between rib and rib with strong linen. Like in all Caproni constructions ribs, double ribs and boxribs are of white wood and ash; the capstrip is screwed, not nailed. The internal bracing of the wings is as usual with cables

The American built Caproni biplane with three Liberty "12" 400 h.p. engines

and tie-rods. The covering is in grade A linen and nailed on the rib cap-strips and on the edges. Maple batten strips are screwed above the linen in correspondence to the ribs.

The interplane struts are seamless steel tubing with steam-lined wooden reinforcement, except for the four nacelle struts and the two rear fuselage struts which are ash. Transversally the interplane struts are braced according to the peculiar Caproni method. They are connected to the spar fittings by means of pins.

All lift cables are double except in the outer station. The landing cables are single. All of them are spliced and not soldered.

Steel sheet and oxy-welding are largely used for the fittings.

Angle of lower wing chord, 5°-30'.

Nacelle

The nacelle is a combination of the usual construction with longerons, struts and tie-rods and of the veneer structure. It is connected to the center wing sections by means of four ash struts. The general arrangement is similar to the one adopted in the precedent types of Caproni Bombers. In the front of the nacelle there is a cockpit with revolving machine-gun mount for the front gunner and observer. The two pilots are seated side by side back of the front gunner, from whom they are separated by a large dashboard on which all the instruments for the control of the power plant are disposed. Spark, gas and altitude adjustage are controlled for the three engines from a board situated between the two pilots. Back of that board and well accessible to both pilots is the gasoline distributor controlling the entire gasoline system.

The plane can be controlled by either pilot at will. As usual, a double foot bar and a double combination of wheel and stick control rudders, ailerons and elevation is provided.

The bomb-sighting device, the bomb-releasing mechanism, the shutters on the radiators, the camera, the lighting and heating system are all controlled from the pilots' seats.

Back of the pilots are two large gasoline tanks, followed by a big compartment limited by the front and rear wing spar of the center section lower plane and the lower longerons of the nacelle. This compartment contains the bomb-rack and a small seat for the rear gunner. The bottom of the compartment is fitted with three trap-doors, which are opened by the first bomb while dropping and closed at will by the pilots by means of a Bowden wire control.

At the rear end of the nacelle is the center engine with pusher propeller. The engine bed is supported by three braces of bass-wood, ash and ply-wood. Oil tank and oil radiator for the center engine are located so as to avoid long tubings.

Above the rear engine is a plate-form with a turret for the rear gunner, dominating the rear sector of the machine.

The radiators for the center engine are in the nose of the nacelle, while above the cylinder heads and close to the engine an expansion tank is provided. The nose radiators are surrounded by an aluminum cowl and fitted with shutters.

Fuselages

Both fuselages are identical. Each one of them carries on the nose one of the tractor engines. They are flat-sided and of the usual construction with four ash longerons, compression struts and tie-rods. The fittings are of sheet steel, designed so as to avoid bolts going through the longerons. The four longerons converge at the rear end of the fuselage in a steel tube terminal, which carries an elastic Pensuti tail skid. The terminal supports also one of the rudders.

Besides its engine and nose radiators, each fuselage contains two gasoline tanks, one oil tank and, along one side, an oil radiator. The fuselage is attached to the front and rear spar of the lower center section, while pins connect the engine beds to the V struts.

Chassis

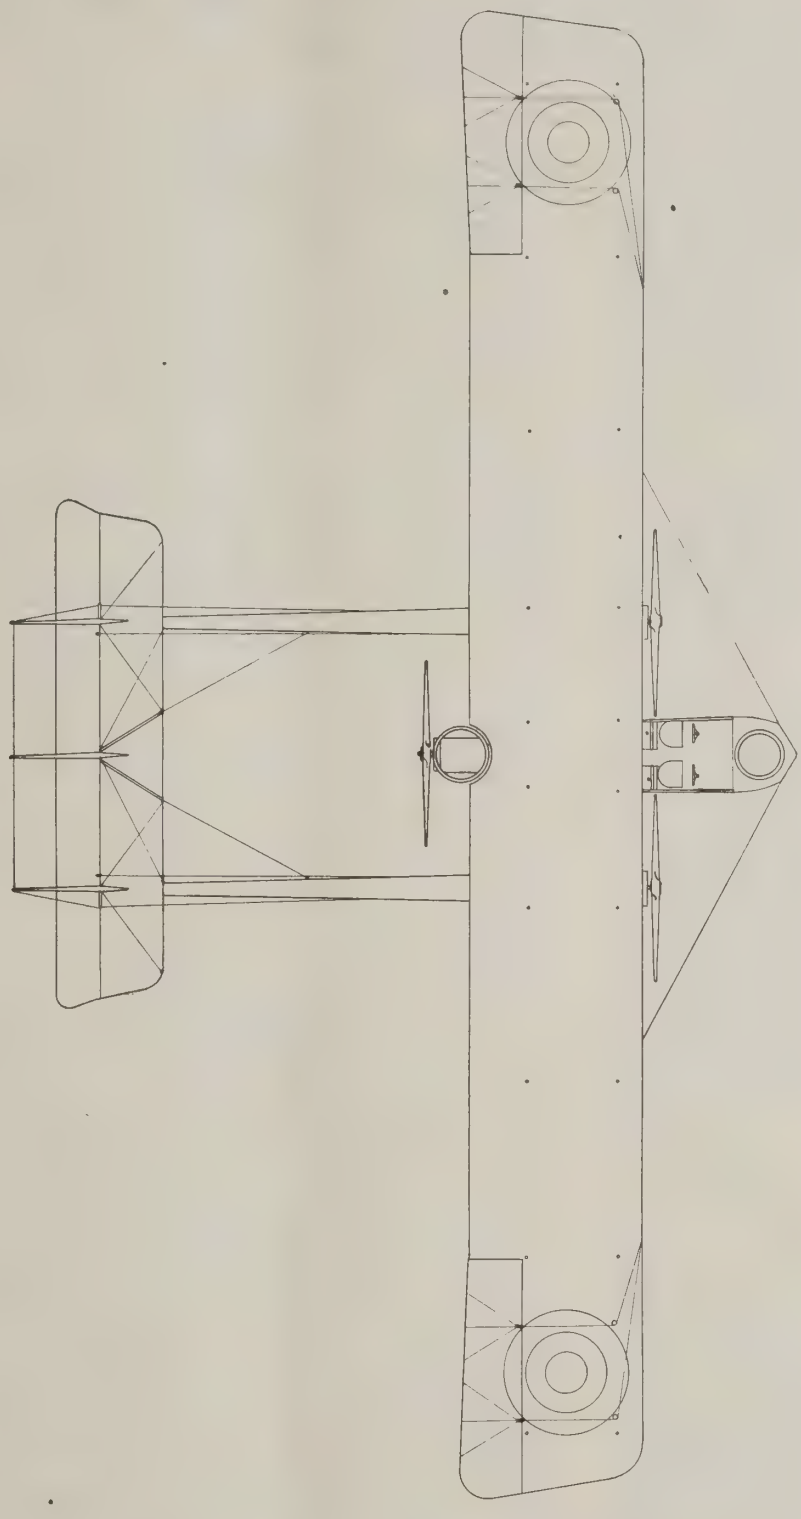
The chassis is of the usual Caproni type; the two U struts are of laminated ash and spruce wrapped with strong canvas fabric reinforced with a steel tube bracing. The wheel axles, one on each U strut, are kept in place by rubber chord acting as shock absorber and by two oscillating rods, ending at the front end in a universal joint which has its seat on the same fitting on which the main bracing cables of the chassis end. Each axle carries two double wheels over which mudguards are provided.

Control Surfaces

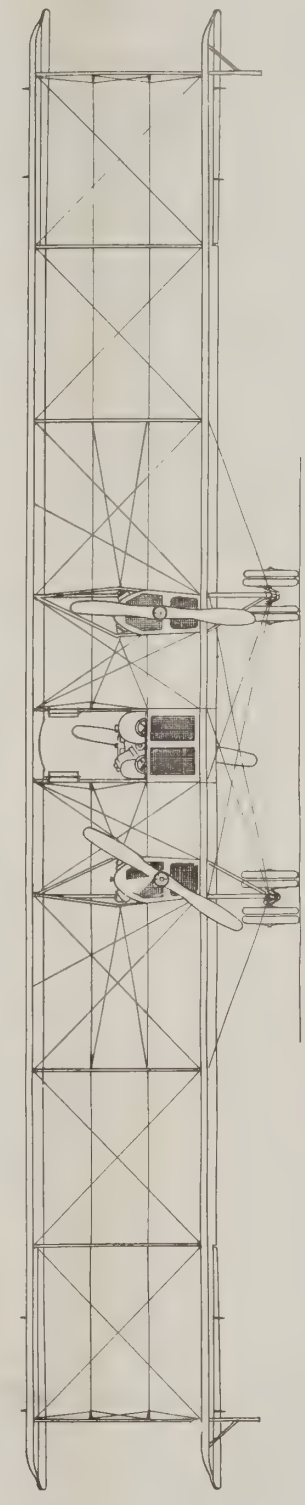
All control surfaces (stabilizer, elevator, rudders and ailerons) are of steel tube; the ribs of the stabilizer are stamped steel sheet. Rudders are balanced, braced with steel tubes and interconnected with steel cables. The stabilizer is braced to the fuselage terminals with steel tubes.

All levers are of stamped steel sheet and can be easily removed from the surfaces so that much space is spared in packing the surfaces themselves.

The control cables are carried on bronze pulleys fitted with ball-bearings. The cables controlling the tail surfaces are all double.



Power Plant



The machine is equipped with three Liberty-12 engines, Army type (high compression). Carburetors, ignition and

REPORT OF THE AMERICAN AVIATION MISSION ON EUROPEAN TOUR

(Concluded from last week)

IN the foregoing brief presentation of its conclusions, your Mission has touched upon the aeronautical policies already in effect or under present discussion in England, France and Italy. Great Britain's plan of orrganization certainly warrants our most careful consideration. Its salient points are clearly set forth in the chart herewith attached. It is not argued that the British method is perfect, but it can be stated without fear of contradiction in any quarter, that it stands today the most comprehensive governmental mechanism yet set up by any nation in the world for the encouragement, upbuilding, direction and control of its air resources. This organization has been born of five bitter years of trial, mistake, experience and progress. It is the product of the best brains in the British Empire focused under the spur of national need and the demand of the British people. We in America may well study it carefully.

Your Mission, in presenting its recommendations, desires to emphasize the view everywhere encountered that the future of aerial navigation and of aerial development generally, is in only a limited sense a function of military and naval establishments. The air is a medium for commerce and communication and its direction to the peaceful uses of civilization must be unhampered by the necessarily restrictive views of these specialized departments.

Recommendations

A. The concentration of the Air Activities of the United States, Civilian, Naval and Military, within the direction of a single governmental agency, created for the purpose co-equal in importance and in representation with the Departments of War, Navy and Commerce.

B. That the agency thus created be charged with full responsibility for placing and maintaining our country in the front rank among nations, in the development and utilization of aircraft for the national security, and in the advancement of the civil aerial transportation and communication arts.

C. That this governmental organization be formed in general as follows:

1st. A civilian secretary for air.

2nd. An assistant secretary, a civilian, responsible directly to the Secretary for Air, for the management and operation of the Department

3rd. Five or more Divisional heads acting as chief of the sub-departments of (a) Civil Aeronautics, (b) Military Aeronautics, (c) Naval Aeronautics, (d) Supply and Research, (e) Finance, etc.

4th. An Air Council, advisory in character, which shall be constituted by the Secretary of Air, including the Assistant Secretary of Air, the chiefs of the several sub-departments, and such other personnel as may be deemed advisable.

We desire especially to invite attention to the complexity and newness of the whole development of the Aviation Art, and to urge the broadest possible treatment of the subject during this formative period. We suggest that the lesser details of organization may well be left to the judgment and initiative of those called to assume the responsibility of directing this work. We desire also, in this connection, to call attention to the aircraft interests of the Allied Governments, and to emphasize the necessity for careful discrimination in the selection of men of industrial experience and broad vision.

D. The establishment of governmental institutions of education and training, including an air college, all open alike under proper restriction, to military, civilian and naval personnel.

E. Such curricular and such arrangement of promotion in the National Air Service, and such assignment and pay as to insure to the young man an attractive career, whether he elect to remain permanently in the "National Air Service" or return to Army or Navy, or to civil life.

F. The adoption of a system whereby Army, Navy and civil personnel can be circulated in proper proportion through the National Air Service. This personnel would, unless permanently assigned to Air work, be automatically returned to the Military and Naval sources, or to civil life as an Air Service reserve after the educational and service periods in the National Air Serice have expired.

It is felt that such a circulating system is vital to the coordination and ultimate efficiency of the three services, and to the desired dissemination of a knowledge of and interest in the Air among our people. The young officers of today will command the military and naval forces of tomorrow, and will carry with them into the highest ranks and intimate knowledge of aircraft, and of the strategy of its varied uses, in connection with operations on land or sea. The direction of civilian and commercial activities of all kinds will be made possible, and the closest contact and cooperation between the Government and the aeronautical industries assured.

All international relations touching aerial matters fall naturally within the jurisdiction of the Secretary for Air.

All responsibility for the Supply of Aircraft material and equipment of all kinds, and for the training of personnel for all branches of the service, is, in accordance with these recommendations of your Mission, placed with the Secretary for Air. As some twenty-seven thousand items are involved in the equipment and maintenance of each Air Squadron an active duty, the need for a single responsible direction seems undebatable.

Under this plan of organization here recommended, all squadrons and all equipment assigned by the National Air Service to meet the stated requirement of the Military and Naval establishments, pass automatically under Army and Navy command. Under National Air Service operational direction, remain only those independent projects unrelated to the activities of the Military and Naval fighting fronts and such personnel and equipment as forms a surplus to the needs of the sea and land fighting arms.

The question of governmental organization for the development and utilization of our country's air resources has been given consideration by your Mission, seemingly from every angle. The recommendations made are general. No report could be made effective, if burdened with the mass of details involved in the setting up of any governmental mechanism such as proposed.

There have been, and will continue to be advanced many objections to the establishment of a Department of the Air. We believe none of them will prove insurmountable. We believe the advantage gained to be such as to entirely overshadow any temporary difficulties.

Always in the past, in war by land or by sea, and in the transportation activities of peace, we have thought in two dimensions only. We must now readjust our minds to think for all future time in three.

When this Mission left the United States in May its members were hoping the Atlantic Ocean might be crossed before January 1, 1920. Within the two months of our absence, four successful crossings have been made and without the loss of a single life.

There must be no over-optimism. There are years of development and experimentation ahead. As in the case of all the other great agencies of civilization, the commercial and financially profitable use will come slowly. But here the immediate welfare and safety of our nation is involved and an intelligent and efficient direction of our aeronautical affairs will be demanded by the American people. American genius has given to the world the Airplane, a new instrument of commerce and of war. But America has left its development to other nations, and too late, realized the mistake of this neglect. She has paid the price! America now again has the opportunity, if not to lead, at least to take her place in the front rank and to gain to herself the full benefit which will surely accrue from an active and sincere cooperation in the engineering activities, and in the scientific and commercial aircraft developments of those nations associated with us in the war.

But this will be impossible, in the future as in the past, if our aircraft activities remain dispersed among the several governmental departments and impossible of coordination for decisive action.

Upon the breadth of view and the vision of those in control of America's policies, depends our future as an Air Power.

Commercial Development

With reference to the commercial development of aviation your Mission makes its recommendation based upon the following conclusions which have been formed, first, through knowledge of conditions existing at present in America, and second, the knowledge gained by its investigations abroad.

The investigations in England included visits to a number of factories, aerodromes and other points of particular interest, and interviews with the following gentlemen:

England:

Major General Hugh M. Trenchard, K.C.B., D.S.C., Chief of Staff, Air Ministry

Major General Sir Frederick H. Sykes, K.C.B., C.M.G., Controller General, Civil Aviation.
Major General E. L. Ellington, C.B., C.M.G., C.B.E., Director General Supply and Research.
General Huggins.
Mr. Douglas Vickers, Vickers Co., Ltd.
Captain P. D. Ackland, Vickers Co., Ltd.
Sir Percy Gerouard, Armstrong, Whitworth & Co.
Sir Samuel Waring, of Waring & Gillow, who is also interested in five other aeronautical companies in England.
Mr. Holt Thomas, Aircraft Manufacturing Company.
General Sir W. S. Brancker, K.C.B., D.F.C., Aircraft Manufacturing Co.
Mr. White Smith, British and Colonial Airplane Co.
Mr. J. A. Taylor, Cosmos Engineering Co.
Mr. Fadden, Cosmos Engineering Co.
Mr. Handley Page, Handley Page Co., Ltd.
Mr. Graham White, Graham White Co.
Mr. C. V. Allen, Secretary of the Society of British Aircraft Constructors.
Mr. Leslie P. Langton, Black and Manson Insurance Underwriters, who have specialized in aircraft insurance.

Factories of the following companies, engaged in the manufacture of aeroplanes and motors, were visited:

Members of the Mission also visited the airship factory of Armstrong, Whitworth & Co., located at Selby, and the dirigible aerodrome of the British Navy located at Pulham, where they examined the R-33, which is a replica of the R-34, and several smaller airships.

The Mission's investigation in France included visits to a number of French factories and flying fields, and interviews with the following gentlemen:

France:

General M. Duval, Directeur du Service Aeronautique.
Senateur Gaston Menier, Chairman of the Comite Aeronautique au Senat.
Mr. Pierre Etienne Flandin, Deputy, and former Chief of the Organe Interallie a L'Aeronautique.
Commandant D'Aiguillon, of the Commission Interministerielle de l'Aviation Civile.
Commandant de St. Quentin, Chief of the Service de Fabrication de L'Aviation.
Mr. Louis Breguet, of the Breguet Co., and Compagnie des Messageries Aeriennes.
Mr. Bleriot, of the Bleriot Co.
Mr. Maurice Leblanc, Bleriot Spad Co.
Mr. Kapherer, of the Societe Astru.
Mr. Bazaine, of the Societe Nieuport.
Mr. Maurice Farman, of the M. & H. Farman Co.
Mr. Granet, Secretary of the Chambre Syndicale de l'Industrie Aeronautique.
Mr. Esnault-Pelleterie, President of the Chambre Syndicale de l'Industrie Aeronautique.
Lieutenant Rene Fonck, Premier French Ace.
Mr. Maurice de St. Blanchard, Secretary of the Aero Club de France.
Comte de Libersee, former pilot and at present much interested in the development of civil aeronautics in France.

Among the factories visited were:

Morane-Saulnier factory.
Breguet factory.
Bleriot factory.
Farman factory.
Hispano-Suiza factory.
Renault factory.

All of which are engaged in the manufacture of aeroplanes and motors.

The investigation in Italy included interviews by representatives of the Mission with the following gentlemen:

Italy:

Signor G. Grassi, Deputy, Ex-Chief of the Italian Aeronautical Mission in France.
Colonel Guidoni, Italian Foreign Aeronautical Mission.
Admiral Orsini, Commander of Italian Aviation.
Captain Bursaglia, Chief of Staff to the Minister of Marine.
Signor Peroni, Director of the Ansaldo Co.
Signor Casatti, of the Caproni Co.
Signor Buzio, of the Macchi Co.

Representatives of the Mission also visited the following factories in Italy, all of which are engaged in the manufacture of aeroplanes, balloons and motors:

Pomilio Co.
Ansaldo Co., at Torino.
Caproni Co., at Milan.
Issotto-Franchini, which was shut down due to a strike.

1. One of the most important problems to be considered in the rehabilitation of the world's commerce, following the close of the war, is the development of aerial transportation for commercial purposes. Its one invaluable service, and that in which it surpasses all other means of transportation, is speed, that time-saving element which the world has always striven for, and for which America, with its great distances, has such serious need. Reliability, safety, economy, and those other qualities of transportation service which are of value, will steadly improve as the use of aircraft increases and experience accumulates.

2. It is as impossible to forecast the future of this new medium of transportation as it would have been to describe the speed, comfort and safety of the modern steamship at the time the first steamship crossed the Atlantic. It is safe to say, however, that in time it will become one of the great transportation mediums of the world and will continue to offer the fastest and most direct means of transportation for persons, mail, and light freight, known to civilization. Its development is limited only by the perfection of the mechanical devices used, with which we are constantly becoming more familiar, and by the extent of our knowledge of the atmosphere which is becoming more thoroughly understood each year.

3. It is equally difficult to determine the speed with which this development will take place. In fact, this will be determined largely by the opportunities afforded to employ the brains of the engineer and the scientist on the problems involved, which in turn will be controlled by the financial resources available for such work. It is thought by some well-informed authorities that the next five or ten years will see this new industry through its initial stages, and established on a self-supporting basis, providing it is encouraged at this time. Adequate support cannot be expected from private enterprise alone, and if no outside aid is given, ten years will probably see this industry in America still struggling for a foothold, and far behind its European competitors who will receive substantial aid of many kinds.

4. History has shown repeatedly that no nation can afford to neglect the highest possible development of its transportation mediums, regardless of the opportunities existing for immediate profit to the private enterprise concerned. This is particularly true of aerial transportation, which is not local in its nature, but which is essentially of a national and international character, due to the great distances covered, and to the speed with which it links together far distant points. This principle has been so clearly understood that an international agreement has been established between the Allies and their associates, by which international flight of aircraft has been provided for in a far-sighted manner, thus making immediately possible the flight of private craft from one country to another on a basis as clearly defined by law as that governing the movement of steamships, except, of course, that the practice of ages of ship travel is missing in the case of aircraft.

5. The development of aviation is progressing so rapidly at this time that it is difficult even for those in close touch with it to keep up with its progress. During the past two months the Atlantic has been crossed four times by aircraft; first, by a seaplane of the American Navy; second, by a an aeroplane of Great Britain, and, finally, by an airship of Great Britain which has twice demonstrated its ability to fly between England and America. All of this has been accomplished without the loss of a single life. Airships are now building in England which will be able to carry from five to ten tons of mail, in addition to the necessary fuel and crew, and cross the Atlantic from London to New York, in one-half the time made by the fastest steamships. Who can say such transportation facilities will not greatly serve civilization, and be of immeasurable value to our own country if properly developed and used?

6. Already lines of aerial transportation are being used in England and France in a small way for commercial purposes, but the distances in these countries are so short that relatively little advantage can be gained, so such ventures will develop slowly. A daily service from London to Paris has been in operation for some time, and promises to be quite serviceable as soon as it can be relieved of its war time military supervision. Other lines now in operation are from Paris to Lille and Brussels and from Paris to various points in Alsace-Lorraine and German occupied territory. Among other plans English private interests are projecting aeroplane lines from Cairo to the Cape and Cairo to Bombay, and French interests are planning to run a line to Algeria and Morocco. These lines will carry mail, passengers, and express, and it is expected that they will materially shorten the time between European centers and their far distant terminals. The United States Post Office Department has carried mail by aeroplane from New York to Washington for over a year with a record of nearly one hundred per cent delivery at each end every day. It is now inaugurating a line from New York to Chi-

cago which will shorten the mail time between these two points to about one-half. It is also projecting a two-day service from New York to San Francisco. England is already desirous of organizing with the United States a transatlantic airship line for mail service which would give a five-day mail service from London to San Francisco. Such a service is entirely possible at this time, and its inauguration depends only upon adequate encouragement and financial support.

7. The risks involved in these ventures, due to unknown conditions of the atmosphere, imperfections of equipment, etc., are still so great as to make them impracticable from the point of view of private enterprise, undertaken for a profit. If left entirely to such private enterprise, aerial transportation will develop slowly and with many losses and backward steps, as did the steamship, the railroad, and the automobile, each of which, however, has ultimately become a vital factor in our civilization.

8. One of the striking features of our investigation in Europe was the unanimous belief that the use of aircraft in warfare and for national defense would continue to increase and that in the next war, whenever it might come, aircraft would be a far more vital factor even than it has been in this war. One of the geatest military authorities in Europe stated that in his opinion the first battle of the next great war would be in the air, and would very nearly decide which side would win, in that the side winning in the air would immediately have acess to all of its enemy's sources of supply and production, and would quickly cripple them by air raids upon an enormous scale. The opinion was everywhere expressed that the development of aircraft for purposes of national defense must continue and that sufficient flying and production facilities and personnel must be maintained at all times to insure an adequate supply in case of need. Due to the complicated and delicate nature of such equipment, to its rapid depreciation in use, and to its constant obsolescence, the expense involved in such a program would be very great, in fact almost prohibitive in peace times.

9. The existence of an aerial transportation industry with a great commercial air fleet and of a strong production industry would greatly decrease the need for strictly military equipment and resources, in that practically all of the aircraft and landing field facilities and personnel, and the manufacturing and maintenance facilities and personnel employed by such commercial activities, would be available as a reserve in time of war. It is evident, therefore, that the most economical way to develop a strong air service for national defense is to encourage by every means possible the use of aircraft for commercial purposes, and thereby build up a commercial fleet at relatively small expense to the government, which would effectively supplement its strictly military equipment, in time of need. America's experience during the war has proven conclusively that aircraft facilities and technical personnel, and particularly production facilities and technical personnel, cannot be obtained upon short notice, but only by long and continued experience and at great expense.

10. America's production industry reached large proportions during the war, but since the signing of the armistice it has shrunken to a very small volume. Unless immediate attention is given to its conservation, it will practically disappear, and a considerable portion of the great sums expended in its development will have been spent fruitlessly. This industry does not require a large volume of business to keep it alive and healthy, but it does require a steady and dependable demand, otherwise private capital and enterprise will not long remain interested.

Recommendations

Upon the basis of these conclusions, we offer the following plan for stimulating the development of commercial aviation as an aid to national defense, and as a response to the demand that is already developing for improved commercial transportation though the use of aircraft.

A. The Civil Aviation Division of the National Air Service should establish with the advice of the Army and Navy, and the Divisions of Military and Naval Aeronautics, a series of flying routes throughout the United States and its possessions and to contiguous foreign countries, which will be of military and commercial value. It should also prepare and publish maps and descriptions of each of these routes, suitable for the use of fliers.

B. There should be provided at national expense certain flying fields in strategic locations, and suitable for military purposes, and encouragement should be given to the various States and Municipalities to provide flying fields upon all flying routes, at points found desirable, thus eliminating the necessity for private ownership of flying fields except for strictly private use. Hangars should be provided at each flying field by the governmental authority owning the field (that is, Federal, State or Municipal), or where such fields are used constantly by private interests, they should be permitted to provide their own hangars immediate adjacent to and opening upon such flying fields.

The operation and use of such flying fields should be controlled by Federal law, so as to obtain uniformity throughout the nation and conformity with international regulations.

C. All flying routes and flying fields should be equipped at national expense with signalling and communication systems, including wireless telegraphy, wireless telephony, and searchlights, to thoroughly safeguard and guide aircraft in flight. The Government's attitude in this matter should be the same as that maintained toward shipping in its lighthouse and coast patrol service. The operation of signalling and communication equipment should be controlled by Federal law for the reasons indicated under item "B."

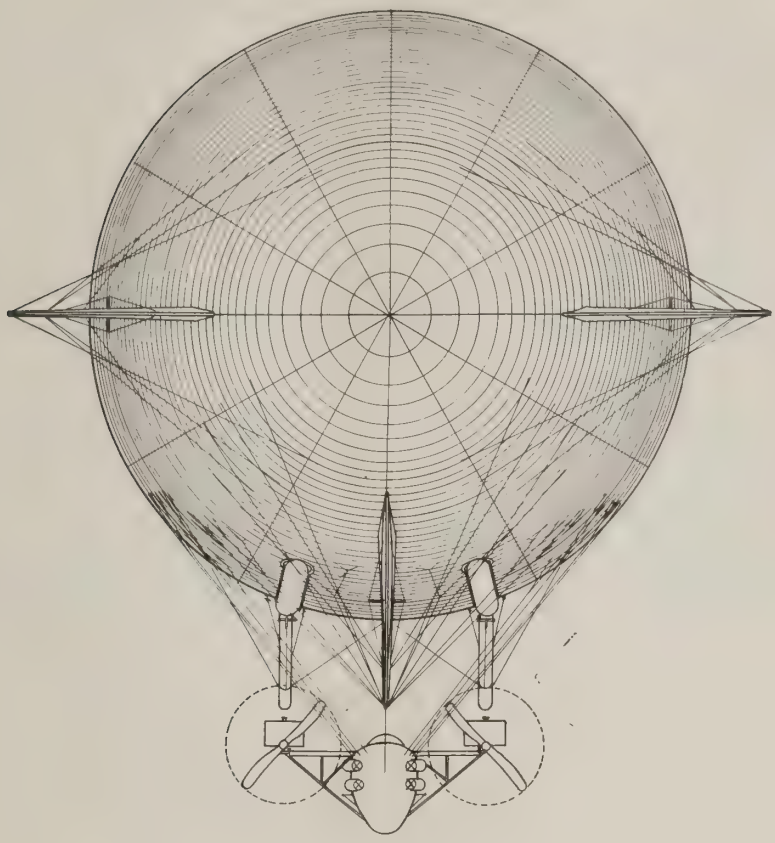
D. A meteorological service should be developed to provide fliers and other aviation interests with accurate weather reports and other atmospheric data necessary to govern their activities intelligently. The value of this service to commercial aviation cannot be overestimated, as it will go far toward establishing reliability and safety of service, just as weather reports are of immeasurable value to ocean and lake transportation.

E. Training facilities should be provided at various localities throughout the country, either at Government expense or by private enterprise under Government regulation, with guarantees from the Government of a sufficient number of students to cover expenses. Such guarantees could be given by the Government without undue expense if it used such schools for the preliminary training of its military personnel. Such a plan would encourage private enterprise to provide facilities for the training of the personnel needed for commercial requirements, which personnel in turn should become a permanent reserve for military requirements in time of need. There should be established at least one school for the teaching of aerodynamics and other branches of the science of aeronautics as recommended under the heading "Organization." Encouragement should be offered to universities throughout the country to establish departments of aeronautical science.

F. The Government should encourage the development of new design and aeronautical technique for commercial purposes along the lines recommended under the heading of "Technical Development."

G. The Department of Aeronautics should maintain the closest possible relations with all civilized nations in determining and applying the rules and regulations which will givern the international use of aircraft, and there should be developed as rapidly as is consistent with proper consideration a body of Federal law governing the use and air worthiness of aircraft for commercial purposes, which will safeguard life and property, and promote the commercial usage of aerial transportation.

In order that commercial aviation may be helped and not hindered by such legal restrictions, it is of vital importance that aerial transportation be recognized at once as an element of interstate commerce and be made subject to one body of *Federal* law applying uniformly throughout all of the United States. It will thereby avoid the complications of individual state control which have proven to be such a handicap to railroad and automobile operation.



H. Insurance of aircraft and its personnel against all kinds of hazards and risks involved should be encouraged in every way. The cost of such insurance should be kept as low as is consistent with the risks involved.

I. Encouragement should be given to the organization of private enterprises for carying on aerial transportation. This encouragement might well be in the form of payment for the carrying of mail and expressage, and of guarantees as to the volume of such business. Compensation might be paid to such enterprises for keeping their facilities available for use in time of war.

Guarantees of this kind coupled with opportunity to insure against loss by accident should make privately operated transportation lines a commercial possibility, but if it is found that private enterprise does not respond to such encouragement, then the Government should undertake certain transportation ventures on its own account and should continue to operate such lines until they are proven commercially successful. Ulti-

U. S. NAVY CLASS "C" DIRIGIBLE

STERN

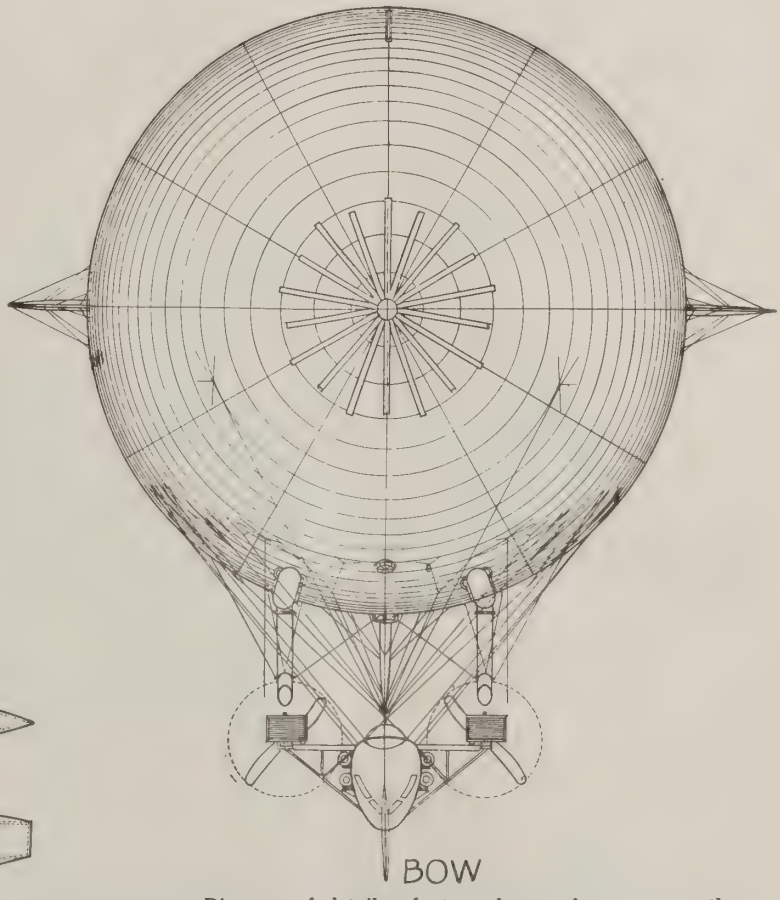
THE C type is the largest of the naval coast patrol dirigibles. It was the C-5, which established the long distance and duration record for American lighter-than-air craft by flying on May 14-15 from Montauk Point to Newfoundland in twenty-four hours and forty minutes, a distance of 970 nautical, or 1,115 statute miles. Unfortunately she was lost from her moorings within a short time of landing at St. Johns.

The C type is 192 feet long, 43 feet wide, and 46 feet high; it has a capacity of 180,000 cubic feet. Cruising speed, 42 M.P.H.; climb, 1,000 feet per minute.

The car is of streamline form, 40 feet long, 5 feet in maximum diameter, with steel tube outriggers carrying an engine at either side. Overall width of outriggers, 15 feet. Complete weight of car, 4,000 pounds.

The envelope maintains its form by means of internal pressure, obtained in the slip-stream of the two propellers through two blower pipes. These discharge into a duct leading to two ballonets. Two water bags fitted forward and aft in the bottom of the envelope aid in the trim control.

Longitudinal and latitudinal stability is obtained by fixed horizontal and vertical fins, and steering in the horizontal plane by a balanced rudder.



The suspension of the car and tail surfaces is made by patches, some fifty finger patches, each tested to stand a 2,000 pound pull, being required to support the car. Each patch consists of four strips of fabric shaped somewhat like the spread fingers of a hand, which are sewed and cemented to the envelope.

The power plant consists of two Union gas engines, water-cooled, of 6 cylinder vertical type, developing 125 horsepower at 1350 revolutions per minute. Less than ten gallons of fuel per hour are used at a flying speed of fifty miles an hour, while the maximum speed is 60 miles an hour.

These dirigibles are equipped with medium range radio transmitters weighing approximately 250 pounds. The antenna is mounted inside the envelope and is insulated throughout to avoid danger from sparking. A trailing antenna may also be used.

Seven passengers may be carried, but the usual crew consists of four. At the front, the coxswain is placed; his duty is to steer the machine from right to left. In the next compartment is the pilot, who operates the valves and controls the vertical movement of the ship, and aft of the pilot the mechanicians controlling the en-

Theory of Sprung Tail Skids on Aeroplanes

It is claimed at the outset that attaching springs to the tail skid of an aeroplane is more important than it is usually considered. The skid is attached to the fuselage by means of a pin joint at a joint at a point near its center and the upper end connected with the body by a spring. The oscillations set up when the lower end of the skid comes into contact with the ground on landing are examined from a theoretical point of view. It is supposed for simplicity that the landing wheels are rigidly attached to the ground, the aeroplane being free to move about the axle.

Let O be the point of intersection of the axle and the plane of symmetry, S the C.G., A a point on the fuselage vertically above the lower end of the skid. Also:

$r = OS$.

r_s = the horizontal distance from O to A.

ϕ = the inclination of OS to the horizontal

P = the reaction between the skid and the ground.

T = the moment of inertia of the machine about the axle of A.

G = the weight of the machine.

H and H' are the distances during oscillations above and below A_0. Suffixes 0 and 1 are used to denote the values of the quantities when the machine is in its *zero position* (i.e., when the skid just touches the ground, but does not bear the weight of the machine) and in its position of equilibrium respectively.

The equation of motion about the axle is

$$Gr\cos\phi - Pr_s = -T\frac{d^2\phi}{dt^2}$$

Consider the first oscillation between the zero position and the lowest point reached by A.

If $x = \phi_0 - \phi$ and K a constant depending on the spring,

$$P = P_0 + Kr_s x,$$

and it is found on integrating the equation of motion that

$$x/x_1 = 1 + C\sin a\,(t + t_0)$$

where

$$a = \sqrt{\frac{Gr\cos\phi_0 - P_0 r_s}{Tx_1}}$$

and

$$C = \sqrt{1 + \frac{2Gh}{x_1(Gr\cos\phi_0 - P_0 r_s)}}$$

where h is the vertical displacement of S corresponding to a rotation x.

These equations give the maximum value of x, and hence

$$P_{max} = P_1 + (P_1 - P_0)C.$$

Now $Gh = P_1 H$ approximately, and since the work done by gravity from zero to equilibrium positions is equal to the work done by the spring for the same motion,

$$Gr\cos\phi_0 x_1 = \frac{P_1 + P_0}{2}H'_1, \text{ also } r_s x_1 = H'_1.$$

After substitution, the final expression for P_{max} are obtained, viz.:

$$P_{max} = P_1 + \sqrt{(P_1 - P_0)_2 + 4P_1 Hk},$$

so that the maximum value of P that is likely to occur can be found if P_1, P_0, H, and K be known. In particular, if $P_0 = O$ and $H = o$, i.e., if there be no previous tension in the spring and tail of the machine drops only from the zero position.

$$P_{max} = 2P_1.$$

The equation loses its meaning, of course, if the tail of the machine cannot fall through a distance H_{max} without touching the ground.

Now, substitute $P_0 = P_{max} - KH'_{max}$ in the above equation for P_{max} and solve for H, then

$$H = \frac{2H'_{max}(P_{max} - P_1) - kH'^2_{max}}{4P_1}$$

H_{max} will, of course, have to lie between limits defined in the design of the machine.

The article includes the solution of a few numerical examples where also the length of the skid is considered, and concludes with a remark on the friction between the skid and the ground. (*Oesterreichische Flug-Zeitschrift,* December, 1918.) No. 4555.

Aviators Aid Astronomical Investigations

Arcadia, Calif.—The Smithsonian Astrophysical Observatory on Mount Wilson, under the direction of Mr. L. B. Aldrich, has made some valuable experiments with the assistance of the U. S. Aviation Service at Arcadia, Calif. A special instrument, the pyranometer, devised by Messrs. Abbot and Aldrich, measures the heat from the sun and sky combined, or from the sun alone, or from the sky alone, as it falls upon a horizontal surface. Mr. Aldrich used the pyranometer to measure the reflecting power of the large layer of fog which often covers the San Gabriel Valley, lying between Mount Wilson and the sea. A military balloon acted as support for the pyranometer above the fog, and the results were very satisfactory. The measurements are of much interest to meteorologists in consideration of the temperature of the earth, which is to a large extent covered with clouds.

NAVAL and MILITARY AERONAUTICS

Radio Telephone Concert for New York as All-American Pathfinders Start

New York, N. Y.—Uncle Sam's first aerial transcontinental recruiting expedition, known as the All-American Pathfinders, started from Mineola, L. I., on August 13, and one of the nine aeroplanes in the squadron, equipped with the new wireless telephone system, sent a farewell message and a Sonora phonograph concert from the sky as it passed over the city, to the people of New York.

Co-operating with the War Department, the Adams Aerial Transportation Company had a wireless telephonic receiving set erected in its offices in the *Times* building, with the aerials on the Rialto Theater. This installation was made by the International Radio Telegraph Company, which conducted the receiving end of the unusual demonstration. This company also furnished the Navy Department with the radio equipment used on the NC trans-Atlantic fliers.

A representative gathering of officers identified with the aviation sections of the Army and Navy, as well as many others prominent in the sphere of aviation, were present to hear the farewell message and music from the sky.

The aeroplane equipped with the wireless telephonic outfit was piloted by Lieut. J. E. Adams, while Lieut. C. C. Shangraw was the radio officer. Popular musical selections were sent and Lieut. Shangraw's appreciation of humor and topics of the day was demonstrated when he sent the following message: "I feel like a theatrical manager—I am way up in the air."

The demonstration proved to be a complete success and will be repeated over all of the 171 cities and towns on the itinerary of this great flight from New York to San Francisco.

Forest Patrol Fliers Pass 50,000-Mile Mark

Washington, D. C.—The Director of the Air Service announces that the five forest fire patrols now operating from Mather, March and Rockwell Fields have covered a total of 54,906 miles in 46,436 minutes during the seven weeks' period ending on August 8. In that time 452 flights were made and 91 fires discovered.

The summary of the work is as follows:

WEEK ENDING AUGUST 9, 1919

Squadron	Flights	Miles	Minutes	Fires
Mather Field (Ore.)	28	1,670	1,680	28
Mather Field (Cal.)	28	2,814	3,410	5
March Field (Cal.)	16	1,360	1,010	1
Rockwell F'ld (Cal.)	7	2,686	1,791	1
Total	79	8,530	7,891	35
Total for 7 weeks	452	54,906	46,436	91

Cross-Country Mileage Record Over 60,000 in Week

Washington, D. C.—The Director of the Air Service announces that a new record for cross-country flying was established during the week ending August 8. Army aviators flew 60,482 miles in that period. This mileage does not include flights given in the instruction of enlisted men.

Progress of the Dallas-Boston Fliers

Washington, D. C.—The Dallas-Boston fliers on August 10 had flown a distance of 4,211 miles in a time of 2,698 minutes. On that date a flight from Providence to Albany, 170 miles, was made in 90 minutes. A flight from Providence to Hazelhurst Field and return for supplies was made on August 9, a distance of 300 miles in 168 minutes.

1,000-Mile Inspection Flight in 760 Minutes

San Antonio, Tex.—Two DeHavilands, Lt. Leonard W. Jurden, pilot; Major Bruce B. Buttler, passenger; Commanding Officer of Kelly Field; Lt. Rex Stoner, pilot, Commanding Officer 8th Aero Squadron, and Capt. W. G. Renwick made a flight to McAllen, Tex., on a tour of inspection. Total mileage, 1,000 miles; distance of both ships: time, 760 minutes; altitude, 5,000 feet.

Mechanics Required for Aviation Mother Ship

Mechanically inclined men who desire to go to sea will be accepted for service aboard the U. S. S. Shawmut, the only aviation mother ship in the navy. Lieutenant Myron F. Eddy, flight officer in charge of aviation recruiting in the New York district, announced that the Shawmut is releasing aviation mechanics in accordance with orders received recently, and that the vacancies will be filled by recruits.

The Shawmut acts as tender for ten seaplanes and will be attached to the Atlantic fleet. Four of the seaplanes are carried on board ship. The other six are known as air boats—big seaplanes of the F-5 type. Air boats are flown from port to port, and engage in all fleet maneuvers. The Shawmut will proceed to Newport soon for aerial bombing practice and for seaplane observation of torpedo tests.

99 Per Cent. of Air Service Equipment Ready to Use

Washington, D. C.—The following statement was issued by the statistics branch, General Staff, War Department:

The latest reports from the Air Service show over 4,500 active type planes and over 15,800 active type engines at fields and depots, of which 99 per cent are in condition to use.

In the following tables are shown the status of the planes and engines at the Air Service fields and depots as of June 30, 1919:

	Total	In condition to use	Per cent of total in condition to use
Planes			
Experimental	346	346	100
Active	4,547	4,488	99
Obsolete	1,865	1,854	99
Obsolescent	2,670	2,544	95
Total	9,428	9,232	98
Engines			
Active	15,823	15,788	99.8
Obsolete	2,865	2,822	98
Obsolescent	10,457	10,117	97
Experimental	993	945	95
Total	30,138	29,672	98

Aeroplane Stocks Officers' Club Despite Railroad Strike

Fort Sill, Okla.—The Officers' Club at Fort Sill used aeroplane transport when local meat supplies were exhausted during a recent railway strike. A flight to Oklahoma City was made to procure 125 pounds of meat and a quantity of urgently needed electrical supplies.

The Post Field Aerial Baseball Club were carried in Curtiss planes to and from Marlow, Okla., in order to play a game scheduled there.

FOREIGN NEWS

Eight Passengers in Paris-Morocco Flight

Casablanca, Morocco.—The giant aeroplane Goliath, carrying eight passengers, which left the vicinity of Versailles at midnight Sunday, arrived at Morocco on August 11 at 5:40 p. m.

Strong Air Force to Reduce British Expeditionary Forces

London.—Winston Churchill, in urging strictest economy in regard to war expenditures, particularly in connection with the maintenance of expeditionary forces along the Rhine, and in Turkey and Mesopotamia, says:

"The government is making earnest inquiries whether it is not possible by free employment of armored cars and swift tanks and a judicious arrangement of railways and aeroplanes to greatly reduce our armies in these regions." He was hopeful that it might thus be possible to reduce the costly British forces by half.

Mr. Churchill argued, however, against abolishing the framework of the anti-aircraft organization on the ground that no form of attack could more easily or secretly be prepared than an air attack.

Major General J. E. B. Seely, Under Secretary for Air, in the course of his speech made the effective point that the efficient air force had saved the country millions in money and thousands in lives this year in connection with the troubles in Afghanistan and Egypt, where campaigns were carried out at slight cost as compared to the aforetime heavy cost in money and life in similar campaigns conducted by Lords Roberts and Wolseley.

With regard to the air force, Mr. Churchill declared he had instructed Major General Sir Hugh Trenchard, chief of the Royal Air Staff, that he must provisionally frame his scheme within the limits of twenty-five millions yearly, which was equivalent to about twelve millions in pre-war days.

The estimated appropriation for the air force of £66,000,000 ($330,000,000), the General added, was necessary to clear up war contracts.

D'Annunzio to Attempt Rome-Tokio Flight

Rome.—The *Popolo Romano* states that Gabrielle D'Annunzio will shortly start a flight from Rome to Tokio via Asia Minor, India, Tonkin and China. The flight is expected to take fourteen days.

Ban on Civilian Passenger Carrying Between London and Paris Lifted

London.—The Air Ministry announces that:—

For the purpose of taking part in the Peace Celebrations during the forthcoming week, in Paris and London, arrangements have been made with the French Government for the opening of Civil Communication by air between London and Paris, from July 13th-20th inclusive.

British machines visiting Paris will land at Le Bourget only, and French machines visiting London at Hounslow only, except in emergency.

All machines will cross the French coast between Calais and Boulogne, and the English coast between Folkestone and Dungeness.

All machines taking advantage of these facilities must be provided with, and carry, certificates of airworthiness, issued by their respective Governments.

Passports will be carried by all civilian personnel.

A full list of passengers showing their destinations will be carried by the pilot in charge of the machine.

No goods or merchandise may be carried.

It is to be clearly understood that during the week this temporary arrangement is in force, no machine will, in any circumstances, fly over Paris.

3,700-Mile Tour in Aerial Limousine

Paris.—According to the *Daily Express,* Jean Galmot has completed a 3,700-mile trip around France in an aerial limousine carrying six passengers. Many stops were made at historic points along the journey.

The London-Brighton Week-End Service

London.—A regular week-end service between London and Brighton has been inaugurated by the Avro company, leaving London Friday and Saturday and returning Monday. The charge is £5 one way and £7 10s return trip.

Aerial Patrol Discovers Secret Meeting

Belfast—An aeroplane making a "patrol flight" recently between Novan, on the east coast of Ireland, and Armagh, observed Sinn Feiners holding a meeting which had been forbidden.

The fliers reported and military police arrived as the meeting terminated. They arrested two men amid great excitement. The prisoners were later released.

Flies Through Arc De Triomphe

Paris.—Lieutenant Godefroy, a French aviator, performed, on August 7, the remarkable feat of passing under the Arc de Triomphe in an aeroplane flight.

Godefroy flew a machine with a wing-spread of 24 feet, which left him a margin of about 21 feet to get through the arch. He cleared the opening cleanly, gliding through with the motor stopped. After clearing the arch he turned on the power again and flew over the Champs Elysee. Exhibitions of motion pictures showing the flight under the Arc de Triomphe were prohibited by the police on the ground that the flight was made contrary to police regulations and was likely to encourage other dangerous feats.

The Prefect of Police asked the newspapers not to reproduce photographs, but they ignored the request. Managers of the motion picture theatres said they hoped Premier Clemenceau would permit the motion pictures to be shown.

Schneider Trophy Competition in September

The Jacques Schneider international trophy, last won by C. Howard Pixton in a Sopwith baby seaplane at Monte Carlo in 1914, will be competed for on Wednesday, September 10th, at Bournemouth. The water course will be over a circuit of about thirty miles, starting from Bournemouth and taking in Swanage and Christchurch. The distance this year will be 200 nautical miles instead of 150 as in 1914.

25,590-Foot Altitude with Passenger Claimed as World's Record

Paris—Maurice Walbaug, flying in an areoplane with one passenger aboard, claimed to have established a world's record on August 9th by reaching an altitude of 25,590 feet (7,800 meters).

London Flying Club Has Auspicious Inaugural

London, Eng.—The London Flying Club recently opened its clubhouse. There is a hall large enough to accommodate 2,000 members and with 50 sleeping rooms and an aerodrome of eighty acres where it is intended to maintain aeroplanes for the use of members, either for solo flying or as passengers in parties. A flying school for the teaching of aeronautics will be maintained.

The president is Lord Lonsdale, and the vice-presidents include Lord Willoughby de Broke, the Duke of Rutland, the Marquis of Cholmondeley, Viscount Curzon, Sir Arthur du Cros, Lord D'Abernon, Lieut. Gen. Sir David Henderson, Lieut. Col. Cecil Grenfell, Major Gen. Sir John Seely, Admiral Sir Edward Seymour, and Lord Ribblesdale.

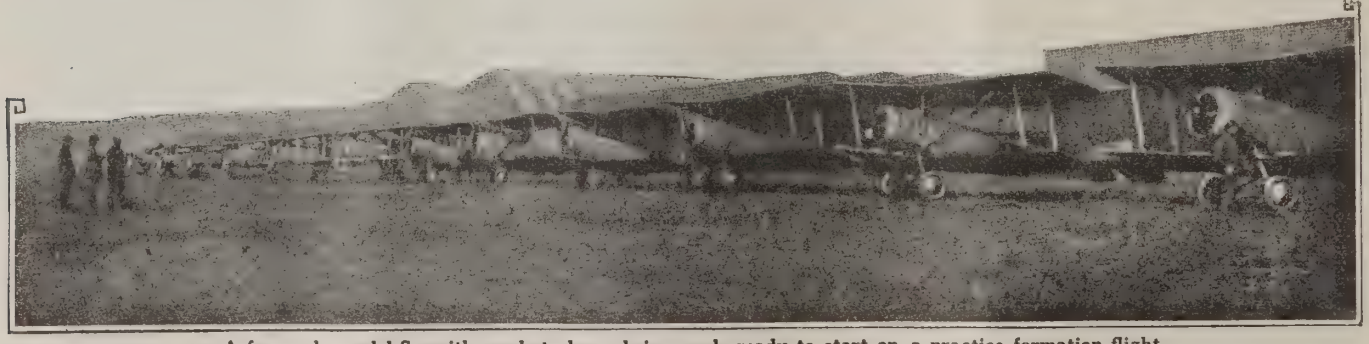
The Ritz Hotel is the London headquarters, and between the two a service of cars for the benefit of members will be maintained. The annual dues are 10 guineas, but present or retired officers of the Royal Air Force have membership privileges for 5 guineas.

Royal Jewels to Sweden by Aeroplane

The Copenhagen correspondent of the Central News reports that the police of Malmoe, Sweden, are holding two packages of jewels and securities dropped from an aeroplane and which they believe to be the property of the former royal family of Saxony.

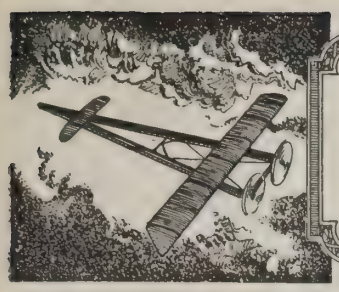
Coast guards saw the packages dropped from the aeroplane. They were picked up by two Germans, who claimed the valuables as their property. The police are investigating.

Mexican Air Service Growing



The Mexican Army Air Service has been gradually growing until it now numbers 500 aviators in various stages of training, while there are 6,000 applications on file. Colonel Alberto Salinos is chief of the Service.

Rice Growers of Colusa Employ Aeroplane Patrol



Rice growers at Colusa are contracting with a local company for an aerial patrol to protect 15,000 acres of rice from the ravages of ducks, geese and mudhens. It is believed the regular flight of aeroplanes over the fields at low altitude will so frighten the birds that they will leave for other parts.

Details of Turin-London Flight

London—Further information regarding the Turin-London flight, completed on July 16 by Lieutenant Brack-Papa in a Fiat B. R. biplane, accompanied by Lieutenant Bonaccini, is now available. The 225-mile distance from Paris to the Kenley Aerodrome was completed in one hour and three-quarters. On the previous day it had travelled from Rome to Paris (687 miles) in a little over seven hours, despite unfavorable weather conditions. Some days before the machine had been flown from Turin to Rome, doing the 362 miles in 2 hours, 15 minutes, an average speed of 161 miles an hour. This beat the record for this journey, the previous best having been 2 hours, 50 minutes, made by Sergeant Stoppani on a Sia machine.

A few early model Sopwith combat planes being made ready to start on a practice formation flight

ELEMENTARY AERONAUTICS and MODEL NOTES

By John F. McMahon

NOW that the Aerial Age contests are over, the model flyers of the United States should not let their work slide. Instead, they should keep building and flying models, both the racing type and the scale models, as we have promises from many influential men in the aircraft industry and other enthusiasts, that they will offer prizes in the near future. This should be given due consideration together with the fact Aerial Age will offer prizes again as soon as popular interests in models is proven by the model flyers themselves.

The rubber strand driven model has been the standard for years, but like every other mechanical contrivance, the model aeroplane must advance with the times and other forms of motive power should be experimented with and put to practical test to find something that will fly a model for at least one minute.

Many different types and kinds of motors other than rubber bands have been tried; the best so far have been compressed air and steam. Steam engines are complicated as the pump arrangement must be so designed and timed as to pump water into the boiler only as fast as it is turned into steam and used up in the cylinders. The pump generally pumps too much or not enough water, and the result is that the boiler gets cold from the excess of cold water, or it dries up in account of not getting enough. However, many successful steam motors have been tried, especially in England, with good results. Mr. Groves is the leading steam engine builder in the model aeroplane game.

The compressed air motor is less complicated and while it works on much the same principle as the steam engine, it is easy to construct and far easier to operate. The next contests will have one event for engine driven models. Points will be awarded in proportion for the type of engine used, whether compressed air, steam or gasoline. The last mentioned is out of reach of most model builders as it is necessary to have a lathe and other machine tools to manufacture it. The compressed air motor, on account of its simplicity, will be the most popular, no doubt, and the writer is in hopes that the existing record for a model powered with this type of motor will be broken.

Four years ago the writer had the pleasure of successfully flying a model rising from the ground and sustaining a flight of twelve seconds duration. This model had a twin cylinder compressed air motor and the flight was made at Highland Park, Brooklyn, N. Y. Later flights of longer duration were made at Wading River, L. I., for the benefit of the Wading River Mfg. Co., who purchased the rights to make and sell these motors.

As far as can be ascertained, these were the first successful flights in this country for models with compressed air motors. Later contests were held by the Aero Science Club of New York City, and records of 30 seconds were made with a model having a foreign engine.

The Wading River Mfg. Co. carries a full line of compressed air motors and plans for building. Their address can be found in the advertising columns of this paper.

To make a compressed air motor, it is necessary to have a sheet of .008" thick bronze 13" x 18" if wrapped straight, or 6" x 28" if wrapped spirally. This bronze is then wrapped around a former of wood and the laps of metal are soldered. Before putting on the ends, thin steel wire should be wrapped around the outside every ⅛" to strengthen it, after which the end caps are soldered on. These end caps can be purchased at any hardware store. Simply ask for curtain rod balls 2½" in diameter and split them in half. The outside half is the one used. A bicycle valve is used for holding the pressure, as well as a connection for the pump. This is soldered into place in the center of one cap. In the other, a gas cock is soldered for opening up pressure when ready to fly.

The engine cylinders are made up from fishing rod ferrules or brass tubing 1/32" wall, the pistons are of fibre, turned to fit the cylinders and tight enough to hold pressure and still move freely up and down. A rotating valve is made from a taper pin, and is so notched that it distributes the air as the crankshaft is revolved. In fact the crankshaft is nothing but a rotating valve, and by this arrangement much weight is saved.

Before the writer designed this style of open crank, having a crankshaft acting as an open air distributor, compressed air motors weighed as much as three ounces—the one mentioned above weighed 1⅛ ounce. The tank weighed but 7½ ounces, the complete model 15 ounces, and it had a wing spread of 52 inches. The surface was large for such a small machine, but it was necessarily so to insure success.

Complete data have appeared in previous issues of Aerial Age regarding compressed air motors, and for those who wish to get specifications of these particular motors should write to our Subscription Department for back issues of Aerial Age, and get your order in for the next issues which will contain valuable information to the model builders.

BOYS—ATTENTION

In order to keep up-to-date with the news of the "Model" world, you will want to receive a copy of AERIAL AGE every week, and because we realize that $4.00 seems a lot of money for some boys to spend at once, we have a very attractive offer to make. Write to us, addressing the Circulation Department, and we will tell you all about it.

Four members of the victorious Illinois Model Aeroplane Club team that won the Villard Cup and Aerial Age prizes. The names reading from left to right are: Lucas, Schweitzer, Jaros and Pease

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Taking Them Over

"Yes," said the little man in the train, "I'm glad the war's over; I could do with a rest."

"Ah! done your bit, you 'ave," said an old lady in the corner. "You're in the Air Force. Been at the Front?"

"Yes, mum, and I took over a thousand aeroplanes over the lines."

"Some aviator," interrupted one of the passengers.

"No, sir," replied the talkative one, "I'm some photographer."—*From Aircraft.*

Willie crashed his father's 'plane
Right through the front room window pane,
His father said, like one perplex'd,
"That youngster will be smoking next."
—*From Aircraft.*

Piker

"Macdougal is a bit close, isn't he?"

"Close isn't the word! He'd rather stay up an extra hour than come down and wear out the tires on his undercarriage!"
—*From Aircraft.*

Aboard the Trans-Atlantic Dirigible

A woman and he daughter were flying across the Atlantic during a terrific storm. After a silence of some time the mother asked:

"Are you seasick, dear?"

"No, I think not, mother," replied the girl, "but I'd hate to yawn."—*Awgwan.*

The arrival of the 6:15 express from Europe, by Ding in the "N. Y. Tribune"

A Bad Landing

Winsted, Conn. (from a press dispatch)—Hugh Rockwell, an aviator, of Plainville, is all "done up" as the result of his monoplane's landing in a colony of bees on August 4.

Before the aviator extricated himself from his wrecked machine he was attacked by hundreds of bees and stung in the face, neck, ears and parts of the body.

The engine, a light two-cylinder one, behaved splendidly until the last moment, but while nosing to the field the connecting rod in the cylinder broke and the plane came down, knocking over a swarming beehive.

Oh, death, where is thy sting!

Her Aeroplane Sermon

Grandmother there hears the engines of air—
  Sees the aeroplanes sailing by;
Sailing by and out of sight,
Under and over the rainbows bright,
  Higher than home birds fly!
Sailing on, through the dark and dawn,
And then like the light o' the rainbow—gone!

"It's the miracle time,
  That I've lived to see—
Man, like the wild birds,
  Flying free—
  God's good to you and me!"

Over the city the birdman's wings
  Hover and dart and seem
Like shadows—they say—
Now of gold, then of gray,
  Shadows you'd see in a dream.
And they fly to the east, and they speed to the west,
And the storm drives them home, like birds to the nest!

"It's the miracle time,
  Where the great wonders be,
But God's love is greatest,
  And that's all we see—
  God's good to you and me!"
—*Frank L. Stanton in The Atlanta Constitution.*

In a Military Manner

A reporter, in a camp where a number of negro troops were being discharged, asked one of them what he was planning to do when he got his release.

"Boys," said the negro, "the fust thing after Ah gets mah discharge, Ah goes and busts mah second lieutenant on the nose."

"Oh, no you ain't, nigger," spoke up another, "you is gwine to git in line and take yo' turn."—*American Legion Weekly.*

Can't Get Along Without Them

"Why is an airship unlike the Bolsheviks?"

Because it can get along successfully in spite of its propeller's "revolutions."—*Aircraft.*

(*Continued from page* 1094)

mately they should be sold to private enterprises on such terms as would permit of successful operation, as it is not believed that commercial aviation will ever be successfully developed under Government control.

J. The remaining aircraft production industry should be conserved and kept in a healthy condition by a well defined and continuing program of production for military purposes, over a period of years. This policy should be continued until the commercial demand is adequate to support an industry of sufficient proportions to form an effective nucleus upon which can be built a war time production in case of need.

Technical Development

With reference to technical development, your Mission in submitting its recommendations bases the following conclusions on a knowledge of conditions existing in the United States and upon extensive investigations conducted abroad:

1. (a) The Mission visited plants making or experimenting in materials as follows:

France—Breguet, Bleriot, Renault, Farman, Hispano-Suiza, Nieuport, S. P. A. D., Morans-Saulnier.

Italy—Ansaldo, Macchi, Caproni, Pomilio, Isotto (plant closed by strike), F. I. A. T.

England—Handley-Page, B. A. T., Rolls Royce, Phoenix Dynamo, Bristol, Vickers-Vimy, Cosmos, Sopwith, Grahame-White, A. B. C., Armstrong-Whitworth.

(b) The Mission has visited laboratory and experimental shops as follows:

Institute Sperimentale Aeroniutico, Rome.
Eiffel Laboratories, Paris.
R. A. F. Factory, Farnsborough, England.
Isle of Grain Naval Experimental Station, England.
Pulham Dirigible Station, England.
Aeroplane Station, Contocelli, Italy.
Dirigible Station, Craspiano, Italy.

(c) The Mission has interviewed the following Governmental official and industrial officers upon the subject of the proper organization, scope and equipment of the Technical Division:

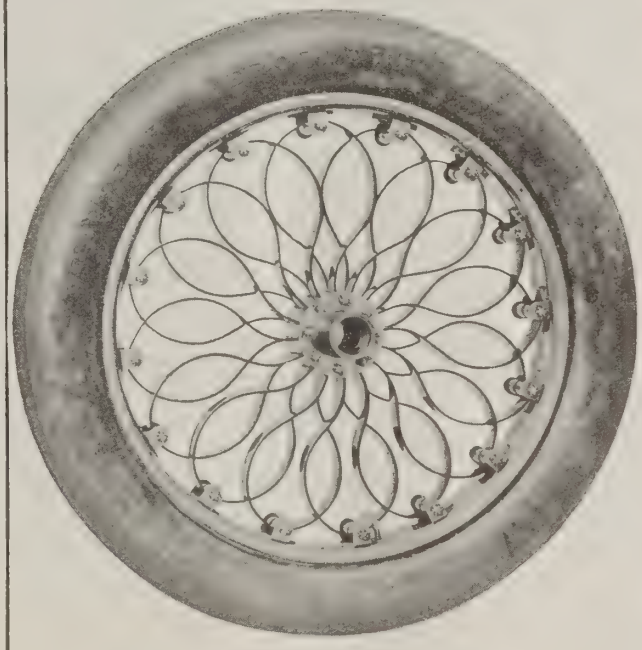
England:

General E. L. Ellington, Head of Department of Design, London, Royal Air Force.
Sir Percy Herouard, Managing Director, Armstrong-Whitworth Company, 8 George Street, Westminster London.
General Graves, R. A. F. Representative, with British Peace Commission, Paris.
General Brooke-Popham, Director of Research, London.
Mr. Holt Thomas, London.
Mr. Douglass Vickers, Vickers Ltd., London.
Mr. Grahame-White, Grahame-White Aircraft Company, London.
Sir Samuel Waring, London.

France:

Major d'Aiguillon, Interministeriello de l'Aviation Civile, Paris.
Mr. Louis Breguet, Manufacturer, Breguet et Cie, Cic des Messageries Aeriennes, Paris.
Mr. Cacquot, Former Chief Technical Section, Dept., Military Aeronautics, Paris.
Colonel Dorand, Department Military Aeronautics, Paris.
General Duval, Director Military Aeronautics, Paris.
Mr. Jacques Louis Dumesnil, Deputy, Former Under-Secretary French Aeronautics.
Captain del 'Estrade, Technical Service, French Military Aeronautics.
Mr. Pierre Etienne Flandin, Deputy, Former Chief Inter-Allied Organization of French Aeronautics, Paris.
Mr. Messaguer, Head of Hispano-Suiza Co., Paris.
Mr. Maurice de Saint Blanchard, Sec'y Aero Club de France.
Mr. Daniel Vincent, Deputy Director, Former Under-Secretary of Aviation, Paris.

Italy:



Commander Caldara, Head of Aviation, Technical Section, Rome.
Signor Casati, Designer, Caproni Co., Milan.
Lt. Col. Ferduzio, Designer of S. V. A. Rome Aeronautics, Rome.
Colonel Crocco, Director of Institute Sperimentale.
Colonel Guidoni, Italian Aeronautical Mission.
Admiral Orsini, Ministry of Italian Aviation, Rome.

2. The form of technical organization and control recommended by your Mission differs materially from the controll-

ing organizations in Italy, France or England. Inasmuch as for some time at least military, naval and departmental flying seems likely to lead in the development of the art, your Mission desires to lay emphasis upon the necessity of having these departments strongly represented in the operations of the Technical Division so that they shall be materially helped and not hindered in their research, experiment and development. To the same end we are of the opinion that lighter-than-air, which in England and France, due to the closeness of the war, the Technical Division is at present dominated by military personnel, but the opinion is unanimous that as time goes on civil personnel will supersede military in this division. General Ellington, England, expressed this opinion flatly and General Brooke-Popham, Director of Research, England, holds the same belief. In the Royal Aircraft Factory, at Farnsborough, civilian requirements are already overtaking military and naval. It has therefore been deemed wise to take the ultimate step at the outset in America, and a civilian head, of the type now earnestly sought in France and England, is recommended for America.

3. In equipment and personnel England and France and Italy are maintaining their war strength in the Technical Division. At Farnsborough we found a complete experimental plant, employing about 3,000 men and women and carrying on actively nearly every line of research, experiment and development in motors, planes and accessories. More than a score of planes, rigged with apparatus for aerodynamic experiment, were in the hangars and in the field. Physical and chemical laboratories seemed busy and fully manned. Estimating the lighter-than-air and the naval experimental and research personnel, it seems probable that the plant and the personnel engaged in the division in England is nearly, if not quite, equal to the entire trade in America at the present time. Obviously this branch of aeronautics lies at the very foundation of the future, both military and civil, and to fail to bring it up to the standard of the world cannot help but mean dependence and mediocrity or worse in aeronautics in America.

4. The inclusion of such topics as armament (Ordnance), wireless (Signal Corps), instruments (Admiralty), photography (Signal Corps), design and bombs (Ordnance), etc., has been found necessary in all countries. In reality the design and supply of such appurtenances is left to the departments or bureaus specializing in them, but research and experiment and development in methods of installation and use is essentially a function of the Air Service Technical Division and must be carried on by this division, both in the laboratory, on the factory floor and especially in the air, in the tank and on the field.

5. In all the European countries visited we found that access to and use of the Government owned facilities for development is established. The basis of such use varies and can be adapted to the circumstances. In all countries, however, the principle is the same, namely that private interests must obtain access to Government facilities, through the officers of the division, so that new inventions, etc., shall pass the scrutiny and criticism of the division heads before going into actual experimentation. In England an attempt has been made to furnish facilities at cost, but to save overhead, a schedule of flat prices is being worked out.

6. In England and France the question whether or not to design complete motors and machines no longer exists. France was forced to design aeroplanes in 1916, due to the failure of her private firms to meet the crisis created by the Fokker; but the immediate result appears to have been a quick return to the safer measures for encouraging the private designers to design and build, under the direction and assistance of the State. In England the complete design of aeroplanes ceased with the SE-5, and both Government officials and industrial officers offered ample testimony that the making of complete designs was a mistake and would not be repeated, due to its effect upon the private design departments. Without exception the manufacturers appear to take the view that it would be idle to compete by private efforts if one division of the Government was designing and another division buying, as the Government would inevitably favor its own designers, even though not quite so good. The result of such a policy, therefore, would be to limit the number of sources from which useful designs can be obtained, and also to lower the standard of personnel in the design departments of private firms.

7. In 1918 Sir Arthur Duckham, then Director of Aircraft Supply for England, said:

"As we all know changes in design, unless they are actually for new types, may be absolutely against production; most of our delays in production in this country and in the countries other than ours have been due to the effort to obtain too great perfection at too early a time."

Having this in mind and having in mind also the disastrous effects upon production of similar causes in the United States, your Mission asked explicit questions concerning the plan

AEROPLANE INSURANCE

Merchants Fire Assurance Corporation of New York

This company issues policies covering aircraft against the following risks:

1—FIRE AND TRANSPORTATION
2—COLLISION (Damage sustained to the plane itself)
3—PROPERTY DAMAGE (Damage to the property of others)

Additional coverage may be had against loss by wind storm, cyclone or tornado.

We will be glad to discuss problems concerning aeronautic insurance.

MERCHANTS FIRE ASSURANCE CORPORATION OF NEW YORK
45 JOHN STREET, NEW YORK CITY

AUSTEN B. CREHORE, Manager
For two years pilot Lafayette Flying Corps.
Since 1910 employed by this company.

FIRE—AUTOMOBILE—TORNADO—EXPLOSION—RIOT AND CIVIL COMMOTION

used by the Technical Division in England to minimize the result of such changes. The method is outlined as follows:

"All changes made necessary by the fact that a machine or motor is dangerous to the flier or to the public are classed as Number I. These are imperative and are ordered by the Director of Design, without delay. No machine is allowed to be accepted or flown without such changes having been made.

"Important changes involving improvement in performance, etc., are classed as Number II. Such changes are made by order of the Modification Board described below, and became effective only at such time as not to interfere unduly with production.

"Improvements and additions, not vital but often valuable, are classed as Number III. They are made when convenient, both to Government and to Contractor, and are not allowed to interfere with production or greatly increase price."

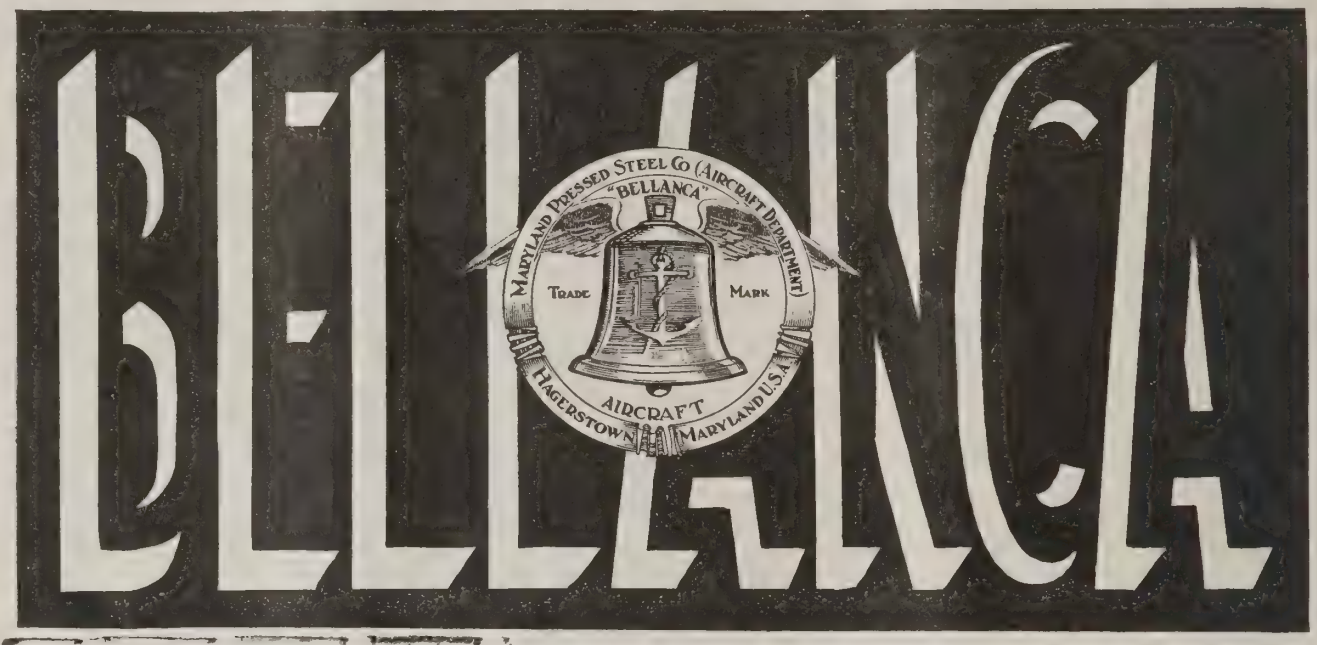
A Modification Board shall pass on changes and classify them. This board consists of five members, one from the Technical Division, one from Production, one from Operations, one from Finance and one from Supply. In the case of Number I changes the Director merely reports that such and such changes have been ordered. All other changes are ordered by the Modification Board at regular meetings.

Your Mission is of the opinion that the establishment of some such uniform practice, covering not only such changes but also the method of paying for them is essential to production and should be a responsibility of the Technical Division.

Recommendations

(a) That all technical functions of the Government in respect to aeronautics be centralized in a single Technical Division which shall perform the work for the Army, Navy and Civil aviation; and which shall be headed by preferably a civilian of wide executive experience. Such a division should include as Assistants to the Director experienced representatives of Army, Navy and other Government departments interested in aviation who shall be nominated by the departments and shall act as advisers upon the special needs of the service they represent.

(b) That steps be taken forthwith to secure for the United States the most advanced equipment for research, experimental and development work and for the testing of motors, planes, balloons, etc., for the testing of materials; for the examination and testing of aeronautical appliances, including armament and instruments; and that such an organization shall be established as shall assure at all times that the research, experimental and development activities of the Government shall be second to none.



(c) That the research, experimental and development facilities and equipment now used in aviation by the Army, Navy and other Government departments be inventoried immediately and put, as far as practicable, under the control of the Technical Division, retaining such of same as may seem suitable and bringing them under a central control to make a complete and efficient equipment and discarding such of them as unnecessarily duplicate others or are out of date. In making this change great care should be exercised to guard against measures which might tend to interfere with suggestions for improvements and advances in aviation, material and methods, coming from the operating aviation branches of the Army, Navy and Postal Departments. Experience has proved that the initiative in the advance of motors, planes and accessories often comes from practical experience in the flying field, rather than from the scientific department of aeronautics. The Technical Division will, in cooperation with the operating forces, study, work out and apply all such suggestions. Care should be taken also to avoid duplicating facilities already in existence, such as water tanks, armament testing grounds and many other items operated by existing departments. Arrangements should be made whereby the existing plants of this sort can be used on a proper payment basis by the Technical Division.

(d) That extreme care be taken in such a process of adjustment to provide ample means whereby the special technical needs of the (a) Army, (b) Navy and (c) Civilian flying shall receive attention. Means should also be provided whereby military and naval experiments of a secret nature can be carried forward.

(e) That the organization of the Technical Division cover by means of adequate personnel and equipment all branches of aeronautical research, experiment and development, including the application and aerial use of instruments, armaments and munitions, wireless telephone and telegraph, bombs and fittings, sights, fire fighting apparatus, parachutes, air bags and other safety devices, motor appliances for air service, propellers and photography.

(f) That all the technical facilities of the Technical Division for aviation, whether now existent or to be created, shall

THE MACHINE YOU WILL EVENTUALLY FLY!!

MARYLAND PRESSED STEEL CO., (AIRCRAFT DEPT.)
Sales Manager, HARRY E. TUDOR 299 MADISON AVE., NEW YORK CITY

be available to private inventors and designers upon proper and reasonable terms.

(g) That in view of the experience of England and France it is dangerous to allow the Technical Division to operate under normal or war conditions a department of complete design in heavier-than-air machines or in motors, as such competition results immediately in stopping private departments of design. The Technical Division, therefore, should be a critic of and supplementary to private design rather than aim at design on its own account. The policy of the Technical Division should be to maintain and encourage a considerable number of well-manned and well-equipped private design plants and to cooperate with these plants in all undertakings that meet with the approval of the Technical Division, and to place orders with these plants at fair prices for design and for experimental construction of motors, planes and appliances. Competition of the Government with the industry should be avoided; the only allowable exception being cases where, either on account of expense or for other cause, the Technical Division cannot obtain needed material or design from existing sources.

(h) That careful thought shall be given to the establishment of competition in motor, plane, balloons and accessory design, and encouragement be offered in every reasonable way to the promotion of competitive events and the establishment of standard records.

(i) That the Technical Division shall publish regularly and under competent management all the technical facts and data developed by the division that may be helpful to the industry, reserving at the same time to itself the right to preserve secrecy in all matters that are deemed to be in the nature of Naval or Military secrets.

(j) That such a Technical Division shall maintain at all times as close touch as possible with the development abroad and shall maintain representatives in Europe charged with the duty of liaison between the American and European technical organizations.

(k) That a definite method of payment for independent design, experimental production, changes in design, alterations and adjustments be worked out by the Government as quickly as possible to the end that the design and improvement of motors, planes, balloons and appliances may be stimulated and not stifled.

(l) That the Technical Division shall include an Inspection and Testing Department, which shall carry on all inspections and tests of experimental construction and revision, and which shall issue certificates of air worthiness for all machines for private and commercial use, and shall, from time to time, inspect all machines and appliances, including landing fields, signals, etc., used by the public. In cooperation with the Civilian Division, this department shall have power to limit and control all types of air machines used in commerce, and to test such machines before they become production models. This department should have power to examine the inspection methods of all private concerns building aircraft, and to pass upon the quality of such methods from time to time.

(m) That close cooperation be maintained at all times with the purely technical aeronautical bodies, and also with the industrial bodies engaged in aeronautics so that standardization of materials and practices may be carried forward as rapidly as can be done without hindering the development of the art or entailing undue losses upon the trade.

Respectfully submitted,

BENEDICT CROWELL, the Assistant Secretary of War.
HOWARD C. COFFIN, Member of Council of National Defense.

R. M. S. "Aquitania," July 19, 1919.

Memorandum No. 2.

Subject: Report of the Development Committee, American Aviation Mission.

1. I concur with the report of the Development Committee, to which I have affixed my signature, with the following reservation.

(f) Provided that nothing in the organization of the proposed Air Department shall restrict the Navy in the following activities:

(a) Maintenance of an organization adequate for the preparation of general specifications, general plans and characteristics of the aviation mechanisms, accessories and equipment required for Naval purposes.

(b) Maintenance of an organization and facilities adequate for carrying on experimental aviation work of a class that is exclusively of a Naval character, and that does not involve duplication of efforts and facilities in the proposed Air Department that are common to other aviation branches.

(c) Maintenance of an organization and facilities for conducting the acceptance and tactical tests of complete aviation mechanisms and accessories.

(Signed) HENRY C. MUSTIN, Captain, U. S. N.

The Liberty Caproni Biplane

(*Continued from page* 1091)

altitude adjustage are controlled by means of extra-flexible Bowden cables. The radiators (Rex Manufacturing Co.) are two for each engine and work in parallel.

Each engine has its own oil tank with oil radiator (of corrugated copper sheet) and by-pass, so that in cold weather the radiator can be excluded from the circuit.

The diameter of the propellers is 9′ 6″; the pitch, 6′ 6″. R.P.M. on the ground, 1,480.

Engines are inclined at a 2° angle.

Gasoline System

The gasoline is supplied by six tanks, disposed two in the nacelle and two in each fuselage. Each tank is divided in compartments, at the bottom of which check valves are fitted; those valves are working so that the loss of gasoline is always limited, in the event of one of the compartments being shelled, to the contents of the damaged compartment above the shell hole. The gasoline goes by gravity to the two wind-driven centrifugal pumps, which are fastened to the U struts of the chassis. From there it goes to a central distributor disposed between the seats of the pilots and easily accessible to them. This distributor has seven cocks, three controlling the pipes running to the carburetors of the three engines, two for the pipes coming from the two pumps, one for the pipe going to the two small auxiliary tanks, and one to evacuate eventual air bubbles from the system. The two nurse-tanks are attached to the front nacelle interplane struts, underneath the upper wing. Their principal function is to feed the engines, through the distributor, when the machine is on the ground. As soon as the wind-driven pumps begin to work, the small gravity tanks are filled again through their connection with the distributor. The over-flow sends the overflow gasoline back to the big fuselage tanks.

One alone of the two gasoline pumps is sufficient to feed the entire system.

Lighting and Heating

The lighting and heating system is fed by a wind-driven generator of 600 watts, combined with a storage battery.

Less Weight—More Mail

The use of the airplane in commerce has given a new value to savings of pounds and ounces in its construction—a value that is calculated in terms of dollars and cents profit.

Thus the big weight-economies effected in the Liberty engine by the use of 59 Lynite parts play an important part in the notable success of the U. S. postal air service.

Through its saving of from 350 to 400 pounds, Lynite permits more mail to be transported on each trip, makes possible greater speed and has other advantages.

Moreover, the greater heat conductivity of Lynite is an important factor, especially in the pistons, enabling the engine to perform better and travel farther without requiring overhauling.

Eighty-five per cent of all the aluminum alloy castings in the Liberty engine were made of Lynite or to Lynite formulae.

"DO YOU KNOW ANYBODY WHO IS BUYING A PIANO?"—GLENN H. CURTISS

ONE of these chronic pessimists who have been standing in the way of aeronautic progress was arguing with Mr. Glenn H. Curtiss that he could not see much of a future for civilian aviation.

"I don't know anybody who is buying a 'plane," he said, with a tone of finality, and apparently fully convinced that his argument was unanswerable.

"Do you know anybody who is buying a piano?" inquired Mr. Curtiss.

Of course he did not, nor do you, gentle reader. You do not ever know anybody who is buying a Ford or a hat or a pair of shoes. Yet the piano factories are as busy as ever—and the last report had it that Henry Ford had paid the best part of *one hundred million dollars* for the *minority stock* of the Ford company.

Nevertheless, over five hundred aeroplanes have been sold and delivered to individual owners since March, 1919, and the reason not over that number have been delivered is that the manufacturers were liquidating their government contracts and could not produce faster.

The demand is as great for $7,500 pleasure 'planes as it is for $2,500 'planes.

A great many buyers acquired Curtiss training 'planes because they could not get the "Oriole" type of pleasure 'plane—or any other type.

The first "Oriole" was built for the Second Pan-American Aeronautic Exposition, which was held at Atlantic City in May, 1919. It will be recalled Roland Rohlfs flew it to Atlantic City on May 1st in a storm, carrying the Hon. Victor Hugo Barranco, special representative of the President of Cuba, as passenger. By June the demand for this type of machine caused the Curtiss company to put it in production. It was decided to build ten, then twenty, then thirty-five, then one hundred and thirty-five. We will not give away a trade secret by stating the present number of "Orioles" and flying boats sold to-day, but we may state that over one hundred people are waiting patiently—and some impatiently—for deliveries.

Here is another case. A well-known veteran aviator secured the agency for second-hand military training aeroplanes and inserted five advertisements in AERIAL AGE. He got over four hundred orders and inquiries—but has been unable to get 'planes fast enough to fill the orders. Another AERIAL AGE advertiser had only one 'plane to sell and wanted $7,500 for it. He sold it—and had a score of prospective customers to spare.

AERIAL MAIL PLAN SAVES $170,000 YEARLY

"THE aerial mail service between New York and Washington and New York and Chicago has already saved the country $170,000 a year over the railway mail, and when the multi-motored aeroplanes are in operation there will be an annual saving of $1,500,000."

Assistant Postmaster General Otto Praeger made that statement before the Cleveland Chamber of Commerce, which held an aviation week in celebration of the one hundred days' perfect mail service between Cleveland and Chicago.

"During the one hundred days," said Mr. Praeger, "the Cleveland--Chicago division has been in operation the mail ships have flown a total of 65,000 miles and carried more than 3,000,000 letters. It has brought the East and Middle West closer together by sixteen hours, and the Atlantic and Pacific coasts by twenty-four hours.

"We have given you a demonstration of what the aerial mail can do, and it rests with the people now to tell Congress what to do."

Alva Bradley, chairman of the aviation committee of the Cleveland Chamber of Commerce and vice-president of that body, read the following resolutions adopted by the directors of the chamber:

"*Whereas,* For the past one hundred consecutive days the aerial mail service between Cleveland and Chicago has been operated successfully, thereby demonstrating the practicability of mail transportation by this means; and

"*Whereas,* The aeroplane terminal facilities in both Cleveland and Chicago are inadequate to accommodate even the present limited traffic; and

"*Whereas,* Owing to the increase of aerial transportation, an urgent need for Federal regulation of aircraft traffic is apparent; now, therefore, be it

"RESOLVED, That the Cleveland Chamber of Commerce urges upon Congress the desirability of enacting suitable legislation regulating aircraft traffic, and that the Chamber of Commerce further petitions the Post Office Department, in co-operation wherever practicable with the military and naval aviation services, to extend the aerial mail service as rapidly as possible throughout the United States, and especially to provide suitable terminal facilities in those cities where such mail service is now in operation."

Mr. Praeger said he expected the aerial mail to be in operation to Minneapolis, Omaha and St. Louis by early spring, when multi-motored ships, carrying as much as 3,000 pounds of mail, would be available.

Colonel Dunwoody declared that the European nations, and Great Britain especially, were encouraging aviation, and warned that unless the aviation industry of this country were given the benefit of a fixed American policy it would rapidly die out, with the result that when America again wanted an air service it would find it had none.

As a result of the joint activities of the Cleveland Aviation Club and the Cleveland Chamber of Commerce twenty-two Ohio cities, including Cincinnati, have set about establishing landing fields within the week.

THE NEW YORK-TORONTO-NEW YORK RACE

THIRTY-SIX military and three civilian aviators participated in the New York-Toronto-New York race for which John McE. Bowman offered $10,000 in cash prizes and the American Flying Club and the Canadian National Exposition offered a trophy.

The Prince of Wales did not start the race from Toronto, as had been announced. He was not present for the start. The start from Toronto was made at Leaside, a suburb of the city, though most of the judges were at the exhibition grounds.

Twenty-eight planes made the start from New York and eleven from Toronto.

The first plane to arrive from Toronto was the De Haviland 9A, piloted by Sergeant C. B. Coombs, who covered the distance in 6 hours and 21 minutes, reaching Roosevelt Field at 7:11 P.M. Roland Rohlfs arrived seven minutes later, and he was followed by Major R. M. Schroeder, who landed four minutes after him.

The first plane left Roosevelt Field for Toronto at 1:57 P.M. The start had been delayed for five hours by rain. Three planes from New York were wrecked on landing at the Albany field, and many others had to abandon their journey at various points along the route owing to engine and other troubles.

Of the total thirty-nine machines, thirty-two reached Albany. Six of these had made the start in Canada and twenty-six in Mineola.

Three of the fliers who entered in the air race have completed the round trip as we go to press. All are Americans.

Lieutenant M. B. Plumb, flying a De Haviland 4, alighted at Roosevelt Field, Mineola, at 5:50:30 o'clock in the afternoon. He had started in the morning from Syracuse, where darkness overtook him Monday evening, and had flown to Toronto, starting from the Canadian city on his return trip about noon.

Better time, apparently, was made by two fliers who finished at Toronto, whence they had started Monday, Major Rudolph Schroeder, who flew a VE-7, arrived at Leaside Park, just outside the city, at 5:20 o'clock. His actual flying time, according to his log, for the 1,000-mile trip was 9 hours and 25 minutes.

Colonel Gerald Brandt, another American, who also had started from the Canadian point of departure, arrived a few minutes after Major Schroeder.

Eight new entants started from Mineola Tuesday morning. Major Schroeder, Sergeant A. B. Coombs and Roland Rohlfs, who arrived at Roosevelt Field Monday evening, started northward early in the day, and five others who had started from the Canadian end of the race, arrived at Mineola and departed on the return trip before the close of the afternoon.

Several accidents occurred. Lieutenant Austin Crehore, of New York, one of the new contestants, was seriously injured in making a landing at Albany while on his northward trip. His arm was broken and he received possible internal injuries. Others put out of the race by mishaps included Captain Steinle, whose SE-5 was smashed while making a landing at the control station at Buffalo, and Major Elliot Spring, whose plane developed engine trouble and forced him to descend near Batavia, N. Y.

Following is a list of the contestants and the types of machines used:

Lieut. P. H. Logan (Le Pere), Capt. J. C. Foote (L. W. F), Major Elliot Springs (L. W. F.), Capt. O. E. Simonian (De Haviland 4), Lieut. Chas. Colt (SE-5), Capt. J. O. Donaldson (SE-5), Lieut. Wm. C. F. Brown (De Haviland 4), Major Lewis Hasslitt (De Haviland 4), Lieut. R. F. Midkiff (De Haviland 4), Major J. W. Simons (De Haviland 4), Capt. Steinle (SE-5), Capt. R. S. Brown (SE-5), Lieut. Ben Adams (De Haviland), Capt. F. E. Kindley (S-5), Lieut. M. J. Plumb (De Haviland 4), Major Gilkinson (Curtiss), Capt. H. B. Chandler (JN-4 H), Lieut. N. R. Taylor (De Haviland 4), Lieut. L. W. Bertand (Curtiss training), Capt. Richard Depew (JN-4 D), Major J. L. Lyons (JN-4 D), Lieut. B. N. Maynard (De Haviland 4), Lawrence Sperry (Avro), Colonel U. G. Jones (JN-4 H), Lieut. Melville (Caproni), Capt. Reynolds (De Haviland 4), Lieut. William Coates (De Haviland 4), Colonel G. C. Brant (De Haviland 4), Lieut. Ross Kirkpatrick (De Haviland 4), Lieut. H. H. George (De Haviland 4), Capt. A. B. Crehore (SVA), Lieut. R. Rolfe (Curtiss), Roland Rholfs (Curtiss), Sergeant A. B. Coombs (De Haviland 4), Lieut. C. A. Schiller (JN-4), Capt. H. W. Cook (Fokker), Capt. S. S. Moore (JN-4), O. S. Palmer (Curtiss), Bert Acosta (Curtiss), Colonel William B. Barker (Fokker).

On Tuesday evening the leaders in the race on Monday were well behind. Sergeant Coombs left Albany before noon, and though reports had not been received from him it is estimated that he must have got to Syracuse. Rohlfs, Barker, Schiller and Acosta were an hour or more behind him, with no definite reports after they had left Albany.

Those who should finish at Mineola during Wednesday are Col. Hartney, Lieut. Colt, Capt. Simonin, Lieut. W. C. Brown, Major Simons and Lieut. Midkiff, the last two squadron mates of Plumb.

So far the only civilian flier to make a showing is Roland Rohlfs.

Plumb was enthusiastically greeted at Roosevelt Field. Officers and enlisted men had been straining their eyes for an hour, knowing that he was on the way from Albany. As soon as his plane was heard a hundred strong glasses were turned upon it. The moment the number was read a cheer went up that could have been heard in Hoboken. Men from all parts of the camp rushed to the field to welcome him.

And when he had climbed out, shaken hands with Col. Archie Miller and other officers, he climbed back in again, posed a moment for the photographers and movie men, and rose in the air. Once up he put his plane through some of the most thrilling stunts that even Roosevelt Field has ever seen, as if to show that even a thousand-mile race couldn't bother her. Then he hopped over to his home station at Hazelhurst Field and went to bed.

Plumb's flight yesterday was nervy from end to end. Between Buffalo and Syracuse he was compelled to land to replenish the water in a leaky radiator. He made the landing in a cornfield, horror of all aviators, made it successfully, filled his tank, tied up the leaky place with a bit of towel and got away again in perfect form.

Fire was his other peril. Shortly after leaving Buffalo a piece broke out of his exhaust pipe and flames swept up into his face in the cockpit. He was obliged to drive the rest of the way with reduced gas pressure in order to save his face from the flames.

He attributed his good luck to two mascots—a five-dollar gold piece tied up in a greasy handkerchief and a bit of goldenrod. He refused with a grin to describe the origin of either.

"They worked, didn't they?" was his only comment.

So far as getting first home is concerned the race has been all to the De Haviland bombing planes of the Army Air Service, equipped with 400 horsepower Liberty motors. This by no means establishes supremacy under the peculiar conditions laid down for the present contest. For the first time the American Flying Club has worked out a handicap formula for aeroplanes. Under it victory depends upon the degree with which each machine exceeds or falls below the speed which its horsepower and carrying power should give it.

Flying luck, of course, enters into these calculations and the machines that meet the greatest amount of head winds will suffer for it. Likewise those that ride favoring gales will gain. But, as any entrant could choose his starting point, it all goes to prove the airmanship which will gain the $10,000 of prizes hung up by the Hotel Commodore for the civilians and the commendations for the soldiers who are barred from the money prizes.

The News of the Week

Glidden Plans Two Year Aerial Tour of the World

Atlantic City, N. J.—Captain Charles J. Glidden, donor of the Glidden trophies for automobile and aerial touring, is contemplating a two-year aerial trip around the world. Captain Glidden stated that he intended to cover in one or two years all the points reached in his automobile tour of the world, which required eight years. On the automobile tour the extreme points were the Arctic Circle in Sweden and the most southerly road in the world in New Zealand.

Captain Glidden has driven motor cars in thirty-nine countries, twice around the world, covering a distance of 100,000 miles.

Army Plane Fires on Bandits

Fort Sam Houston, Tex.—An army observation 'plane fired on a group of Mexican bandits on August 19, believed to be the band which captured Lieutenant Peterson and Lieutenant Davis. The following is the official report from Colonel Langhorn:

"Observation 'plane returning here today (August 19) reported having seen three bandits about ten miles west of Candelaria. Bandits fired on 'plane. Fire returned, and aviators believe one horse and one bandit killed, and another bandit took to a nearby canyon, his riderless horse escaping. Both wings of 'plane show bullet holes. LANGHORN."

Three New Landing Fields in Pennsylvania

Harrisburg, Reading and Scranton have each laid plans for the establishment of aerial landing fields. At Harrisburg a committee of business men have been working with the City Council to establish their landing place at the western end of the city. A committee of the Reading Chamber of Commerce, which is consulting with city and county officials, is working out plans for the construction of an aerodrome at a site near the local almshouse. The field is large enough to accommodate one hundred 'planes.

The landing field at Scranton has been officially dedicated by Mayor Alexander Connell. It is pronounced one of the best municipal fields in the locality.

Mr. Claud Johnson, the Managing Director of Rolls-Royce Ltd. who is now in the United States in the interests of his company

Aerial Explorers Over Labrador

Curling, N. F.—Captain Daniel Owen, R. A. F., with a party of aviators who have been making exploration flights over Labrador, returned here on August 22 after a month near Battle Harbor. The expedition was successful in locating timber lands from which millions of cords of pulp wood can be cut and rolled to streams for direct shipment.

The expedition, which included in its equipment three aeroplanes and comprised a personnel of twenty persons, among them five aviators, operated seventy miles north of Battle Harbor. Two million acres of timber land was explored by air and by the ordinary methods of timber cruising. Pictures taken from the air, numbering 13,000, were said to show dense growths of pulp material. This use of the aeroplane was looked upon as opening a new field for commercial aviation.

The planes cruised inland for more than 100 miles, flying at heights of 2,000 to 9,000 feet.

Salesman Gets Large Orders on Speedy Flying Boat Trip

New York, N. Y.—Roland Bassett, chief salesman for Sweet, Orr & Co., overall manufacturers, is the first salesman to employ a flying boat on a selling trip. He flew on August 20 from New York to Poughkeepsie and return, making numerous stops en route. Starting at 1:35 P.M. from West Eighty-third Street, the first stop was made at Yonkers., arriving there at 1:50 P.M., and being tendered a reception by the leading merchants of the town, Mayor Johnson and about 1,000 spectators. The honor of handing the first order to an aerial salesman there fell to George W. Horton, a Yonkers clothing dealer, who handed Bassett a $400 order and suitable congratulations. Leaving there at 2:10 P.M., the next stop, Peekskill, was made in 25 minutes. The first Peekekill order was given by Decatur, Posey & Yellott, dry goods dealers. Newburgh was reached at 3:15. P.M., five minutes ahead of the scheduled time, and there also an informal reception was staged for Bassett. The first order was given by Sig and Max Samuels. Poughkeepsie was reached at 3:56 P.M., by which time the flying boat was ten minutes ahead of the schedule. At this point Bassett and Pilot Zimmermann stepped ashore and after partaking of light refreshment and totalling their orders they purchased newspapers, taking off for New York City at 4:30 P.M. Immediately following there arrival off 33rd Street at 5:35 P.M., the successful air salesman and his pilot were tendered a complimentary dinner by the officers of Sweet, Orr & Company.

Mr. Bassett stated that the flying boat is the ideal means of travel and predicted that it would soon come into general use for traveling men. Lack of suitable landing places was the chief difficulty encountered.

As a result of the success achieved by their pioneer aero salesman, Sweet, Orr & Co. announced that they will place orders for three similar type Aeromarine flying boats.

Aeroplane Hunts Moonshiners

Montgomery, Ala.—Use of aeroplanes in locating illicit distilleries in the Alabama mountains was inaugurated, Deputy Marshal J. A. Wall making a trip over the surrounding territory. He announced later he expected several arrests to follow.

The first test of the Lawson 26 passenger carrier, powered by two Liberty motors took place recently at Lawson Field

Lands and Takes Off from Warehouse Roof

Newark, N. J.—Edwin E. Ballough, of Newark, who was formerly in the Army Air Service, landed an aeroplane on top of a building on August 22 at the Quartermaster's Depot in Newark, and then took off from the roof successfully. This is the first time in the history of aviation that such a feat has been accomplished, although a French aviator once succeeded in landing on a building in Paris. The Frenchman, however, was unable to "take off" from the roof as Ballough did.

Ballough had as a passenger in his machine Chris M. Wagner, a Newark newspaper photographer, and after taking pictures of the depot and the shipyards of the Submarine Boat Corporation, the aviator did stunts for the amusement of the crowd below. He came down to a very low level, and swooped in and out among the boats, several times getting close enough to touch them. Ballough said afterward that the idea of landing on the roof of one of the depot warehouses came to him suddenly and he determined to try it.

He picked out a warehouse 987 feet long and 80 feet wide, with a peaked roof, inclining slightly downward on either side of the peak. The machine spiralled down to a low level and straightened out just above the roof. It then landed successfully, straddling the peak, the greatest danger being the possibility that the machine would go over the edge of the roof sidewise. Ballough stopped the plane about ninety feet from the end of the warehouse, and after resting there some minutes started his motor and "took off" without a great deal of trouble, although after leaving the roof the plane came down so low that it almost grazed the water of the ship canal.

Lieutenant Arthur Brown, Trans-Atlantic Flier, Arrives Here September 20th

New York, N. Y.—Information has been received here that Lieutenant Arthur Whitten Brown, the navigator of the Vickers-Vimy transatlantic aeroplane, will arrive in the United States on September 20. He will make an extensive lecture tour through the United States under the direction of the James B. Pond Lyceum Bureau.

First Lawson Air Liner Completed

Milwaukee, Wis.—The Lawson Air Line Transportation Company of this city has completed the first of its type C-1 passenger carrying aeroplanes, described in detail in the July 7 issue of AERIAL AGE WEEKLY.

The machine is of biplane type, powered by two Liberty engines. The wing spread is 95 feet, length of the body 50 feet, and speed of 90 to 100 miles an hour. According to Alfred W. Lawson, the designer and constructor, one engine has sufficient power to continue flight for 200 miles in case the other engine breaks down.

With a full load of passengers and a large cargo of mail or other material, this machine will climb 4,000 feet in ten minutes. It has a ceiling of 15,000 feet. The gliding angle of this 'plane is so great that it will glide from thirty to forty miles with the engines cut off at 15,000 feet, and the glide angle is so flat that it will not affect the confidence of the passengers, especially those who have never been up before.

Seats are placed at the windows on each side of the cabin, which allows plenty of vision for the passengers, together with a feeling of great security.

It is operated by a captain and two lieutenants, who act as pilots. An engineman and a mechanic are also carried along on the trip as crew in case of need.

Alfred W. Lawson will act as captain of this first ship until one of the two lieutenants has been instructed and is capable of handling the ship in accordance with the new commercial code of flying safely as expected by Mr. Lawson. As soon as pilots prove their capability of safe and sane flying, and new ships are ready for service, the pilots will be promoted to become captains, and will then be given command of ships.

It is the intention of the Lawson Company to build a number of this type of ship within the next few months, to be used in regular daily service between New York and San Francisco, stopping at the leading cities en route.

The new Lawson air liner has already been taken to the Milwaukee County aviation field and is being put thru its initial tests.

Within the next few days it will be started out on a pathfinding tour between Milwaukee, Chicago, New York and San Francisco, and those cities which offer the most suitable landing stations will be selected as the first stations upon the trunk line between the Atlantic and Pacific Oceans.

A few Curtiss Orioles being put through final tests at the Curtiss Field at Buffalo

Ohio Ready to Receive Aerial Tourists

Cleveland, Ohio.—The Cleveland Aviation Club, in response to telegraphic requests to Ohio cities regarding landing facilities for aerial tourists received replies from many cities declaring themselves to be prepared for aerial tourists. These cities include Cincinnati, Youngstown, Urbana, Zanesville, Portsmouth, Mansfield, Findlay, Cambridge, Sandusky and Hamilton.

Although unfavorable weather conditions existed on the opening day of Cleveland Aviation Week, 12,000 people watched a squadron of seven Army planes go through evolutions and stunts over Cleveland Aviation Field. More aeroplanes and a number of balloons will join the squadron before the end of the celebration.

The Cleveland Aviation Club has a membership of which nearly two hundred are Air Service aviators and it is devoting its efforts to making Cleveland a great flying center. This city is on the New York-Chicago and the transcontinental air line.

Air Service Recruiting Discontinued

Washington, D. C.—According to an official statement issued by the War Department News Bureau on August 20, instructions are being issued discontinuing at once enlistments for the heavier-than-air and for the lighter-than-air branches of the air service.

Italian Dirigible to Be Demonstrated in Washington

Washington, D. C.—Lieutenant Signor Angelo Faroli Piazza, R. I. N., will demonstrate the Italian O-9 dirigible to naval officials in the near future. Lieutenant Piazza has received many decorations for his heroism in the war.

Joint Army and Navy Planning Board and Committee Formed

Washington, D. C.—War Department General Order No. 94 provides for the formation and personnel of a Joint Army and Navy Board and a Joint Army and Navy Planning Board. It will have the following membership: (1) For the Army: The Chief of Staff; the Director, Operations Division, General Staff; the Director, War Plans Division, General Staff. (2) For the Navy: The Chief of Naval Operations; the Assistant Chief of Naval Operations; the Director of Plans Division, Naval Operations.

The function of the Board is to secure co-ordination of effort of the two services.

Wadsworth Urges Purchase of Army Air Fields

Washington, D. C.—The purchase of March, Mather, Ream and Ross fields in California; of Ellington, Kelly No. 2, and Brooks Field, Texas; Park Field, Tennessee; Selfridge Field, Michigan; Chanute Field, Illinois; Chapman Field, Florida, and the repair depot at Montgomery, Alabama, is proposed in a bill introduced by Chairman Wadsworth of the Military Committee.

The AIRCRAFT TRADE REVIEW

Duesenberg in New Willys Corporation

New York, N. Y.—Officials of the Duesenberg Motors Corporation announced that it is a subsidiary of the recently formed Willys Corporation, organized to manage the holdings of John N. Willys. The Duesenberg Corporation was formerly a subsidiary of the American Can Company. The new six-cylinder Willys-Overland car is to be constructed at the Duesenberg plant.

Alaska Aircraft Corporation Plans Huge Freight Planes

Seattle, Wash.—The Alaska Aircraft Transportation Co. has been incorporated under the laws of the State of Washington for the purpose of building and operating aeroplanes for carrying passengers and freight. The officers of the company have an intimate knowledge of topographical and climatic conditions in Alaska, as well as of the aircraft and transportation industries.

Flying fields, hangars and shops will be located at Valdez. It is planned to establish landing fields in the interior to replace the present hazardous and uncertain transportation conditions. A machine to carry six tons of freight, having four motors and 3,360 square feet of supporting surface is to be used.

The officers of the company are: Tod M. Date, president and general manager; Milton Van Dyke, first vice-president; H. E. Ellis, second vice-president; James P. Holman, secretary and treasurer. Mr. Tod M. Date, the president of the company, has had twelve years of experience with transportation problems in the North, and was connected with the Standard Aircraft Corporation during the war and the Naval Aircraft Factory at Philadelphia. Associated with him are a group of experts who have been connected with various aircraft companies as designers and constructors.

California-Catalina Service on Six Trips a Day Schedule

San Pedro, Cal.—Syd Chaplin, motion picture star, who has taken up aviation, has inaugurated the first passenger air line in America, which is believed to be the first ever put into daily operation.

Operating between San Pedro, California, and Santa Catalina Island, the Syd-Chaplin Aircraft Corporation is now running a fleet of Curtiss Seagull flying boats on a six-times-a-day schedule, carrying passengers, mail and express. The distance covered is about forty miles and the fare is $27 for one way and for the round trip $43.20. The schedule has been in operation since the middle of July.

The week-end schedule, Friday, Saturday and Sunday, is as follows:

Leave San Pedro.	Leave Avalon..
5:30 A.M.	7:30 A.M.
9:30 A.M.	10:30 A.M.
11:30 A.M.	12:30 P.M.
1:30 P.M.	2:30 P.M.
3:30 P.M.	4:30 P.M.
6:00 P.M.	7:00 P.M.

The midweek schedule, Monday, Tuesday, Wednesday and Thursday, is as follows:

Leave San Pedro.	Leave Avalon.
5:30 A.M.	7:30 A.M.
10:30 A.M.	2:30 P.M.
3:30 P.M.	4:30 P.M.
6:00 P.M.	7:00 P.M.

Mr. Chaplain is the representative for the territory of Southern California and Arizona, and, in addition to passenger-carrying service, he is opening up schools and distributing Curtiss machines, including flying boats and land machines.

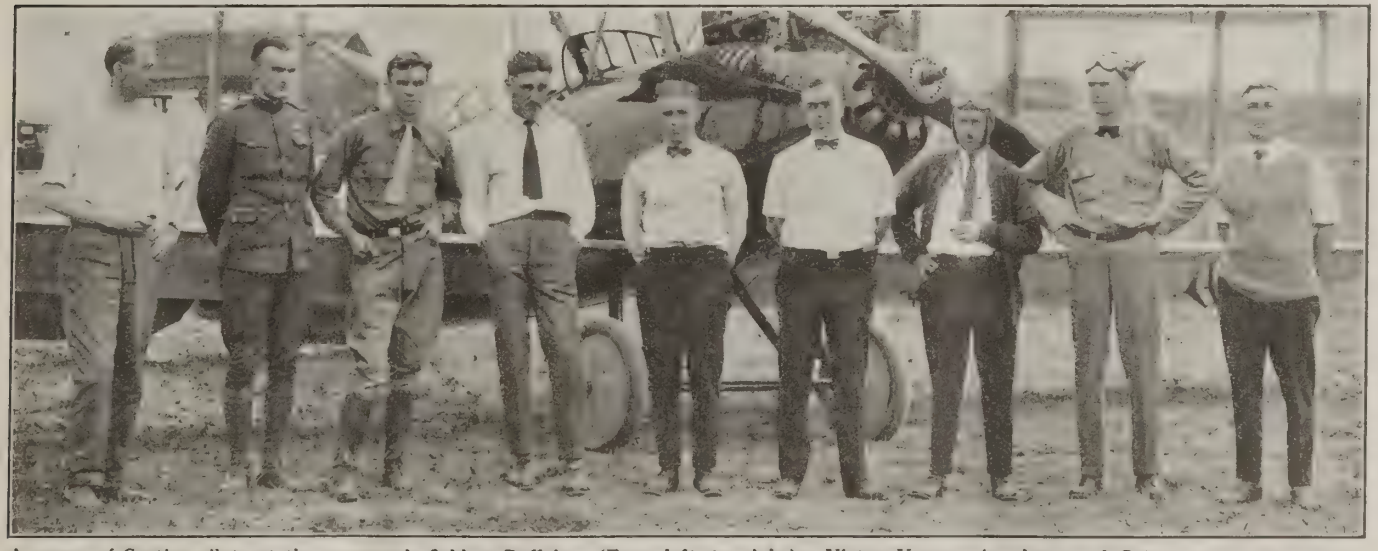
Curtiss Ships Planes to Rio and Buenos Ayres

New York, N. Y.—The first foreign shipment of aeroplanes since the war was made recently, when six land machines of JN type and two Curtiss Seagulls were shipped to Rio de Janeiro. C. W. Webster, in charge of South American sales, sailed on August 23.

Passenger Boards Steamer from Seaplane

Seattle, Wash.—Jasper C. Mayer, a Red Cross official, was forced to miss the steamer Kashimura Maru on July 12, bound for Siberia, on account of delay in obtaining his passports. The ship left at 10:45. At 11:50 Mr. Mayer embarked aboard of Boeing seaplane piloted by Eddie Hubbard. The seaplane taxied alongside the ship and Mayer signalled his associates aboard the steamer. Arrangements were then made to board the steamer by means of the pilot launch.

Although the flight cost $75, Mr. Mayer is well satisfied, having avoided more than two weeks' delay.



Houghton Now With White Company

The George D. White Company, of Los Angeles, has secured the services of Howard D. Houghton, who will take entire charge of their propeller department, according to an announcement made recently.

Mr. Houghton has formerly been with the Glenn L. Martin Company, the Wright-Martin Aircraft Corporation and other leading concerns as well as Government inspector before coming to the White Company. He lately has been with the Loughead Aircraft Company where he designed and constructed the propellers used on the Liberty motored bombing seaplanes built by that firm for the United States Navy. Mr. Houghton's first duties with the White Company will be the construction of the propellers for the giant triple motored monoplane now being built for the trans-Pacific flight.

Wisconsin Aeroplane Firm Building Hangars

Eau Claire, Wisc.—The Eau Claire Aero Corporation has been incorporated wtih a capital stock of $25,000 by local business men. A hangar is being constructed on a new flying field established at the old fair ground south of Eau Claire. Ensign Virgil R. Grace, late of the United States Navy, is vice-president and general manager; Guy R. Wood is president, and A. J. Walsh secretary-treasurer.

A group of Curtiss pilots at the company's field at Buffalo. (From left to right): Victor Vernon, in charge of flying operations; Roland Rohlfs, holder of the world's altitude record; Bert Acosta, pilot; O. S. Parmer, pilot, in charge of aeronautical instruction at Junior Plattsburg Camp; J. P. Davies, sales manager, Curtiss Aeroplane and Motor Corporation; Walter E. Lees, pilot; J. D. Hill, pilot; G. A. Worsham, pilot

Hon. Albert S. Burleson, Postmaster General
Hon. Otto Praeger, Second Assistant Postmaster General
J. B. Corridon, Superintendent, Division of Aerial Mail Service
Louis T. Bussler, Chief of Maintenance and Equipment

J. Clark Edgerton, Chief of Flying Operations
George L. Conner, Chief Clerk, Division of Aerial Mail Service
Eugene J. Scanlon, Chief of Supplies
Charles N. Kight, Special Representative

PILOTS

Dana C. DeHart
Edward V. Gardner
Eber H. Lee
John M. Miller
Leon D. Smith
Max Miller
Charles E. Bradley
Lester F. Bishop
Harold T. Lewis
Leslie E. Stancill
Charles Hugh Anglin
John H. Skoning
Earl F. White
Charles W. Lamborn
Frank H. Crozier
Walter H. Stevens

Charles I. Stanton, Superintendent, Eastern Division
John A. Jordan, Superintendent, Western Division
Harry W. Powers, Manager, Belmont Park
Lowell S. Harding, Manager, Bustleton
Eugene W. Majors, Manager, College Park
W. J. McCandlass, Manager, Cleveland
Ralph D. Barr, Manager, Bryan
O. J. Sproul, Manager, Chicago

Postmaster Sinnott Makes Flight

Postmaster James F. Sinnott, of Newark, N. J., made a flight in a Wittemann-Lewis Model C plane last week, piloted by Lieut. S. A. Morgan, former Army instructor, flying from Newark to Asbury in 29 minutes.

The trip was arranged by L. S. Plaut & Co., of Newark, who makes regular deliveries of their dry goods merchandise by aeroplane. Julius S. Meirick is director of flying at the Plaut plant.

Britain Investigates U. S. Aerial Mail Service

Cleveland.—That the American aerial mail service is attracting international attention is indicated by the receipt of a letter from Winston Spencer Churchill, British air minister, to John A. Jordan, superintendent of the Cleveland-Chicago division, in which the minister seeks all possible data on the system. The letter has been forwarded to Washington.

The letter includes data on British air systems and points out that Great Britain is seeking every possible method to improve and develop aerial travel.

Mail Planes Test Alcohol Fuel

Washington, D. C.—One hundred and thirty gallons of alcohol were brought into Washington by an air mail plane of the Post Office Department recently. The plane flew 3,000 feet over the heads of the excise officers and policemen on the lookout for bootleggers. The alcohol was not carried in the mail bags, which would be in violation of the law, but in the fuel tanks, nor was it peddled around in the haunts of the bootleggers after its arrival. The proper thirst for this character of alcohol has not yet been cultivated. It contains a fair percentage of benzol and enough ether to give it additional kick.

The plane which brings in this alcohol every other day is known among the air mail pilots as the "Bootlegger," and is the forerunner of a revolutionary change in the motor operation of the Air Mail Service. This product is the new alcohol fuel which takes the place of the high-grade aeroplane gasoline. After a number of tests with this new fuel under adverse weather conditions, the Post Office Department is changing over its aeroplane engine attachment and will shortly be operating the entire New York-Washington route with the alcohol fuel.

Its great advantage lies in the cleanliness of the motor, reducing cost of upkeep, and in its burning cooler than gasoline, thereby overcoming objections to the high compression motor at low altitudes. The planes which ordinarily use 25 to 26 gallons of gasoline operate on the new fuel on about 20 gallons, which gives greater flying radius to the planes. It reduces chances of forced landings by keeping the spark plugs and the engine cylinders clean of carbon and oil accumulations. With this fuel it will be possible to operate the mail in a De Haviland 4 regularly in a non-stop flight from New York to Cleveland, a distance of 430 miles, whenever fog or rain conditions in the mountains make it inadvisable to attempt to land at the intermediate field at Bellefonte, Pa.

Oriole Flies from Denver to Estes Park

Denver, Col.—Seventy-nine years after the first white man, Kit Carson, entered Estes Park, Colorado, and sixteen years after the first auto made its appearance at the same spot, a Curtiss Oriole three-passenger land machine recently made a successful flight from Denver to the famous Colorado resort. Against a heavy wind blowing off the Continental Divide, the 'plane, carrying a special aeroplane edition of the Denver *Post*, made the trip in fifty-five minutes. In addition to several hundred copies of the paper, the machine carried I. B. Humphreys, president of the Curtiss-Humphreys Airplane Company, and Pilot A. M. Lendrum, and reached an altitude of 11,940 feet.

Personal Pars

Lieutenant Leon B. Wilcox, chief engineer officer at Chanute Field, has received his discharge and has been made chief motor instructor at the Academy of Applied Aeronautics, Chicago, Ill.

"NEW PLANES FOR OLD"

THE WORK OF THE AVIATION REPAIR DEPOTS

By WILLIAM MENKEL

Former Captain in the U. S. Air Service and Commanding Officer of the Aviation Repair Depot at the Speedway, Indianapolis, Ind.

The Aviation Repair Depot at Indianapolis has been so thoroughly co-ordinated and systematized that AERIAL AGE *has found it desirable to describe the entire system of the depot, and has been fortunate in securing the co-operation of Capt. Menkel in this work, under whose command much of the good work at Indianapolis was accomplished. In the forthcoming days of commercial aerial transportation, when every large efficient aircraft corporation will require an efficient repair depot, the present article may well be taken as a substantial "standard practice" when outlining such a factory.*—EDITOR.

THAT the Air Service program mapped out for war purposes was elaborate and expensive is well known, and much has been written in the public press and aired in Congressional speeches regarding the immense outlay of American treasure, all having for its final and dramatic object the defeat of the Boche by air. Yet few people realize the manifold ramifications of our aeronautic activities—the various ground schools, training fields, repair and supply depots, radio, photographic, gunnery and balloon schools, mobilization camps, testing field and acceptance park, and a multitude of other institutions that sprang up almost like mushrooms in the night, dotting the country from coast to coast and from North to South. A map of all the air service stations in this country alone, to say nothing of American stations located in Canada, England, France and Egypt, would be an "eye-opener" to the average individual who was curious to learn the ultimate destination of the hundreds of millions appropriated for American aviation.

There was little opportunity for the public to know of many of these war plants of the air service, except for the people in the immediate vicinity. The flyers at the front naturally were principally in the public eye. That was the spectacular work that caught the imagination and was made much of in the war reports; and over here the various flying fields frequently got into the newspapers by reason of the occasional accidents that happened to the students in training as pilots. In other words, the outside public had occasion through the press to become acquainted only with the air service work above ground—the things pertaining to actual flying—but of the busy institutions manned by the "ground aviators," the foundation for the actual flying, and all the other activities that kept the boys in the air—these were matters that were seldom written about.

Nevertheless, behind the heroic plane fighter over the lines was a series of important factors too numerous to mention, not the least vital of which was the training field back in the States or elsewhere, where the aviator did his first "solo," probably broke several landing gears or a propeller or two, or perhaps even suffered a "crash" before he got his coveted "wings." If he was fortunate enough to escape such mishaps himself, it is almost certain that during his training novitiate he witnessed more than one smash-up, and even if the pilot in the case was not badly injured, the ruined plane must have struck his vision as a hopeless wreck and worthless for anything but the junk pile.

Function of the Repair Depots

But there is where one of those numerous air service institutions, little known to the public at large, came to the rescue. For the hopeless-looking wreck was carefully gathered up, after proper official report of the accident, and the plane duly "surveyed" by an officer—which is what happens to Government property when it becomes unfit for use—and the whole mess boxed up and shipped to the nearest aviation repair depot, to emerge soon

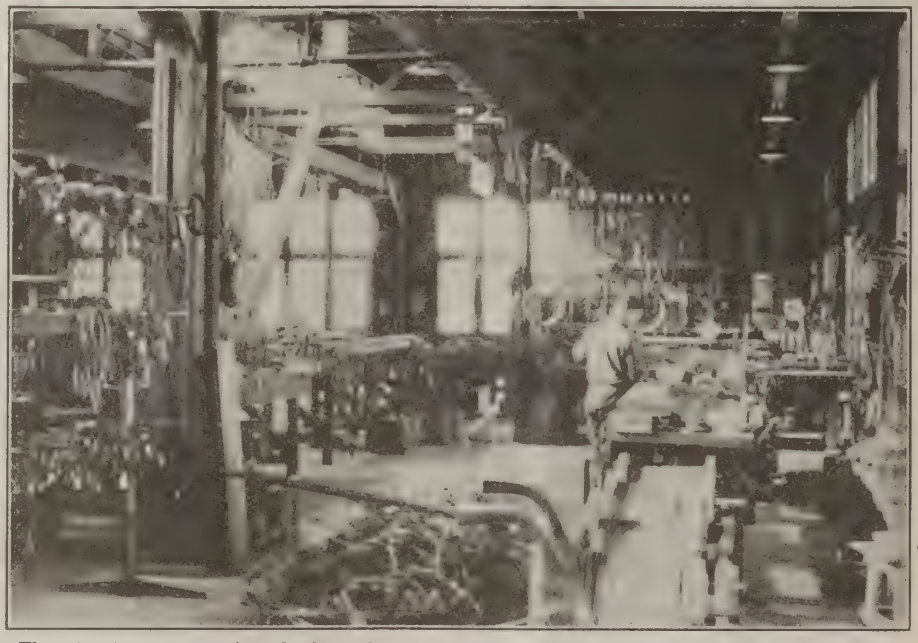
AN AERIAL VIEW OF THE AVIATION REPAIR DEPOT AT INDIANAPOLIS

In the center left hand corner of the picture is the building occupied by the Pomillio Bros. Aviation Experimental Works. In the upper left-hand corner is a portion of the Prest-O-Lite Factory. On the right hand side of the road running through the center of this group of depot buildings are the Administration Headquarters, the Quartermaster and Aero Supply Buildings, and the shops, the two larger buildings in the background being the Engine Repair Building and the Aero Assembly. On the left of the road are the various barracks and mess halls for the men, with the Y. M. C. A. Building and Guardhouse in the foreground. In the lower portion of the picture can be seen the open air boxing ring and basketball courts located at one end of the baseball field

afterward as an apparently brand-new spick and span machine, ready again for the air. Of course, it may not have been entirely the same plane. It might well be that it had been so badly damaged that nothing remained of the original machine but the number on the fuselage, which was always scrupulously retained even if everything else had to go by the board. But obviously the damage inflicted on planes at the flying fields was not always so great. It varied from a slight injury to the engine, or a broken strut or wire (which was remedied right at the field), to the partial or total wreck that made the machine a subject for the repair depot "hospital."

And with the wreck written off the account of the flying field and duly shipped off, it was up to the repair depot to make good, to send out in its place a perfect plane, with shining doped wings and bright new Air Service Bull's-eye, thus not only saving Uncle Sam millions of dollars by the salvaging of junk and the repair of broken machines, but also helping to maintain the supply of training planes for the thousands of fledgling pilots eager to master the air.

Turning out stick controls in the wood working department



Important Improvements Devised in planes

But it was not merely in the routine repair work that these depots distinguished themselves. To them is due also the credit for making ingenious innovations in construction, resulting in greater safety for the pilot and increased efficiency of the plane. For instance, it was noticed at the Indianapolis depot that many a machine that came in for repair had the curved edge of the cowl dented where the head of the pilot had struck as the machine crashed. It was thereupon decided to cut out a semi-circular section of this cowl frame, thus making it more unlikely that the pilot's head should strike that section in a smash-up. The same thing was true of many of the instrument boards. They were so near the pilot that in a crash his head was likely to smash against it. One board, in fact, that came into the instrument room for repair showed the glass of the altimeter smashed and smeared with blood where the pilot's head had crashed into it. The instrument boards were thereafter accordingly set further away from the pilot's seat, giving him more clearance, so that as long as the safety belt held him in, his head was less likely to knock against the instrument board in front. Another important improvement showing the value of the close study given to the wrecks at this depot was the reinforcing of the longerons of the front cockpit. It was observed that in the majority of planes that had suffered head-on crashes the engine had telescoped into the cockpit. It is this kind of thing which accounts for the fact that the front-seat passenger in a head-on crash is usually the most injured, often fatally. The brace section of the longerons was therefore strongly reinforced on each side of the front cockpit, thus lessening the danger of the complete telescoping of the fore part of the fuselage, and greatly diminishing the chances of fatal injury to the occupant.

Locating the Depots

How the repair depots did all this work is one of the interesting phases of our war aeronautics. The repair depots in this country were only three in number, but they were strategically located with relation to the flying fields, and they proved themselves fully adequate to rehabilitate the planes that the boys smashed up. Although our thirty-six flying fields in the United States were scattered all over the country, there were three main groups, geographically speaking. Texas had the greatest number, with its famous Kelly Fields (numbered One and Two), Brooks Field, Post, Call, Love and Rich Fields; and so one of the repair depots was conveniently located at Dallas. Eberts Field in Arkansas, Park Field in Tennessee, Gerstner in Louisiana and the Mississippi and Florida fields were served by the repair depot at Montgomery, Alabama. Up in the northern and central parts of the Middle West were Selfridge Field at Mt. Clemens, Michigan; Scott Field at Belleville, Illinois; Chanute Field at Rantoul, Illinois; McCook and Wilbur Wright Fields at Dayton, Ohio, and Payne Field at West Point, Kentucky. This group necessitated another repair depot for their requirements, and this depot was logically and wisely placed at Indianapolis. In addition to being centrally located with reference to the flying fields to be served, the important elements in securing a good location for a depot of this kind were accessibility to sources of supplies and good shipping facilities. The Indianapolis depot was especially fortunate in these regards, for the Hoosier capital is a converging point for many railroad lines, two of which have switches running right out to the shops of the repair depot, while the market in this vicinity for tools, machinery and other supplies is exceptionally good.

The great centers of the automobile industry are only a few hours' ride distant. Raw materials like steel, lumber, and aluminum are readily obtained, and spare parts and miscellaneous supplies are within easy reach. Not only are machine manufacturers scattered all over Indiana, with the large cities in adjacent States only a jump away, but right in the city of Indianapolis itself are many motor factories, machinery, tool and hardware

The wire department where broken wires are replaced and turnbuckles are adjusted. Roebling Co.'s wire is much in evidence here, as are also the turnbuckles of the Dayton Metal Products Co., Dayton, Ohio

dealers. These concerns supplied much of the equipment of the Aviation Repair Depot located at the famous International Motor Speedway, and on innumerable occasions the proximity of these concerns rendered it possible to obtain immediately tools and other supplies on emergency orders, saving days and weeks of time that would have elapsed in getting material from a distance. This meant that jobs were seldom held up for want of needed material.

The plant is located about six miles out from Indianapolis, not far from the motor race track, the inside field of which is used by the Repair Depot as a flying field. Here planes that come for overhauling, and visiting aviators, land; and here also the repaired planes destined for fields in the immediately surrounding States are assembled, tested by civilian aviators employed for the purpose, and flown away. The Motor Speedway is used in this manner through the courtesy of Messrs. Carl G. Fisher and James A. Allison, of the Speedway Corporation, which also erected two hangars on the field and placed them at the disposal of the Government. The Repair Depot grounds occupy about twenty acres adjoining the Prest-o-Lite factory and the plant of the Pomillio Bros. Aviation Experimental Works. Construction was begun in November, 1917. The score or more of buildings of the depot represent an outlay of $650,000; the machinery and equipment were installed at a cost of $84,803.25. With leasehold rights and improvements, the total value of the plant approximates $800,000, and, including the stock on hand, the value of the entire depot in buildings, property and equipment exceeds $1,500,000.

Major Patrick Frissell, J. M. A., Commanding Officer, Aviation Repair Depot, Indianapolis

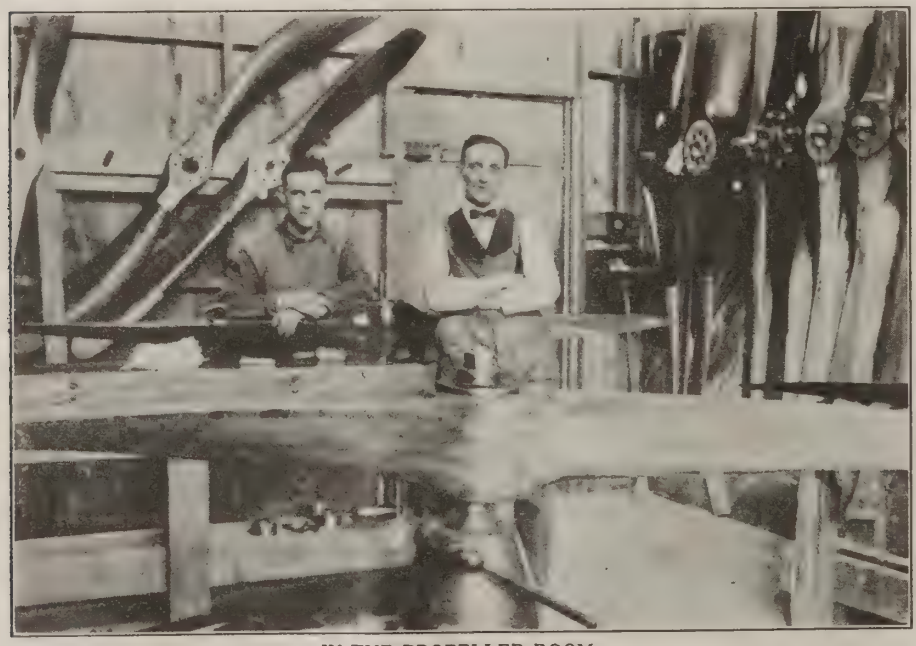
Fire protection naturally had to be of the best, not merely on account of the value of the equipment in the shops, but because the destruction of the plant during the war would have meant a serious delay in time required to replace it. The overhead sprinkler system of the International Sprinkler Company of Philadelphia was therefore installed, while numerous hand fire extinguishers were scattered plentifully throughout the shops, from the small Fyr-Fyter type to the larger Stempel Army Fire Extinguishers, and also the Badger Company's product.

The mechanical equipment of the three aviation repair depots is practically the same, for the same kind of work, so that

INTERIOR OF THE DOPE HOUSE

Where thousands of gallons of Dupont Dope and Sherwin Williams' Paints and Varnishes have been used

An aeroplane wreck showing the condition in which they sometimes come to the repair depot



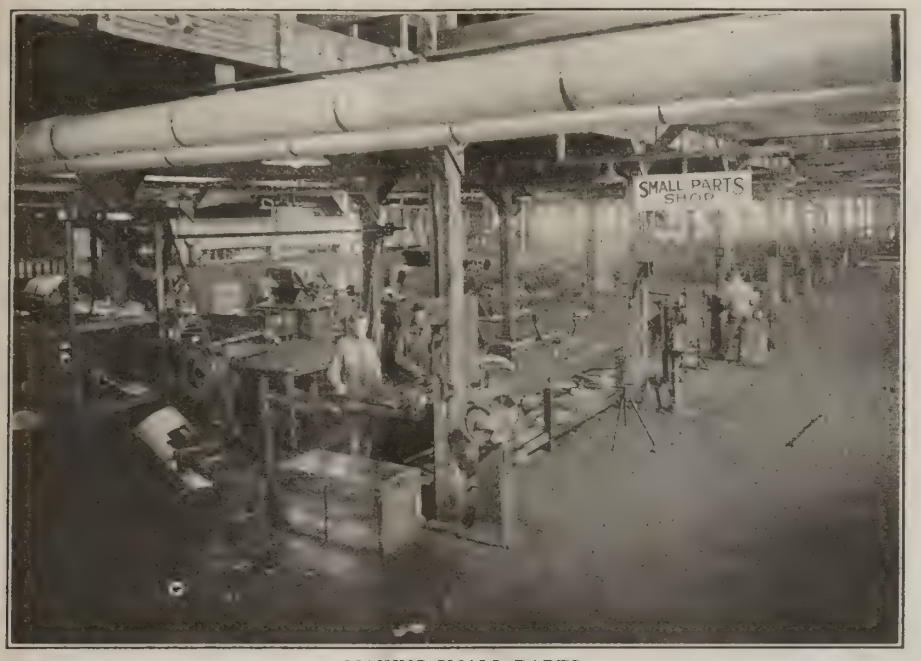
THE WOOD WORKING DEPARTMENT

In this well-equipped shop can be manufactured every wood part of an aeroplane except the propeller. The equipment includes a drill press, boring machine and cross cut saw, all from the J. A. Fay & Egan Company, Cincinnati; jig saw, wood lathe, shaper, plane surfacer, grind stone and saw, from the American Wood Working Machine Company, Williamsport, Pa.; band saw, Crescent Machine Company, Leetonia, Ohio; emery wheel, Hisey-Wolf Machine Company, Cincinnati; oil stone grinder, Mummert-Dixon Company, Hanover, Pa.; vises and files for filing and setting saws, Machinery Company of America, Grand Rapids, Michigan; wood machinery, Frank K. Moore, Boston; belt sander and cross cut saw, Oliver Machinery Company, Grand Rapids; rip saw and 24" planer, J. T. Townsley Company, Cincinnati; self feeding rip saw, Sinker-Davis Company, Indianapolis, and an Eaglesfield 6" molder, Vonnegut Machinery Co., Indianapolis. Westinghouse motors are also used for driving the machinery and a plentiful supply of LePage's Glue is found on the benches in this shop. The lumber comes from the Johnson Lumber Co., of Indianapolis

the Indianapolis depot may be taken as typical in this regard. The machines and tools were selected by Army aviation officers of exceptional engineering experience, and represent the result of their expert knowledge of the entire machinery field, and the requirements of aeroplane construction and engine repair. Responsibility for the proper equipment of the shops and the efficient training of the personnel fell on the shoulders of the first commanding officer, Major (now Lieutenant-Colonel) Guy L. Gearhart, and Captain Edward Laughlin, who was the chief engineer officer.

The plant management system was organized on a basis of practical up-to-date efficiency. The best shop methods in America were studied. Unnecessary routine and paper work were abolished, and red tape was not allowed to stand in the way of securing a needed bolt or screw or other supplies. No job was held up for lack of material. Supplies were obtained without delay from the nearest stockroom. The tool room was placed in the center of each shop, making a trip to it of equal distance for all the workers, and the brass check system adopted for checking out tools. The time clock was applied both to the men and the particular job which was going through the shop. Dealers in supplies were card indexed and their promptness in making deliveries recorded. Delays were noted against the offenders and future orders given to the prompt ones. Shop and work forms were devised after careful study and adopted for use in connection with each job and all shop routine. These forms include the "Dismantling Record," "Dismantling Report," "Assembly Report," separate inspection reports for fuselage, wings, ailerons, landing gear, propellers; production and cost records, "Motor Test Sheet," time tickets for jobs, stock room requisitions, work orders, daily return for each department showing work done, "Receiving Report," "Transfer of Materials," and different colored tags showing parts "O. K. for Service," "Condemned" and "To Be Repaired." There are also time cards for the men and "Records of Transfer" for use when the worker is detailed from one department to another. In addition to all these, there is a large manila folder with a comprehensive form printed on it, which is used for a complete "Repair Record and Cost," and on which is noted all the data relating to the history of a job from its receipt to delivery.

IN THE PROPELLER ROOM



A propeller is seen on the balance stand (Rockford Tool Company, Rockford, Ill.), and other equipment includes a propeller vise (J. A. Fay & Egan Company, Cincinnati), and a bench planer (J. D. Wallace Company, Chicago). The Star Piano Company, of Chicago, has been furnishing propellers

Record of Production

The Indianapolis Depot was the first of the repair institutions to be equipped and get under way into actual production. The initial wreck arrived in April, 1918. At first progress was slow and gradual, due to the lack of the necessary blue prints, specifications, etc., and to the need for instructing the raw "ground aviators" in their new work. Very soon, however, a rate of a plane and an engine a day was reached, which was the estimated output on which the plant was built. Not long afterward, however, this depot adopted and lived up to the slogan of "Three a Day," actually turning out onto the shipping platform three engines and three aeroplanes in each working day. Although at times the wrecks only trickled in one by one, there were other occasions when they came in flocks—as, for instance, after the disastrous hurricane at Gerstner Field, Lake Charles, Louisiana, last year, when one hundred of the broken planes from that point were received at the Speedway Depot; and some months later sixty DeHavilands recovered from the sunken *Americus* were sent here for salvaging.

Up to the end of 1918 planes to the number of three hundred and thirteen had been repaired at the Speedway, with a valuation of $1,195,550; and 350 aeroplane motors with an approximate value of $638,699. Also $300,000 worth of wings, ailerons, elevators, rudders, stabilizers, struts, and miscellaneous fittings had been turned out. The entire value of aeroplanes, motors and parts repaired at this depot up to January 1, 1919, exceeded $2,130,000. Since the signing of the armistice the work has naturally slowed down somewhat, due both to the lessening of the incoming wrecks and to the partial demobilization of the soldier workmen. The total of planes produced up to March 3, 1919, however, was 352 and the engine total was 371.

The Montgomery, Alabama, Depot was not completed until July 1st, 1918. In its eight months of operation up to March 1,

MAKING SMALL PARTS

The Small Parts and Welding Department is equipped to fashion any of the great variety of the small metal fittings that go into aeroplane construction, and also some larger ones like engine hoods. This work requires, among other things, a rotary shear (Otis Fuller, Goshen, Indiana), a casting form for engine hoods (Hetherington Burners, Indianapolis), solder furnaces (Superior Solder Furnace Company, Warren, Pa.),feeding and turning machines, metal roller, mandrel, 30" square shear, eight foot and four foot brakes, all from the Peck, Stow & Wilcox Company, Cleveland; splitting shear (Niagara M. & T. Works, Buffalo), pattern filing machine (Oliver Instrument Company, Adrian, Mich.), bench and mandrel presses (Atlas Company, Kalamazoo), drill press (Patterson Tool & Supply Company, Dayton, Ohio), bench shear (Vonnegut Company, Indianapolis), a gang punch and bench shear, from the Badger State Machinery Company, Jamesville, Wis.; emery stand (U. S. Electrical Tool Company, Cincinnati), and a Gray's Sheet Metal Cutter (W. J. Savage Company, Knoxville, Tenn.). The sheet metal is supplied by the Langencamp Co., of Indianapolis

1919, this Depot turned out 155 planes and 187 engines.

Most of the repair work has been on the Curtiss types, the J. N. 4D and the J. N. 4H, with Curtiss O. X. 5 and Hispano-Suiza motors; also Curtiss planes with gun equipment, and some with photographic equipment. A number of De-Haviland planes have also gone through the shops. Various other types, such as Thomas-Morse, and some "hybrids" and obsolete machines of one kind or another have at different times found their way into the depot. Earlier in the history of the plant Standards were also worked on, and one of the big Handley-Page machines is now awaiting repair at the hands of a competent force of aeroplane mechanics. The training of these mechanics was in itself a notable achievement. The Indianapolis personnel consisted of some thirty officers and four aviation repair squadrons, the 809th, 810th, 811th and 821st (150 men each), with medical and quartermaster detachments in addition. Three of the squadrons came from the big air service mobilization camp at Kelly Fields, Texas, and the fourth was recruited from Indianapolis and the vicinity. About four hundred and fifty of the six hundred squadron men were gradually absorbed into the shops, and these, together with thirty-two civilian employes, made up the working force. The soldier workmen, although belonging to aviation repair squadrons, were by no means expert aeroplane mechanics when they arrived.

A CORNER IN THE INSPECTION DEPARTMENT

This department makes use of many instruments for exact and minute measuring and gauging, such as micrometers and calipers manufactured by the Brown-Sharpe Company, Providence, R. I.; the Scleroscope for testing the hardness of metals (Shore Instrument & Mfg. Co., N. Y.), as well as ordinary small Buffalo Scale Company's weighing scales. Some of the micrometers are also furnished by the L. S. Starrett Company, Athol, Mass.

Making Aeroplane Mechanicians

How Uncle Sam secured a competent body of aviation shop workers is an interesting story in itself. In fact, one of the remarkable achievements of the American Air Service has been the enlisting and inducting of a large mass of miscellaneous civilian mechanics, the vast majority of whom had never had anything to do with aeroplanes before, and turning them in a few short months into expert aeroplane workers. Outside of the privately owned aircraft factories, aeroplane mechanicians were practically nonexistent. The trade had not assumed a standard and recognized place in our industrial life. With the entrance of the United States into the war and the planning of the great air program the country was combed for mechanics and tradesmen of all kinds whose experience rendered them valuable in the construction of various parts of an aeroplane. These included automobile body builders, motor mechanics, blacksmiths, carpenters and cabinet makers, chauffeurs and garage men, metal workers, welders, draftsmen, electricians, tailors and sailmakers, watchmakers and instrument workers, painters, plumbers, and a variety of other kinds of tradesmen, as well as the necessary number of clerks and cooks.

To train these men and adjust their skill to the repair and manufacture of aeroplanes was the immediate task of the Government Air Service. A good deal was accomplished by the establishment of enlisted mechanics' training schools, where the men were given short intensive courses in aeroplane engines, wing and fuselage construction, as well as in aeroplane nomenclature. These men were formed into repair squadrons and shipped to various points for duty or further training. The squadrons which came to the Indianapolis Depot were carefully trade-tested to record their experience and skill in certain lines, and were then put to work at the jobs best suited to them in the repair shops. These shops had their several departments devoted to all the various kinds of aeroplane work. Automobile motor men quickly learned the construction and operation of aeroplane engines; carpenters and cabinetmakers were shown how to apply their skill to the making of longerons, struts, skids, wing sections, and other wood portions of the aeroplane; metal workers learned how to fashion the small metal parts, tailors were taught how to sew the linen on the wings, painters were quick to learn the knack of applying dope varnish to the finished wings and the body of the plane, and so on. Enlisted men of various trades were thus utilized, each for work in his own line, in repairing and rebuilding machines with which they had had no previous experience. Under careful instruction and supervision this body of green aeroplane mechanicians developed into expert workers, producing for this one depot alone a daily output of engines and aeroplanes that would have

THE AERIAL CARNIVAL AT FORT OMAHA

AN aerial carnival was held at the Fort Omaha Balloon School on July 13 for the purpose of stimulating recruiting in the balloon section of the Air Service.

The main events of the day was the balloon race, of which a summary follows:

Balloon No. 2, "All America," First Lieut. Richard E. Thompson, pilot; Second Lieut. James B. Jordan, aide; left at 8:52 P.M., 13th. Landed 9 miles southeast of Portage, Wis., 1:45 P.M., 14th. Maximum altitude, 12,500 feet. Time in air 16 hours and 53 minutes. Distance traveled 409 miles. First place.

Balloon No. 1, "United States," Captain Ashley C. McKinley, pilot; Second Lieut. James T. Neely, aide; left at 8:58 P.M., 13th. Landed 6 miles south by west of Rowley, Iowa, at 12:01 P. M., 14th. Maximum altitude 9,000 feet. Time in air, 16 hours and 3 minutes. Distance traveled, 136 miles. Second place.

Balloon No. 3, "Victory," Second Lieut. William E. Huffman, pilot; Second Lieut. William E. Connelly, aide; left at 8:55 P.M., 13th. Landed at 1:20 P.M., 14th. Maximum altitude 7,200 feet. Time in air, 16 hours and 25 minutes. Distance traveled, 211 miles. Third place.

Balloon No. 4, "Cannon Ball," Mr. A. Lee Stevens, pilot; Lieut. Col. Jacob W. S. Wuest and Major Martin J. O'Brien, aides; left at 9:03 P.M., 13th. Landed four miles south of Ringstead, Iowa, 3:48 A.M., 14th. Maximum altitude 6,600 feet. Time in air, 6 hours and 45 minutes. Distance traveled, 158 miles. This balloon contained the judges for the race.

Balloon No. 4, "Cannon Ball," entered terrific thunderstorm at 2:10 A.M. Encountered cyclonic winds over Minnesota Lakes and forced southeast, and finally beaten to the ground at 3:48 A.M.

Other balloons encountered same storms, but were apparently at their outer edge, so continued the race.

Balloon No. 2, "All America," won a silver loving cup and the pilot and aide were awarded gold wrist watches donated by the Omaha Chamber of Commerce and the Board of Governors of the Ak-Sar-Ben Club of Omaha.

Balloon No. 1, "United States," and Balloon No. 3, "Victory," won second and third prizes, respectively, consisting of silver cirgarette cases appropriately engraved for the pilots and aides.

The prizes were presented in person by Colonel C. De Forrest Chandler, chief of the Balloon and Airship Branch, Air Service, at Fort Omaha, on July 22, 1919.

Lieut. Colonel Jacob W. S. Wuest, J.M.A., A.S., M.A., commanding officer, presided at the ceremonies.

The hearty co-operation accorded it by the officers and men of the post and by the leading business men of the city of Omaha insured the overwhelming success of the carnival.

The official announcer at the Aerial Carnival at the Fort Ohama Balloon School was suspended 100 feet in the air from a captive balloon

Due to efficient organization the various committees performed their plans without hitch. The scope of their activities may be judged by the following list showing their organization and membership:

Commanding Officer—Lieut. Colonel Jacob W. S. Wuest.

Adjutant—Major Martin J. O'Brien.

Director of the Carnival—Mr. A. Leo Stevens.

Grounds and Property—Major R. T. Crawford, Second Lieut. R. S. Hall. (a) Decorations—Captain C. R. Jacobson, Second Lieut. W. E. Connolly. (b) Construction—First Lieuts. W. C. Burns and H. C. MacNeill. (c) Reception and Entertainment—Captain A. C. McKinley, Captain S. L. Dowd.

Balloons—Second Lieuts. R. A. Reynolds, W. E. Huffman, R. Robertson.

Athletics—Second Lieuts. J. O. Tooley and Mr. D. J. Ryan.

Transportation and Traffic—Captain C. F. Adams, Second Lieut. R. P. Clapp.

Refreshment and Concessions—Second Lieuts. G. G. Lundberg, R. G. Conklin and J. B. Jordan.

Publicity—Major M. J. O'Brien, Second Lieut. J. T. Neely, Mr. A. Leo Stevens.

Recruiting—First Lieuts. R. E. Thompson, J. M. Riggs.

Contests and Records—Second Lieuts. C. L. Meisinger, A. H. Foster.

Police and Fire Protection—Captain H. T. Lewis.

Program—First Lieut. H. C. MacNeill, Second Lieuts. J. T. Neely, G. G. Lundberg, W. E. Connolly and Mr. A. Leo Stevens.

Athletic Events—Starter, Second Lieut. J. O. Tooley; judges, Second Lieuts. J. R. Hall, H. S. Froehlich and Mr. D. J. Ryan.

It is estimated that over 25,000 people witnessed the carnival, and all the events went off smoothly and according to the program, in spite of the high winds.

An added attraction was the appearance of two aeroplanes from the hangars of the Omaha Flying Company, which circled the field and took pictures of the events from the air. Moving pictures were obtained of the officers who participated in the flying events and of a parachute drop. These pictures were all displayed at local theaters throughout the following week, the audiences showing intense interest in them and applauding heartily.

---

600 Mile Balloon Flight

Post Field, Fort Sill, Okla.—Pilot Lieutenant Hoke S. O'Kelly, with Lieutenants Carlton F. Bond and William H. McIlwain, and Sergeants Louis N. Morris and Edwin Schneider as passengers in a 35,000 cubic feet free balloon, made a flight from Post Field to Lexington, Neb., 600 miles, in 31 hours. Maximum altitude 5,400 feet. Five landings made en route.

From left to right, Cacquot observation balloon, German Drachen, nurse balloon, Italian A. P. observation balloon. The small balloons in the air are propaganda balloons

TESTS ON THIN PLYWOOD AS A SUBSTITUTE FOR LINEN IN AEROPLANE CONSTRUCTION

By ARMIN ELMENDORF*

THE use of thin sheets of wood properly glued together in place of linen for aeroplane covering has long been considered as a possibility. Veneer of some species may be cut into large sheets only 1/150 inch thick. When three sheets of such thin material are glued together, a covering is obtained whose weight compares quite favorably with that of doped aeroplane linen, so that there is some reason for considering wood as a material for covering, although at first thought it might seem to be out of the question on account of its apparent excess weight.

In view of the frequent demand for information upon the properties of thin plywood and its uses in aeroplane construction, tests were initiated at the Forest Products Laboratories of the U. S. Forest Service, at Madison, Wis., to determine the merits of thin plywood as a covering for aeroplane surfaces. While it was possible to prepare very thin sheets of three-ply wood that would be as light as doped linen, a few attempts at gluing such material soon showed that the difficulty of handling the veneer made the manufacture of plywood of this kind impractical, at least in the present stage of the plywood industry. A few tests also showed that very thin plywood lacked toughness and tearing strength, and there seemed to be little hope of using the lightest plywood. The tests were, therefore continued on somewhat thicker material with the surmise that the heavier plywood might possess other properties that would compensate for its excess weight.

* Engineer in Forest Products, Forest Products Laboratory, U. S. Forest Service, Madison, Wis.

Figure 1

Method of measuring the toughness of thin plywood sheets by dropping a 3.27 pound iron ball upon the center of the test specimen

Figure 3

Measurement of rigidity by the magnitude of the load on a given deflection, determined by sand load test

The relative importance of the various properties desired in an aeroplane covering is not established. Each of the following properties is, however, of sufficient consequence to merit consideration: (a) Minimum weight consistent with safety; (b) high tensile strength; (c) high toughness, or resistance to blows tending to rupture the covering; (d) high tearing strength; (e) high rigidity, or minimum stretch under load; (f) maximum stability; (g) resistance to fire.

Tests made by many experimenters with the use of a variety of chemicals have shown that wood may be impregnated with solutions that render it highly fire-resistent; consequently, no special work was undertaken to treat thin plywood for this purpose.

Tests were devised to measure the quality of the material in each of the other properties mentioned above, and the results, obtained from more than two thousand such tests, are here briefly considered.

Practically all the material tested was glued at the Laboratory by the tissue process, in which a sheet of tissue, previously soaked in blood-albumin glue and dried, is inserted between two sheets of thin veneer and then pressed in a hot press to set the glue.

Among the species that may be cut into very thin veneer are Spanish cedar, mahogany, birch, sugar maple, red gum, yellow poplar, and black walnut. The veneer of these species may be satisfactorily glued by the tissue method.

Three constructios of thin plywood were prepared: First, a three-ply construction in which the grain of the center ply was at right angles to the grain of the face plies; second, a construction in which a piece of cloth was incorporated between two veneer plies having their grains at right angles; third, a construction in which a piece of cloth was glued between two plies of veneer, whose grains made an angle of 60 degrees with each other.

Weight

The weight of aeroplane linen given five coats of dope at the Laboratory was about 0.9 ounce per square foot, while the minimum weight of three-ply Spanish cedar made of 1/150-inch veneer was about 1 ounce per square foot. Thin plywood constructions that were considered satisfactory from the point of view of facility of manufacture and with respect to strength and toughness weighed slightly more than 2 ounces per square foot. In constructions of this kind a

sheet of cotton cloth was glued between two sheets of this veneer, the thickness of the veneer used being about 1/60 inch for low-density species, such as basswood, Spanish cedar, and yellow poplar. For high-density species, such as birch, beech, and sugar maple, a veneer thickness of about 1/80 inch gives a plywood weight of from 2 to 2.5 ounces per square foot. A large part of the weight of thin plywood lies in the glue.

Tensile Strength

Strips one inch wide were tested in tension, their ends being held between flat grips, in an ordinary Olsen testing machine calibrated to read to one pound. In the case of three-ply wood, tension tests were made both in the direction of the face grain and in the direction of the core grain. In two-ply construction, where the plies were glued so that the grain of one face was at right angles to the grain of the other face, the tests were made parallel to the direction of the grain of each face. In two-ply construction, where there was an angle of 60 degrees between the directions of grain in the face plies, the plywood was tested in the two directions bisecting the angles between the grains of the faces.

A two-ply construction in which the grain of one ply makes 90 degrees with the grain of the other ply should have the same tensile strength in the direction of the grain of each face, which is practically equal to that of the single ply of veneer. The tensile strength of birch veneer is about 20,000 pounds per square inch at 8 per cent moisture. From this it is seen that the strength of a straight-grained ply 1/80 inch thick should be about 250 pounds per inch of width, which is more than three times as great as the strength requirements of Grade A aeroplane linen. The two-ply, 90-degree construction described gave entirely satisfactory tensile strength. The two-ply, 60-degree construction gave relatively low tensile strength. It was stronger in the direction of the grain of the veneer than in the direction in which the tests were made.

Toughness

In addition to being strong in resisting a tensile load slowly applied, aeroplane covering must also offer resistance to sudden blows, such as would result from striking brush on landing or dropping tools while assembling or repairing the machine. The method used by the Laboratory for measuring the toughness of thin plywood sheets is shown in Figure 1. A cast-iron ball weighing 3.27 pounds is dropped upon the center of the test specimen, which is tacked upon a frame 18 inches square inside. The ball is dropped upon the center of the panel from various heights, beginning with a ½-inch drop and increasing by ½-inch increments. The height of the drop at which the ball passed through the panel was recorded as the measure of toughness.

The tests showed conclusively that very thin three-ply wood, such as that made of Spanish cedar veneer 1/150 inch thick, is low in toughness, and for that reason is not satisfactory as a substitute for linen. In order to improve the toughness of thin plywood made of veneer thinner than about 1/50 inch, it was found necessary to incorporate a cloth fabric between the plies. Aeroplane cotton, Grade A, proved to be very satisfactory for this purpose.

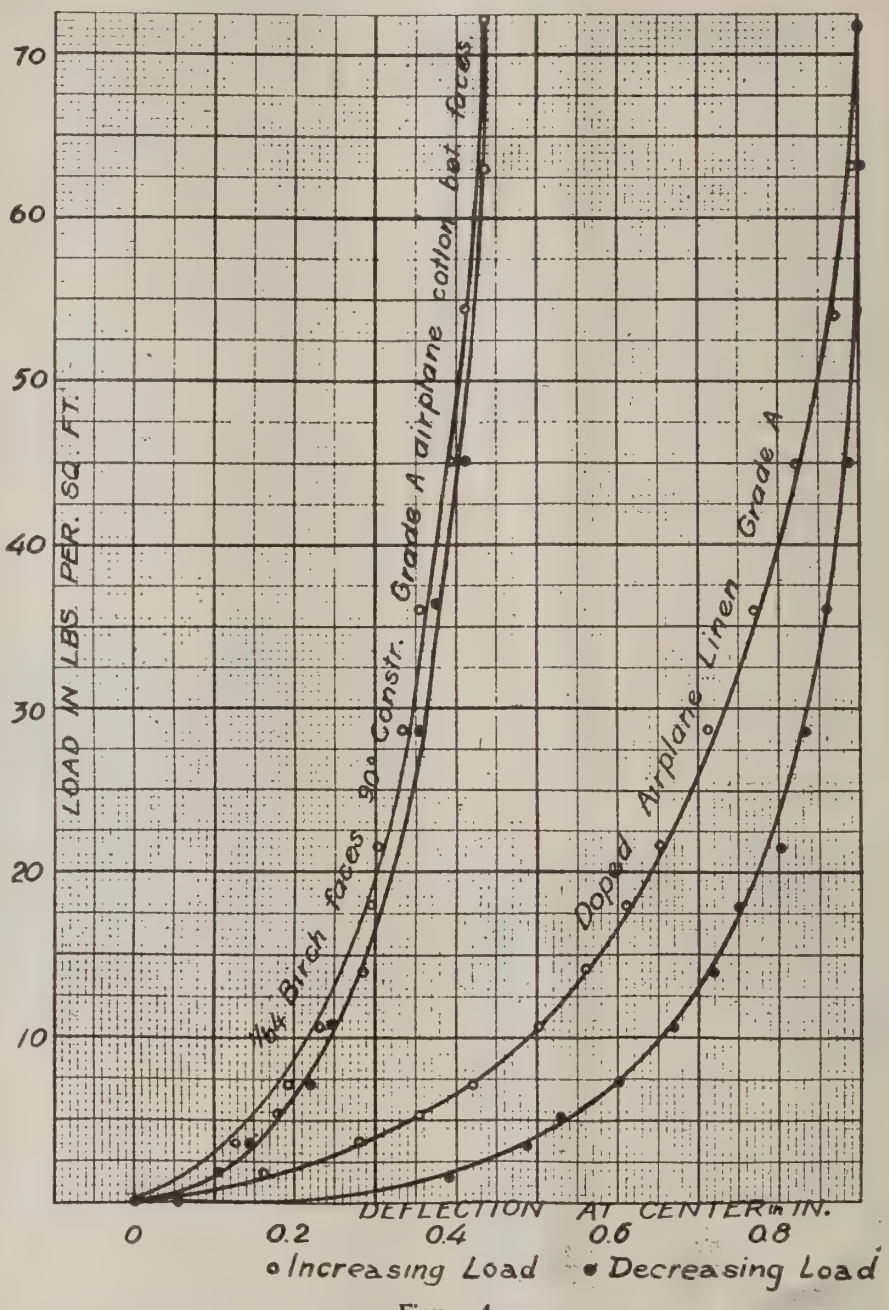


Figure 4

Load deflection curves. Sand load tests on plywood panels. Panels tacked on frames 18" x 18" inside dimensions

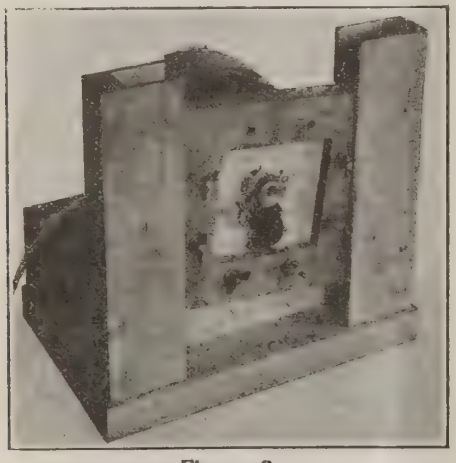

Figure 2

Apparatus for simulating whipping action to test the tear in an aeroplane covering ruptured by a projectile

Tearing Strength

When ruptured in flight by a projectile, an aeroplane covering may develop a serious tear, especially in the slip stream of the propeller, where it is subjected to the rapid succession of air pulsations. It was thought that such repeated stresses could be simulated by the whipping action of the apparatus shown in Figure 2. The test sheets were fastened in a wooden frame. A hole through the specimen admitted a cam mounted on a motor shaft operating at 1,800 r.p.m., the weight of the frame and sheet under test being supported by the cam. The throw of the cam, although only 1/16 inch, caused the frame to vibrate or shake in its guide so that the cam tore a gap in the plywood. The time to tear a gap one inch long was taken as the basis of comparison of the relative tearing resistance of the material.

The very thinnest three-ply wood made

PRELIMINARY NAVAL FLIGHT INSTRUCTION

By NICHOLAS S. SCHLOEDER

(*Concluded from page* 1057)

Spins

SPINNING nose dive is a broad term, applied to all manoeuvers which include a rapid descent, nose down, accompanied by rotation about an axis more or less coincident with the fuselage. This includes a tailspin, though in this country, there is a tendency to restrict the term to convolutions in which the axis of the machine is perpendicular and the descent and spin very rapid. There is unquestionably a distinction, involving certain pecularities about a common principle.

The three underlying principles of spins involve torque, the screw effect of divergent surfaces (rudder and elevator out of neutral), and the use of ailerons. Any or all of these may be included. The first two are the prime factors in a tailspin, the last, of a spinning nose dive (in the narrow sense). Loss of speed induces the first, speed the last one.

Consider torque first. The constant functioning of all the aerofoil surfaces alone prevents a machine from spinning in a direction opposite to that of the propeller, with the propeller shaft as the axis. Now when loss of speed occurs, as in a stall, the surfaces cease to function and consequently the machine starts to turn and rotate to the left. This is a common experience with power loops. Hence, climbing unduly on left turns, followed by a loss of aerofoil function, directly contributes to a spin. Even with the motor throttled, torque will assist. Whence all ordinary machines spin faster and easier to the left, especially with scouts with slow-speed motors of proportionately greater torque. While torque is thus merely a contributing factor, it is yet largely responsible for accidental spins by students, which are invariably to the left.

Briefly, the theory of a true tailspin lies in the screw action of divergent or off-set tail surfaces. In other words, the elevator is pulled back and the rudder is hard over.

The action of the elevator and rudder is as follows: The elevator function at first is very similar to that resulting from a stall, that is, if we eliminate the effect of the raised elevator during a tail slide. Inasmuch as the center of gravity is below the center of lift of the machine, and about in line with it on its fore and aft axis, it is evident, as the elevator is raised and the machine begins to stall, that the center of gravity moves in front of the center of lift. The nose of the machine is lifted by the depressing effect of the raised elevator, which thus acts as a lever with the center of lift as the fulcrum. Now, loss of speed follows a stall, and, as before mentioned, the center of gravity moves in front of the center of lift; hence, the elevator has more work to do, with less power of doing it, because the reduced speed diminishes its action. Consequently, the nose of the machine drops suddenly. Now, when the nose drops, speed is quickly regained, restoring the leverage of the elevator, which ordinarily, would again raise the nose. Another factor, however, prevents this, namely, the rudder.

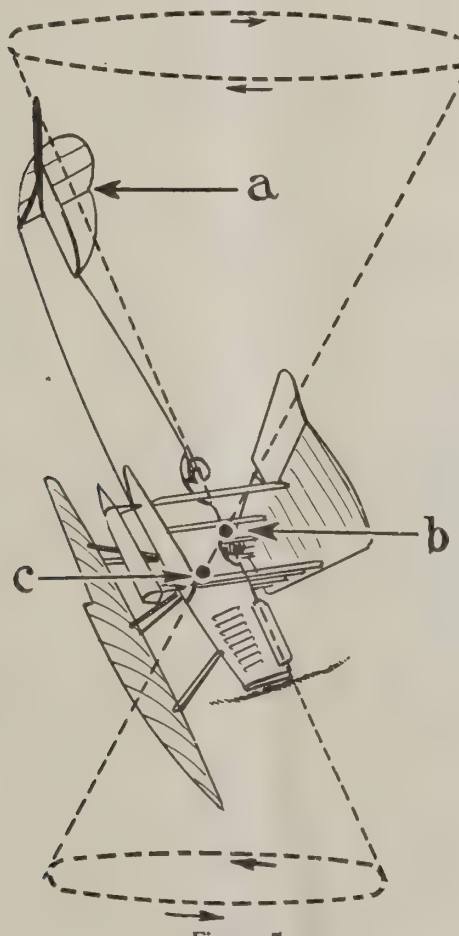

Figure 5

Diagram of a tail spin: , tail surfaces; *b*, fulcrum; *c*, center of gravity

A vertical keel surface is necessary for elevator action, otherwise the tail might slip off one way or other laterally, under stress. Hence, when such a keel plane surface is divergent, in the form of rudder "hard over," not only is the neutralizing effect of the prevention of lateral slip negatived, but it will give the direction of that slip. This actually happens, for it becomes easier for the elevators to slip off to one side, directed by the rudder, than it does to lift the nose, a spinning motion being thereby imparted, as is self-evident.

A machine in the position indicated by Fig. 5 is acted on by a set of opposing forces whose operation may be compared to a lever, the fulcrum being the center of pressure on lift of the main planes, with the elevator on one arm tending to lift the nose, while on the other the center of gravity holds it down; a dual decided by the rudder in favor of gravity.

As a practical matter, any position with elevators raised, rudder over, will result in a spin. The simplest way to spin is to throttle the engine, holding machine up, slowly pulling back controls to chest and then applying hard rudder. Some pilots first go into a stall, with or without power. Too much down rudder on a "flipper" turn or spiral will also cause a spin. Loss of speed where torque is involved will likewise contribute. Loss of speed is never otherwise the direct cause of a spin, as is sometimes erroneously supposed, but merely goes with the assumption of the screw position of the tail surfaces.

Neutralization of tail surfaces will immediately stop all normal spins. Only where torques or ailerons are involved, will any further action be necessary, such as ruddering against. In flat spins, rudder against. In accidental spins to left, cut spark. If from flipper turn or spiral, release wheel momentarily, which will neutralize ailerons. Always neutralize elevator, never more.

A spinning nose dive, in the narrow sense, is applied to a fast perpendicular spin which may be the result of several contributing factors. As will be seen by examination of diagram, the greater the relative force of the tail surfaces, the flatter will be the spin. Therefore by easing off on the tail surfaces, the descent will be made more precipitate. If at this time ailerons be used with the spin, this acts as a screw about their common center of pressure, which of course, is midway at the nose. Hence this tends to keep the nose down, and likewise more than compensates for loss of rotating moment.

In practical flying, a spinning nose dive often results from a "flipper" spiral, as the ailerons are held over. By aileroning with any ordinary spin, a spinning nose dive may be produced. To come out of it, it is necessary to add one feature to the ordinary practice of a neutralization of tail surfaces, i. e., by momentarily relaxing hold on the wheel the ailerons neutralize themselves at once. Pressure on ailerons may be very great in a spinning nose dive; indeed it is an effort to hold them over.

Taxiing On Water

Ability to manoeuver machine while in the water, particularly upon the final return to the beach, is of great importance. Indeed, collision with other machines along the beach is responsible for more minor breakages than any other mishap. The rules are simple, yet confusing.

If the approach to the beach involves a head wind, the controls are used quite as in ordinary flight, though with greater radius. If the wind is more or less parallel to the beach, and in order to keep machine on desired course it is necessary to turn nose to the windward, simply throttle engine. The machine acts as a weather-vane and swings into the wind. To turn nose to the leeward, open throttle and apply rudder as

usual. Never attempt to turn into wind by aid of rudder with power on. Furthermore, it is desirable in such cases to approach beach from leeward side. If a tail wind prevails, greater than the speed of taxiing, reverse control becomes necessary. Hence, in right turns, give left rudder; the wind catches the rear of the rudder surfaces which swing tail to left. Similarly to raise nose in choppy water, throw yoke forward as the wind strikes the upper surface of the depressed elevator and lowers the tail.

Ailerons assist in manoeuvering on the water. When machines are equipped with wing tip pontoons, ailerons are used to immerse pontoon on side toward which it is desired to turn, which thus acts as a pivot for a rapid turn. With engine throttled, always use reverse control.

Generally speaking, it is easier to turn to left than right because of torque. Approach beach as slowly as practical. Never head toward beach while still on the step, unless at a considerable distance. When leaving beach, proceed gradually; do not throw blast back on bystanders.

Flying Boats

Before concluding these remarks I will take up the special peculiarities of flying boats.

The differences of boat control is due to the peculiar distribution of the centers of lift, gravity, thrust and resistance It is exactly the reverse of that in tractor machines, and, theoretically, with the possibility of engine failure present, it is a more unstable arrangement. The center of thrust is above the center of resistance, the center of gravity behind the center of lift.

With power on, it can readily be seen that the first compensates the second, for the high thrust tends to depress the nose; the center of gravity to raise it. Now, with power off, this heavy tail condition is neutralized by a lifting tail; hence the necessity of throwing the controls forward and holding them in a glide. Where bank is involved, there is a tendency for the nose to come up, as may be assumed, since the high thrust no longer acts directly downward, but at an angle. Therefore "down rudder" can be used with greater freedom with steep turns than in the operation of tractor machines.

Another peculiarity is the balanced ailerons which makes their operation easy and which leads to overcontrol by the pilot. Furthermore in taking off, there is the sharp swerve to the left which the boat makes as it goes on the step and the tail lifts out of the rudder. This is only momentary and is compensated by a temporary application of hard right rudder.

The difficulty of F-boats is constituted largely by their difference from tractors, and not to an inherent complexity of operation. In fact, landings are easier for beginners, and I have succeeded in qualifying with them for solo by a measurably shorter period of instruction than with N-9's.

Students must be taught to operate F-boats from the left seat. The advantages of this are: (1) They may operate the throttle with the right hand, as customary; (2) Most instruments are on the left side, particularly, when later, they operate H-boats; (3) The fault of climbing on left turns is practically eliminated, as the student is on the inner and *lower* side when turning; the outer side of the bow above him tends to make him keep the nose down. The opposite is true of right hand turns, as he is then on the outer and *upper* side, but in this case a low angle of incidence is not so necessary; (4) As the bow of the machine slopes slightly from the center, there is a tendency among boat pilots to lower the wing on the opposite side; if the right wing is low it is more advantageous than the other, for, as before explained, the slight side slip compensates for torque and decreases the strain on right rudder.

The Aeromarine has an unusually high effective angle of climb, but the speed at such angle is very low. Consequently, the tail surfaces are not very effective, which leads to careless work, particularly with the rudder, which, shoved hard over, may lead to a spin. Otherwise I have discovered no particularities.

Care of the Machine

In conclusion, I migh state that the care of machine, knowledge of engine and detection of trouble; safety measures, such as examination of controls before flight, acquaintance with rules of the course; a constant lookout for other machines; the technique of the instruments, aerography, etc., are matters of vital importance. However, I haven't elucidated them as the strict compass of this paper aims to be nothing more than a treatise on actual flight instruction. Local conditions modify rules, and the student is referred to motor men and technicians for other points. Nor have I discussed the difficulties of aerial acrobatics, as I believe they are not within the compass of preliminary instruction.

A COMPENDIUM OF MISTAKES MADE BY STUDENTS

In Take-Offs

(1) In taking off, most students held controls forward too long after they had succeeded in getting the machine to plane on the step, which thereby caused it to "porpoise."

(2) Many students attempted to arrest a porpoise by movement of the elevators, instead of by withdrawing them to neutral.

(3) Many students dragged machine off water before it had attained sufficient flying speed, by holding controls too far back, which resulted in a series of bounces and the assumption of a dangerously high angle of climb upon finally taking the air, which at times almost resulted in a stall.

(4) Many students attempted to rock machine on the step by a vigorous movement of yoke back and forth, instead of a slight movement about neutral in rythm with the natural rock of the machine.

(5) All students have permitted wing tip pontoon to bury itself in the water when attaining step, which caused machine to swerve in its direction, and therefore out of the wind.

(6) Most students underestimated the amount of rudder control necessary before attaining step, which is considerably greater than that needed while planing or in flight.

(7) Many students after landing, and I had opened the throttle to proceed, lost sight of fact that the machine had not settled into water, but was still planing on step, so that when they threw yoke forward as if to attain the step, the nose was depressed suddenly and dangerously.

In Flight

(8) Most students failed to hold their course in straight flight until after some experience, and permitted machine to swerve gently to left because they did not maintain pressure on right rudder consistently.

(9) Some students on the other hand, held right rudder too steadily; hence did not have the much-needed flexibility in rudder action, which resulted in yawing.

(10) Many students flew with right wind low, because of insufficient right rudder; some with left wing low, because of too much right rudder.

(11) Many students attempted to affix certain point on rocker arms or machine and "line it up" with horizon. Too much reliance on this led to great confusion in absence of a clearly defined horizon, when obscured by mist.

(12) A common method of confusing horizon occurred as students approached mainland from the sea. They confused the edge of the shore with the horizon; hence, as they approached land, the nose dropped and the angle of climb decreased until it fell below normal.

(13) Some students interpreted injunction to nose down in rough weather to mean sudden movement of elevator controls. "Bumps" should not be "fought." A slow depression of nose while passing through adverse currents was all that was necessary.

(14) Most students over-controlled in flight; some were sluggish in control.

In Turning

(15) In first using the rudders a few students had difficulty in getting away from the bob-sled idea of foot-bar action, which is opposite to that in "Dep" control.

(16) Most students began turn by use of too much control, particularly the rudder.

(17) Skidding on a turn was far more common than slipping, particularly when to the left.

(18) Most students, when over-control had precipitated them in a sharp turn, aileroned hastily against the turn, ignoring the rudder, so that machine leveled out laterally in a decided skid. On straightening out the rudder, the turn came to an abrupt ending, before the desired change in direction was achieved.

(19) Nearly all students, because of haste in beginning turn, have, because they found it necessary to correct overcontrol, by controlling against turn, failed to turn as rapidly and smoothly as they would had they began the turn more cautiously.

(20) Many students, instead of depressing nose slightly before turn was begun, and keeping it at the initial degree of depression, did so after turn was started, until nose was below necessary angle. The nose of machine was thus alternately too high and too low.

In Landing

(21) After engine was throttled or died, many students did not assume gliding angle quickly enough. On the other hand, a few jerked controls forward unnecessarily.

(22) Leveling off too late was as common as leveling off too soon, and much more unwise.

(23) More students leveled off too much than too high.

(24) All students, on final contact with water, failed to have controls back enough, a cause of the great majority of imperfection in landing.

NAVAL and MILITARY AERONAUTICS

Experimental 24-Cylinder Liberty Engine Tested

Washington, D. C.—A short test of a 24-cylinder Liberty X-type motor has been conducted at McCook Field. The test engine was built of standard Liberty 12 parts. The changes involved were few, consisting in the main in the use of two regular crank case upper halves, one of which was somewhat altered, and special design connecting rods.

The following table compares the Liberty 12 and the experimental Liberty 24:

Horsepower (normal)—	
Liberty 24	673
Liberty 12	400
Pounds per H.P. (dry)—	
Liberty 24	1.97
Liberty 12	2.11
Gas consumption (pound per H. P. hour)—	
Liberty 24	.55
Liberty 12	.51

The experimental Liberty 24 compares favorably with successful tests of foreign motors of approximately the same power. An engine of this power, if run at the normal speed, would enable the use of a comparatively large slow-speed propeller without gear reduction, thus increasing propeller efficiency.

The following table compares the Liberty 24 and various high-powered foreign motors:

Motor	Vountry of manufacture	Rated horse power	Weight per h. p. (pounds)
De Dion	France	800	2.15
Liberty 24	U. S.	673-738*	1.97
Fiat A-14	Italy	600	2.36
Rolls-Royce "Candor"	England	600	....
Anzani 20	France	600	....
Renault 12-M	France	550	....
Salmson 18-Z	France	500	1.76
Napier "Lion"	England	450	1.86

*Experimental, not rated.

Inactive R. A. M.'s Permitted to Fly in Government Aircraft

Washington, D. C.—The commanding officer at any Air Service station where flying is authorized may permit qualified Reserve Military Aviators, who are in inactive status, to take such flights in Government aircraft as he deems advisable. Cross-country flights will not be made under this authority and no interference with the regular training or the operation of a station will be permitted.

Before exercising the authority given them in preceding paragraph, commanding officers of Air Service stations will be held responsible that the following conditions have been fulfilled:

(a) That individuals applying for such permission have fully and completely identified themselves—documentary evidence being required when necessary.

(b) That such individuals have demonstrated to the Flight Surgeon that their physical condition is satisfactory for solo flights.

(c) That no applicant is permitted to fly solo until he has been reported by a qualified instructor as competent to do so after an actual test in the air.

The foregoing restrictions have been found necessary as a result of the experience gained to date relative to flying engaged in under authority of Orders No. 30, O. D. A. S., 1919, which has been rescinded by this order. Commanding officers are directed to observe the spirit as well as the letter of these instructions to the end that Government property may not be needlessly destroyed nor the lives of over-enthusiastic pilots in poor physical condition, or whose flying efficiency has been lowered by too long an absence from flying, be needlessly endangered.

Flying Permits from Army and Navy Board of Aeronautic Cognizance No Longer Required

Washington, D. C.—The War Department authorizes publication of the following from the office of the Director of Air Service:

The President has revoked his proclamation making it necessary for all civilian fliers to apply for flying permits to the Joint Army and Navy Board of Aeronautic Cognizance. As legislation in connection with internation aerial regulations is pending in Congress concerning the issuance of flying licenses, it is not believed by the Army Air Service Joint Board that it is necessary or practical for municipalities or states to issue flying licenses until a national standard license is authorized.

Souther Field Personnel Ordered to Texas

Americus, Ga.—According to the local press orders have been received at Souther Field for the transfer of 121 enlisted men now stationed here to Ellington Field, Houston, Texas. As there are only 140 officers and men now stationed at the field, this order means the virtual abandonment of the post.

Summary of Status of Army Planes in United States

Washington, D. C.—The Air Service reports a total of 9,204 planes in the United States, 858, or 9 per cent, of which are in commission. The table shows the status of these planes as of August 7. The total does not include planes already delivered to concentration points for delivery to the Curtiss Corporation. The item in reserve includes planes of all types, foreign and domestic, in storage and at depots:

Status	Number.	Per cent. of total.
In reserve	7,369	80
Out of commission	977	11
In commission	858	9
Total	9.204	

3,162 Reserve Officers in Air Service

Washington, D. C.—Of the 15,646 commissioned officers discharged from the air service, 1,638 flying and 1,524 non-flying officers have entered the Reserve, a total of 20 per cent of the number discharged.

Air Service Demobilized 91 Per Cent Since November 11

Washington, D. C.—The Air Service reports a net decrease in strength to August 7 of 91 per cent.

The following table shows the present distribution of personnel as compared with that of November 11. The August 7 figures do not include 505 officers in transit or at demobilization camps awaiting discharge:

	Nov. 11	Aug. 7	% net dec.
Cadets	6,483	3	99.9
Enlisted men	167,986	13,562	92
Officers	20,554	3,426	83
Total	195.023	16.991	91

Participants in the balloon race, the feature of the Fort Omaha Aerial Carnival, from left to right: Lieut. Connolly, Lieut Huffman, Mr. A. Leo Stevens, Lieut.-Col. Jacob W. S. Wuest, Major O'Brien, Lieut. Thompson. Rear row: Capt. McKinley, Lieut. Neely, and Lieut. Jordan

FOREIGN NEWS

Aeroplane Lands on Jungfrau

Berne—Aviation Lieutenant Aikermann, accompanied by Major Isler, effected a landing on the summit of the Jungfrau on August 18.

The point where thier biplane was to have landed was marked by cinders in the snow, but the machine dropped into an air pocket and fell in deep snow 100 yards away from the landing place. The aviators were not hurt.

Perfect Record for Daily Blackpool-Manchester Service

Blackpool, Eng.—The daily passenger service between Manchester and Blackpool has run daily for three months without a forced landing. The fare is £4 4s single and £9 9s return flight. During the last week in July over 1,000 passengers were taken up at the Blackpool Aerodrome.

Farman Enterprise

Paris—The following advertisement appears weekly in the Paris "Daily Mail" for the Farman Company:

"*To the Belgian Victory Fetes by Aeroplane.*

"This week the Goliah will leave for Brussels as usual on Tuesday morning, returning to Paris on Friday morning. Passengers will thus be enabled to witness the splendid fetes that our Belgian allies are holding in celebration of victory.

"Messrs. Farman beg to announce that, besides the regular flights made by the Goliah, they can place at the disposal of business men or tourists a number of aero-taxis for one or two passengers and aero-limousines for parties of at least four passengers at the rate of 2 francs per kilometre and per person, as well as Goliah aerobuses for parties of at least ten passengers at the rate of 1 franc 25 centimes per kilometre and per person.

"It will be seen from the foregoing that the charge for an aeroplane flight is very nearly equal to and sometimes less than the charge for a journey by automobile."

Scotland-Norway Service Planned

Major Galpin, R. A. F., has arrived in Norway to negotiate with the Norsk Luftfartrederei and a British company to establish a passenger service between Scotland and Norway.

School of Military Aeronautics in Brazil

Rio de Janeiro—The French aeronautic mission, headed by Colonel Magnin are inaugurating a school of Military Aviation at Affonsos. Fifteen pilots will act as instructors.

There will be two courses; one for army pilots' license and one for aviation mechanics. Soldiers who qualify will be admitted to the school with the rank of sergeant. The facilities and equipment for instruction purposes at the school are of the best.

Sir Hugh Trenchard Receives Baronetcy

London—In recognition of the great services rendered during the war in connection with Royal Air Force during the war, His Majesty, King George, has conferred a boronetcy upon Air Vice-Marshal Sir H. Trenchard, K. C. B., D. S. O. A bounty of £10,000 has also been recently given Sir Trenchard.

England is ready for civilian aeronautics. Aerodromes are established at every point on the map

Air Force Personnel Slightly Reduced

London—A parliamentary paper recently issued showing the personnel of the staffs of the various Ministries, gives the following figures for the Air Force: November 11, 1918, 4,646; March, 1919, 4,090.

Turin-Rome Record Broken by Sia Machine

The aeroplane record, with passenger, from Turin to Rome, was broken on July 12th by Lieutenant Brack-Papa, flying the Fiat BR biplane equipped with a Fiat 700 h.p. 12-cylinder engine. The distance of 362 miles was covered in 2 hours 15 minutes, this giving an average speed of 161 miles an hour. The previous record with passenger over this route was 2 hours 50 minutes, established by Sergt. Stoppani on a Sia machine.

Sir Herbert Austin Decorated by King Albert

The King of the Belgians has conferred the title of Commandeur de l' Ordre de Leopold II upon Sir Herbert Austin, Managing Director of the Austin Motor Co., Ltd., in recognition of "constant and generous help given to this country in the course of the war."

Airship Control Turned Over to Air Ministry by Admiralty

London—According to announcement made in Parliament by Bonar Law, it has been decided to place the control of airships under the jurisdiction of the Air Ministry instead of the Admiralty.

Conditions of $50,000 "Daily Express" Contest

London.—Now that the Atlantic has been bridged by air in both heavier-than-air and lighter-than-air craft, the next step is to prove the practicability of commercial flying within the Empire.

With this object in view, the *Daily Express* offers a prize of £10,000 not only to prove the feasibility of commercial flying within the Empire, but also to bring the outlyng portions of the Empire into infinitely closer touch with the Mother country.

Australia has offered a similar prize to the first aircraft to fly there from the United Kingdom. There remains, therefore, the task of establishing aerial communication on a commercial basis with South Africa and India. This task the *Daily Express* proposes to carry out.

Conditions

In general, the terms and conditions of the £10,000 competition may be outlined as follows:

(*a*) All types of aircraft are eligible for entry.

(*b*) **The competition is open to all the world, except late enemy countries.**

(*c*) All aircraft entered must carry a useful load of at least a ton both on the outward and homeward flights.

(*d*) Each entrant must produce one aircraft for the flight to and from South Africa, and one aircraft of a similar type for the flight to and from India.

(*e*) The factors considered in the award will be:

Average reliability.
Airworthiness and general conduct of aircraft entered.
Average gain in speed over the established means of transport.

(*f*) As the aim is that each aircraft shall carry a useful load of saleable or exchangeable commodities or raw materials, it will be to the advantage of competitors to study the commercial situation as affecting this interchange.

(*g*) Particulars of entries will be announced within the next few days.

(*h*) Competitors may undertake the flights at any date between the closing of the entries list, which will be announced later, and June 1, 1920. Priority in completion will not prejudice the success of later but obviously more efficient performances.

(*i*) One complete failure by a competitor will involve disqualification for the award.

Further instructions as to the particulars and conditions of the competition will be announced later.

India and South Africa

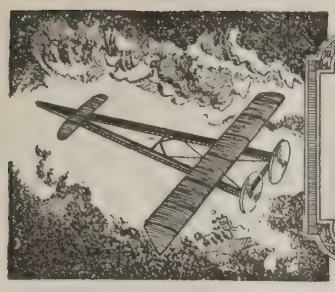
Peculiar importance is attached to the flight to the East, for these reasons:

(*a*) The vast potential possibilities of India commercially to the Empire.

(*b*) The delay in both sea and cable routes to India, which has been greatly aggravated by the war. This delay will continue for years to come to the detriment of both the United Kingdom and India.

(*c*) The fact that it is now established that the defence of the Indian frontiers in the future will rest chiefly in the air. The establishment of commercial air routes to and from India will have an enormous moral effect throughout the East, and may well eliminate the possibility of hostile incursions such as that recently undertaken by the Amir of Afghanistan.

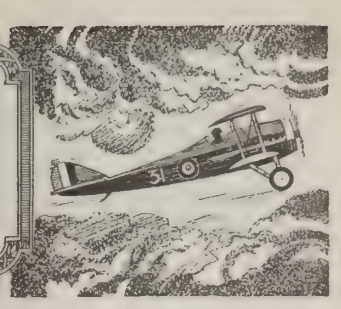
South Africa also is keenly alive to the great mutual benefits, both material and sentimental, which will accrue from regular aerial transport to and from the Mother country.



We hope, in due course, to publish details of the entries. At present Messrs. Vickers, of Atlantic fame, are considering the project, and as the "Vimy" appears a machine capable of carrying out the conditions of the competition, it is anticipated that they will enter. The Farman Company have entered one of their "Goliath" machines.

World's Altitude Record with Passenger Again Reported Broken

Paris—A new world's altitude record of 30,000 feet is said to have been established for an aeroplane with passenger on August 13 by Lieut. Weiss, the pilot, and Mechanician Begue, according to the newspaper *Auto*.



The flight, which took 52 minutes, was made at Villacoublay, near here. The aviators' instruments showed that they experienced a temperature of more than 25 degrees below zero.

The official figures on the ascent will be made public later.

Illinois Model Aero Club Note

By W. E. Schweitzer

THE Illinois Model Aero Club hand-launch duration contest was held Sunday, August 3, at Ashburn flying field. The weather was very threatening and twice the models were put away to avoid being wet by the passing clouds.

The contest was another of the series for the Laird Weaver trophy which is awarded each year to the club member having the highest average for the season. The cup was first won by W. D. Pease in 1916, next by W. R. Sprague in 1917 and last by W. E. Schweitzer in 1918 and in whose possession it is now.

The best duration of the day was made by W. E. Schweitzer, 133 seconds, W. D. Pease next with 114 seconds and E. C. Cook third with 89 seconds.

The results were as follows:

	Seconds		
J. J. Lucas	55.8	11	8.6
W. D. Pease	1.2	111.2	114
W. E. Schweitzer	105.2	133	129.4
W. Wrixon	5.6	25	22.2
E. C. Cook	89	0	0
H. Wells	26.2	40	22
R. Jaros	37.4	72	6.4

Several others were also out but without models.

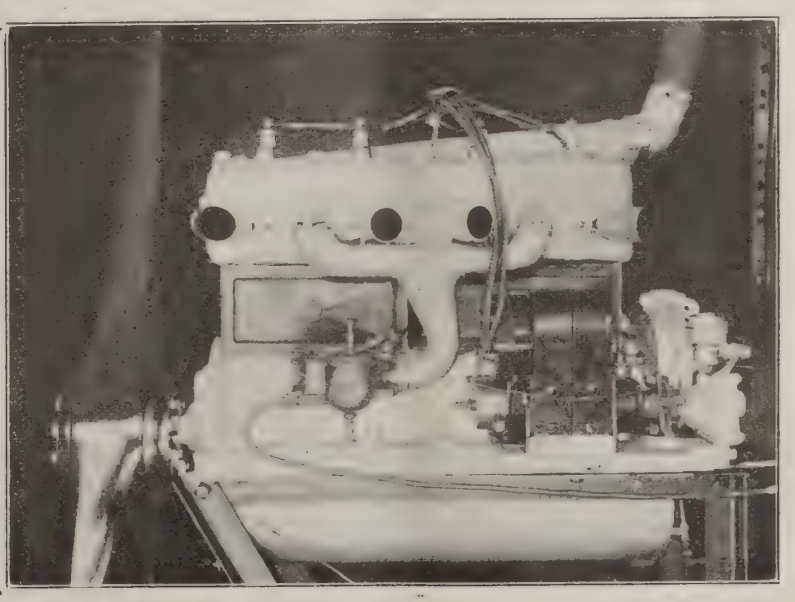
A number of large machines were also flying, some with passengers at $25 a hop, but most of them were just out for a spin. Buck Weaver, an old member of the club, left during the afternoon for Cleveland expecting to make Toledo that night and Cleveland the next day.

W. E. Schweitzer made several attempts at the R. O. G. distance record, but the longest flight, 3,034 feet, was 330 feet short.

The next contest for the club will be R. O. G. duration on August 17 followed by another hydro meet on Labor Day, September 1.

The Halford Aero Motor Constructed by Harry Herzog

AFTER reading Mr. McMahon's article on the construction of the Ford aeroplane it encouraged me to see if it was not possible to design a motor within reach of everybody's means.



The motor is strictly Ford as to compression valve area and timing; the pistons are aluminum with special rings lapped to perfect fit; the rods are standard type grooved for better oiling; they have a specially constructed dip which is the future of the lubrication of the entire motor; the cooling is thermo-syphon; the crankcase is special and contains one gallon of oil; the carburation is taken care of by a special carburetor for high speed work, and has given perfect results.

The ignition is Bosch magneto. There is an oil gauge for the crankcase level and the crankcase is divided so that it can run at a 25-degree angle without affecting the lubrication.

The propeller is bolted direct to crankshaft so that the crankshaft will not shift or distort itself; the crankshaft is threaded and has an adjustable ball thrust end bearing.

The tests of this motor have been more than satisfactory in results obtained. The motor is wonderfully flexible, and the temperature after two hours' running is all that can be desired for aircraft work.

The speed at one-eighth throttle is 750 R.P.M., and at full throttle, 1,900 R.P.M. The motor shows no vibration at any speed and indicates the even balance of the reciprocating parts. The motor is a guaranteed product and is constructed by the Auto Motor Repair Company, 478 Sterling Place, Brooklyn, N. Y.

The Ford Motor described above which has shown up pretty well in recent tests. This motor has all the original features of the Ford, but is timed and tuned up for the higher speed and extra lead which is called upon to overcome when mounted in an aeroplane

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Sojers

Two Tommies, dishevelled, torn with wounds, and altogether untidy, were on leave in London. As they stood in Trafalgar Square there approached a detachment of the Royal Life Guards in silver trappings, waving plumes, red coats, long varnished boots shining like mirrors, and white leather gauntlets.

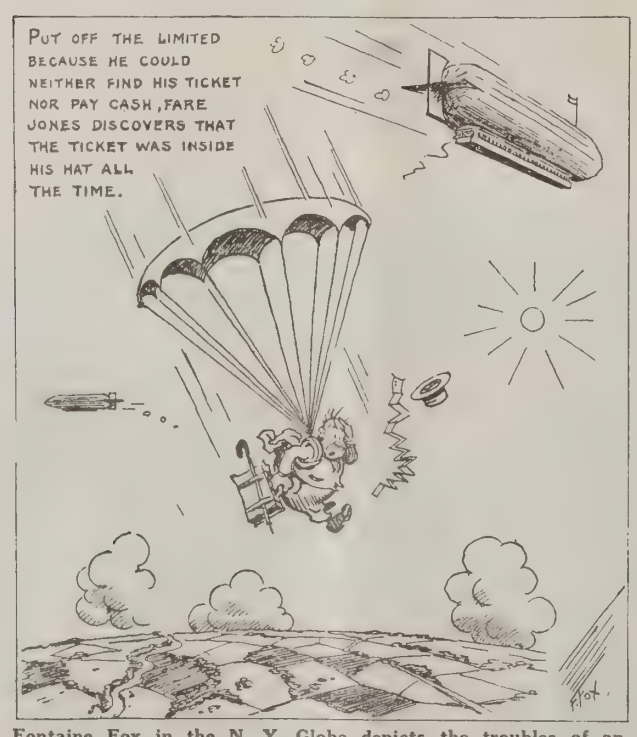
The Tommies looked on in silence for a moment and then one nudged his mate.

"Looka, Bill," he whispered in an awed voice, "Them's sojers!"—*New York Globe.*

Modern Curriculum

"Is this a strictly modern school for young women?"

"Judge for yourself."



"Well?"

"Dancing, motoring, aviation, and stump-speaking are featured in the curriculum."—*Birmingham Age-Herald.*

No Argument

After a young lawyer had talked nearly five hours to a jury, who felt like lynching him, his opponent, a grizzled old veteran, arose, looked sweetly at the judge, and said:

"Your honor, I will follow the example of my young friend who has just finished, and submit the case without argument."—*Life.*

Fontaine Fox in the N. Y. Globe depicts the troubles of an aerial traveller

Overheard at an Aerial Passenger Booking Office

The booking agent of a well-known passenger air line sends us a few samples of questions asked by prospective passengers:

"If I take my dog with me, do you think he will get sick?"

"Must I take Motherill's seasick remedy before I go up?"

"Can I stop off to see a friend on the way down?"

"If I get killed do you have to go to prison?"

"Are your pilots blonde or brunette? I read an article that only blonde pilots made good overseas."

"What happens if your engine stalls while we are in the air?"

"Will you promise not to fly too high?"

"How often have you been hurt?"

"Supposing I change my mind at the last moment, do I have to pay?"

How to Catch an Aviator

Wilmington, Del., Aug. 20 (Press dispatch)—"I know we'd catch an aviator," laughed Miss May Rupert, as, with her sisters, Misses Anna and Amy, they greeted Lieut. Charles Potter, Army aviator, as he landed on the lawn in front or their place, Rupert Farm, at Sedgley.

A few minutes later two more fliers landed into the girls' net and the sextet were seated on the lawn having tea when Lieut. Floyd A. Wilson, commander of the squadron, dashed up in a motor car an hour later.

"Where have you been?" queried the worried officer. "When I saw you circling over the city and then disappear I thought you had been killed."

The three culprits looked sheepish and then the girls explained. They had heard of the expected arrival of the air photographic expedition from Langley Field, near Washington, and when they were out motoring yesterday and saw Lieut. Wilson, who had come ahead of the others to prepare for their arrival, putting out his landing "T" near Greenville, they conceived the idea of constructing a similar "T" on their own place and catching some aviators.

With bed sheets they fashioned the two arms of the "T" which are used to direct aviators to their landing field, spread the cross on their lawn and awaited results. When Lieut. Pottery, flying in advance, espied the mark he alighted to the Rupert farm. The other two men missed both marks and landed at the country club. Later, learning where their companion had landed, they again "took off" and joined him at the farm.

Bring Your Own to Hendon Drome

"Hendon.—The afternoon of Saturday, July 12, was quite as exciting as usual, perhaps more so, as the Summer Meeting was postponed, and only two passenger-carrying carroty "Avros" disturbed the peaceful sight of the trains going by. It had rained quite unpleasantly in the morning, but cleared up quite nicely in the afternoon. It would have been possible to hold the meeting, as rain does not interfere with determined aviators, but the public would not have been very pleased to sit on the wet forms. It strikes one that perhaps after all these meetings are not held entirely for the amusement of the Grahame-White Aviation Co. Despite the fact that there were only about a dozen visitors, it was necessary to wait nearly half-an-hour to obtain tea."—From *Aeronautics* (London).

The Valentine Crew Valsparring the stern propeller of the R-34

Propellers of R-34 protected with Valspar—

BEFORE starting the homeward trip inspection of the propellers of the British dirigible R-34 showed that the flight to America had badly injured the varnish, leaving the laminated blades in a dangerous condition.

At Major Scott's direction Valspar Varnish was used to refinish the propellers because he knew that Valspar was absolutely waterproof and elastic enough to stand the terrific vibration without cracking.

The photograph shows the Valentine crew at their difficult task of Valsparring the stern propeller while the giant dirigible swung hundreds of feet back and forth across the field.

Hardly an hour after the varnishing was finished the remarkable drying qualities of Valspar were accidentally proven when tons of water ballast were dumped on the forward propeller, and a few moments later the hot engine exhaust beat against it for ten or fifteen minutes. But already the Valspar had set and no harm was done.

In air service as in marine work you can always depend absolutely on Valspar — it is accident-proof.

done credit to a large factory devoted entirely to the business of building planes. Something of the character of the work done at these depots can be realized when it is stated that it does not consist simply of the minor repair of a broken wing section or a slight defect in engine, but in the majority of cases amounts to the complete overhauling of a motor and the entire rebuilding of the plane.

Routing a Job Through the Shop

To understand adequately the amount of work done on one machine it is necessary to visualize a total wreck as it is unloaded from the railroad car, with hardly a stick of wood or piece of metal apparently in usable condition, and then see the repaired plane a few days later completely rebuilt and newly varnished displaying the Red, White and Blue Bull's-eye of the Air Service on the wings, and ready to take the air for active service again. Not only have the men of this depot repaired almost hopelessly damaged planes and engines, but they have also completely constructed a plane from the ground up, and turned it out in as perfect condition as an aeroplane from any recognized factory. An excellent way to obtain an idea of the repair work done by the aeroplane mechanics is to follow a job through the shop. The main shop buildings are the Aeroplane Assembly and the Engine Repair, two long wooden structures adjoining each other sufficiently closely for effective co-operation. The lumber shed which feeds the Aeroplane Assembly is conveniently located near one end of that building, as is also the Dope House, to which the plane goes for varnishing. Right behind the Engine Repair is the Aero Supply Building, where an enormous stock of aeroplane supplies is always kept on hand, so that it takes but a short step to secure needed materials. The aeroplane wrecks are unloaded on the shipping platform of the Aeroplane Assembly Building, where they find themselves almost immediately in the Dismantling Department, located near the receiving entrance of the building. Here the engine is taken out and sent over to the Engine Repair Building, to go through the various processes of overhauling. This overhauling includes, first, a trip to the washroom, where all the parts are thoroughly cleaned and the carbon scraped off: then follows a rigid inspection to see which parts are to be rejected. Such parts are replaced by new ones, and others susceptible of repair are repaired. Then begins the work of reassembling. When the engine is again completely set up it is swung by chains onto an overhead rail and pushed out to the motor blocks, where it is subjected to a two-hour test, after which it is ready for installation in the plane.

Let us now follow the fuselage in its journey through the Aeroplane Assembly Building. First, the old fabric is stripped off and the wings, landing gear and tail surfaces removed. Each separate part is tagged with the number of the aeroplane from which it was taken, and sent to its proper department, where it undergoes close inspection, and, if defective, is replaced by a new part. The fuselage frame is then set up, carefully examined, and notes made of the repairs needed. Then it moves on a few yards further to the "First Assembly," where the process of repairing begins. Broken longerons are spliced and new straps and fittings put on. In the "Second Assembly" wires and turn-buckles are replaced, and the gas tank, seat rack and engine bed is added. The fuselage is then put on an aligning stand and is trued up, after which it moves on to the "Sub-Assembly," where it receives the instrument board with equipment. The next move finds it in the "Fabric Department," where the covering is put on, after which it is ready for varnishing in the "Dope House." Meanwhile the wheels and landing gear are being repaired or replaced, and when the fuselage has been varnished and lettered it comes out to the "Final Assembly," where it is put on a stand, the engine is "dropped in" and the radiator added. Then the landing gear is affixed, cowl, streamline, center section, empinage and wings follow, and the thing finally stands forth as an aeroplane all complete. A final test of the motor follows, and then if the whole job is found satisfactory the plane is again taken down for packing and crating; or if its destination is some field within the "flying delivery" radius the plane is hauled over to the Speedway motor course on trucks and trailers, tested in flight, and then flown away.

A VIEW IN THE FINAL ASSEMBLY ROOM

This photograph shows planes in all stages of final assembly, from those awaiting the installation of the engine to others, further back in the picture, that are ready for shipment. In this picture can be seen the chains of the overhead shop railroad, made by the Richardson-Wilcox Mfg. Company, Aurora, Ill., and used throughout the shops; for surface transportation a shop truck made by the Automatic Transportation Co. of Buffalo is used

The Future of the Repair Depots

From all this it will be seen that the aviation repair depots have been a vitally necessary and important link in the great chain of air service institutions. Additional depots had been planned and would doubtless now have been in operation had the war continued longer. What the fate will be of the three depots now existing remains to be determined. If the Southern flying fields, where all-year-round flying can be carried on, are to be maintained in peace times, it would seem logical to retain both the Dallas and Montgomery repair depots. In the North, however, the fields are not used in the winter, although some of them could be; and in any case they have been closed since the ending of the war.

Tests on Thin Plywood

(*Continued from page* 1136)

of 1/150-inch veneer was unsatisfactory in tearing resistance. Thicker material, even without cotton fabric, made of veneer such as 1/55-inch basswood or 1/80-inch birch, proved to be much more resistant to tearing than doped linen. The addition of a cloth fabric further increased the tearing resistance.

Rigidity

In order to retain the desired theoretical aerofoil, the covering of an aeroplane wing or tail surface must be rigid; that is, it must stretch comparatively little upon the application of a distributed load, such as the air pressure.

Rigidity was measured at the Laboratory by the magnitude of the load at a given deflection, as determined by the sand-load test shown in Figure 3. The sand is retained by the frame shown in Figure 3, and leveled off on the surface. The deflection at the center of the sheet was measured at each load, and later plotted against the corresponding load in pounds per square foot of surface.

The curves of Figure 4 show what a marked difference in rigidity exists between the doped linen and thin plywood of satisfactory construction. The superiority of the thin plywood over the linen extends over the entire range of loads used (up to 70 pounds per square foot), but is most marked for the lower loads.

Stability

Aeroplane covering which becomes loose or abnormally tight, or develops waves with changing atmospheric humidities is quite unsatisfactory. Such changes in stretch are here described under the term "lack of stability."

Stability determinations were made upon a variety of thin plywood constructions by placing out-of-doors the sheets tacked upon heavy frames, thereby exposing them to changes in humidity. Stability was measured in this test by changes in sag with changing humidity. A small weight was placed upon the center of a test sheet tacked upon the frame and the deflection at the center of the sheet was measured. The panel was then turned over and deflection measurements were again taken. The sum of the two deflections is spoken of as the "sag."

Thin plywood, especially when unprotected, absorbs moisture very rapidly, so that there is an appreciable loosening and tightening with changing atmospheric humidity. The tests showed the necessity of giving the sheets several coats of a good waterproof finish. Such coatings as aluminum leaf, barytes enamel, and spar varnish were tried. Their effectiveness in keeping out moisture was in the order in which they are named.

Numerous tests have shown that for a three-ply construction the shrinkage from the soaked to the oven-dry condition is somewhat greater than 0.5 per cent across the grain of the faces and somewhat less than 0.5 per cent parallel to the grain of the faces.

Thin Spanish cedar plywood covered with two coats of barytes enamel and one coat of spar varnish changed moisture content only about 4 per cent upon exposure to almost 100 per cent relative humidity for a continuous period of four days. Similar material protected with an aluminum leaf coating absorbed less than 1 per cent moisture in the same period. Unprotected plywood is, however, not as stable as doped aeroplane linen.

Conclusions

The tests indicate that while plywood sheets may be made that will compare favorably in weight with doped linen, they cannot be manufactured on a commercial scale in the present state of the plywood industry; and, furthermore, that such very thin sheets are unsatisfactory in toughness, tearing strength and stability.

The most promising material consists of two plies of about 1/55-inch low-density veneer, such as yellow poplar, or 1/80-inch high density veneer, such as birch, glued with the grain of one ply at right angles to the grain of the other ply, and having a sheet of cotton cloth incorporated between the plies. Such material weighs almost 2.5 times as much as doped aeroplane linen and somewhat more than this when coated with various finishes. While the weight of thin plywood of this kind is considerably greater than that of doped linen, its tensile strength is more than three times as great as the tensile strength of linen. It is far more rigid than linen and has greater resistance in tearing. Two-ply wood, however, requires a framework or ribbing to hold it in place to best advantage and to prevent the formation of shallow waves. Therefore, in cases where large surfaces are to be covered without supporting framework, a standard three-ply wood may be more desirable.

THE BRITISH AIRCRAFT COMPETITION—WHY NOT AN AMERICAN COMPETITION?

THE complete regulations governing the British aircraft competition have been received by AERIAL AGE in an official communication from the British Air Ministry. The regulations are of special interest, as they establish a basis for developing regulations for technical competitions dealing with different aspects of aeronautic progress. This progressive step of the British Government opens a way for the American Government to do likewise.

The official communication follows:

A committee composed of members of the Air Ministry and of the Aviation Industry has been sitting for the past two months under the chairmanship of the Under-Secretary of State for Air to consider the question of encouraging the future development of aviation on the lines of increased safety. A large number of witnesses has been called, including constructors and designers and representatives of public who are interested in aviation. It has been decided, as stated in Parliament, to institute a competition open to the British Empire. Prizes to the value of £64,000 will be awarded by the Government under the conditions which are set out below:

Rules for a Competition for Aircraft to Further the Attainment of Safety of Air Travel

(a) The aim of these competitions is to obtain a real advance in the efficiency and design of aeroplanes and seaplanes, more especially with the view of increasing the safety of air travel. The rules drawn up are intended to secure this object.

(b) As regards the rules for aeroplanes, it is recognized that the conditions are, generally speaking, easier for the small machine than for the large. The object in this is to attract a large number of competitors from among designers of small machines.

(c) The present competitions are not directly aimed at engine reliability, nor at economy in fuel and oil consumption, although these are of the first importance, but chiefly at the attainment of efficiency in the machine itself. A much longer time is required to produce radical improvements in engines than in machines, and since it is intended that the present competitions should be held early next year, it has been decided to concentrate attention on the machine on this occasion.

Aeroplanes

1. A competition will be held commencing on March 1, 1920, with the object of ascertaining the best types of aeroplanes which will be safe to travel in, and in particular be capable of alighting in and rising from a small space.

2. Two types of aeroplanes will be entered for the competition:

(a) Small type with a total carrying capacity of 2 persons (including pilot).

(b) Large type with seating accommodation for 15 persons (exclusive of crew).

3. Machines and engines must have been designed and constructed within the British Empire. This rule will not, however, apply in the case of such secondary equipment as ignition system, carburetors and instruments.

4. Machines are to fulfil all conditions required for a certificate of airworthiness, and are to carry parachutes for all persons for whom accommodation is provided, including crew.

5. Each machine must be capable of flying level at or above the following speeds with full load at ground level:

Small Type	*Large Type*
100 m.p.m.	90 m.p.h.

And must also be capable of flying level at or below the following speeds with full load at ground level:

Small Type	*Large Type*
40 m.p.h.	45 m.p.h.

Each machine must also be capable of climbing not less than:

Small Type	*Large Type*
500 feet in the first minute, starting from ground level.	350 feet in the first minute, starting from ground level.

6. *Landing and Getting Off Test*

(a) A circle will be marked out on open ground to represent a field surrounded by obstacles. This circle will be of the following diameter:

Small machines.....175 yards
Large machines .....275 yards

The obstacles will be represented by a continuous string or tape with streamers attached, 50 feet from the ground, of such a nature as to be easily broken by an aeroplane.

(b) The landing to be made in still air. Still air includes any wind not exceeding 5 miles per hour at ground level.

(c) During landing the machine is not to side slip nor to turn after reaching the obstacles until it is on the ground. Once it has touched the ground the machine may turn in any direction.

(d) The machine to come to a standstill before reaching the marks representing the boundary of the field.

(e) After landing, the machine to get out of the same field over the 50-foot obstacle in still air (as defined in sub. para. b), no turn to be allowed until clear of the obstacle on the far side.

(f) No braking device operated by the engine may be used during landing.

(g) Any landing or taking off gear used must be integral with the machine.

(h) No landing apparatus may be used that in the opinion of the judges would be liable to cause undue damages to an aerodrome, e. g., a claw attached to the machine as used on certain types of German machines would not be allowed, but the ordinary knife edge on a tail skid would be allowed.

(j) Both landing and taking off to be with full load.

(k) Each machine will be allowed two trial attempts (which are definitely not to be counted as tests), and thereafter will be allowed four attempts, of which two must be successful.

7. *Reliability Test*

(a) In the case of the small type, each machine must carry out a series of two flights of 3½ hours each at a speed through the air of not less than 80 miles per hour, starting with full load. Between flights machines will be left untouched, and under seal if necessary, a period of not more than 30 minutes being allowed before the second flight, for the purpose of filling up and normal examination.

No parts of the machine to be adjusted or changed without permission from the judges.

(b) In the case of the large type, each machine must carry out one flight of 7 hours' duration at a speed through the air of not less than 75 miles per hour, starting with full load. Pilots may be changed during these flights.

8. Machines must be capable of landing from a height of 500 feet, with their engines switched off or completely throttled down.

9. In a machine having two or more engines the stoppage or retardation of any one engine must not prevent the machine from flying level, nor cause it to get out of control.

10. Machines must be capable of being started from the cockpit or cabin without undue muscular exertion on the part of the pilot.

11. Machines to be capable of flying at cruising speed for 5 minutes without the use of any controls or stabilizing devices. Controls may be locked during this test.

12. Machines to be capable of standing unattended and not fastened down in a wind of 10 miles per hour, blowing in any direction with reference to the machine.

13. The design of the machines to be such that the risk of the machine turning over on a rough ground is reduced to a minimum.

14. Each machine to be provided with a complete outfit for pegging it out in the open. This outfit will not be carried as part of the load during tests.

15. In order to be eligible for prizes, machines must fulfil the conditions and tests laid down in Rules 3 to 14, inclusive. Marks will be awarded for soundness and quality of construction, for general features and for exceeding the specified requirements in Rules 5 and 6.

16. "Soundness and quality of construction" will include:

(a) Fire protection, including use of self-sealing tanks, position of tanks, (from the point of view of safety from fire in event of a crash); fire-fighting appliances and accessibility of same.

(b) Reliability of petrol, oil, and water systems, and facilities for seeing if all tanks are full.

(c) Durability of machine, including propeller (any advantages due to metal construction may be taken into account).

(d) Simplicity of design and accessibility of parts.

(e) Absence of vibration in the machine.

17. "General features" will include:

(a) Efficiency and ease of control.

(b) Unrestricted field of view to the front for the pilot.

(c) Silence, as affecting occupants of the machine, including crew.

(d) Comfort generally, including warmth.

(e) Self-starting devices.

(f) Method of wind screening adopted.

(g) Convenience for use of instruments.

(h) Freedom of entry and exit for occupants.

8. With reference to Rule 6, marks will be allotted for the capabilities of machines to land in an area more restricted than that used for the tests.

In judging this, the point vertically below the point where the centre line of the machine crosses the tape will be marked on the ground and the maximum distance reached by the wheels of the undercarriage will be measured in a straight line from this point.

19. Marks will be allotted for exceeding the minimum high speed and for flying less than the maximum low speed.

20. The judges will have regard to the method of fitting parachutes and especially to the means of exit by parachute afforded to the occupants of the large machine and will allot marks for the same.

21. Marks will be allotted for the convenience of pegging out the machine in the open and for the lightness of the apparatus necessary for pegging down.

22. Marks will not be given on account of the number of engines installed.

23. The following will be the allotment of marks:

Soundness and quality of construction (Rule 16).

Sub-para.	(a)	Maximum	8
"	(b)	"	8
"	(c)	"	6
"	(d)	"	6
"	(e)	"	4 Maximum total 32

General Features. (Rule 17).

Sub-para.	(a)	Maximum	6
"	(b)	"	6
"	(c)	"	6
"	(d)	"	5
"	(e)	"	5
"	(f)	"	3
"	(g)	"	3
"	(h)	"	2 Maximum total 36

High Speed. For each m.p.h. in excess of required minimum (Rule 5)	½	No maximum
Low Speed. For each m.p.h. below required maximum (Rule 5)	1	No maximum
Landing. For every complete 3 yards less than the distance allowed in 175 yards for small and 275 yards for large machines (Rules 6 and 18)	1	No maximum

	Max. Marks
Method of fitting parachutes (Rule 20)	5
Convenience of pegging out (Rule 21)	3

Forfeiture of Marks

	Max. Marks
Adjusting or changing parts in reliability test. See Rule 7 (a).	8
For every two minutes or portion of 2 minutes in excess of the maximum time allowed for filling, 1 mark. See Rule 7 (a)	8

24. With reference to Rule 6, when carrying out the landing and getting off test, machines will start with the full load of petrol and oil and will be allowed to fly for 20 minutes. If they have not carried out their tests by the end of that period, they must land and fill up again.

25. The type of propeller used on any machine must be the same for all the tests.

26. Full load is to include: Instruments as under

Revolution counter.
Aneroid.
Air speed indicator.
Turn indicator.
Compass.
Watch.
Oil pressure gauge (when necessary).
Air pressure indicator (when necessary).
Radiator thermometer (when necessary).

Small Type	*Large Type*
Petrol and oil sufficient to fly 450 miles at 3,000 feet. In addition, a load of 440 lbs., to include weight of pilot and passenger, if carried, and parachute.	Petrol and oil sufficient to fly 600 miles at 3,000 feet. In addition, a load of 3,000 lbs., to include weight of passengers, if carried, and also to include parachute, but not to include the weight of crew.

27. Petrol and oil for the tests and as far as possible accommodation (at owner's risk) for the machines will be supplied free by the Government.

28. The judges shall have the right to disqualify any machine that is very seriously defective in any respect.

29. The judges shall have the right to put up a service pilot to fly any of the machines, should they consider it desirable to do so, at Government risk.

All tests will, however, be carried out by the entrant's pilot.

30. During or on completion of any flying test, if it is necessary to effect any repairs to the machine after landing, it will be considered to have failed in that particular test.

This does not apply to cases where the machine is by the judges' instructions being flown by a pilot other than the entrant's pilot.

31. Any entrant may enter more than one type of machine.

32. If a machine is wrecked during the competition, it may, at the discretion of the judges, be replaced by another, but the replacement machine must carry out the whole programme of tests.

33. The decision of the judges shall be final in all matters affecting the competition.

34. The Government does not accept any liability in respect of accidents during the competition, whether resulting in injury to personnel or damage to the machine, except as specified in Rule 29.

35. The Government reserves the right to adjourn the competition.

36. The Government reserves the right to withhold any or all of the prizes if in the opinion of the judges no real advance on existing designs is shown.

37. The Government will, if the entrant agrees, buy the machine of each type winning the first prize, the designs to remain the property of the manufacturers. The maximum prices payable under this head will be:

Small Type	*Large Type*
£4,000	£10,000

38. The following prizes are offered:

Small Type	*Large Type*
1st prize £10,000	£20,000
2nd prize 4,000	8,000
3rd prize 2,000	4,000

39. Entries to close December 31st.

Seaplanes

1. A competition will be held on March 1, 1920, with the object of ascertaining the best types of Float Seaplanes or Boat Seaplanes in which it will be safe to travel, and in particular to be capable of alighting on and arising from land as well as water.

2. Each machine entered for the competition will be provided with seating accommodation for four persons, exclusive of the crew.

3. Machines and engines must have been designed and constructed within the British Empire. This rule will not apply in the case of such secondary equipment as ignition system carburetors and instruments.

4. Machines to fulfil all conditions required for a certificate of airworthiness, and to carry parachutes and lifebelts for all persons for whom accommodation is provided including the crew. The boat or floats must be so sub-divided that if perforated in any one part each float still remains positive buoyancy.

5. Each machine must be capable of flying level at or above a speed of 80 knots with full load at sea level, and must also be capable of flying level at or below a speed of 40 knots with full load at sea level.

Machines must be capable of climbing not less than 350 feet per minute in the first minute.

6. *Alighting and Getting Off Tests.* (a) Getting off test (sea). Machines will be required to take off with full load and clear an obstacle 25 feet above sea level in a distance not exceeding 300 yards from a position of rest.

(b) Alighting test (land.) Machines will be required to land on a smooth aerodrome over an obstacle 25 feet in height and to come to rest in a distance not exceeding 400 yards, measured in a straight line from the point where the obstacle is crossed. For this test machines will be required to carry full load less 50% total and oil.

(c) Getting off test (land). Machines will be required to take off a smooth aerodrome with full load and clear an obstacle 25 feet in height in a distance not exceeding 400 yards from a position of rest.

(d) The above tests are to be made in still air which for the purposes of this competition will be regarded as any wind velocity not exceeding five statue miles per hour.

(e) During landing the machine is not to side-slip nor to turn after reaching the obstacle until it is on the ground. Once it has touched the ground the machine may turn in any direction.

(f) No braking device operated by the engine may be used during landing.

(g) Any landing or taking off gear used must be integral with the machine.

(h) No landing apparatus may be used that in the opinion of the Judges would be liable to cause undue damage to an aerodrome.

(i) In test (a), (b) and (c) above, machines will be allowed four attempts, of which two must be successful.

7. *Test of Reliability in Flight.* (a) Each machine must carry out a flight of five hours at a speed through the air of not less than 70 knots, starting with full load.

Pilots may be changed during this flight.

8. *Mooring Out Tests.* (a) Fair weather. Each machine will be moored to a buoy by its own crew and using its own mooring tackle (other than the buoy and its moorings) for a period of 24 hours during the first 23 hours, of which time it will be left unattended. The crew will not be allowed on board to pump out the bilges at any time during this test except with the permission of the judges in case of emergency.

At the conclusion of the 24 hours period the crew will be allowed on board the machine, will be got under way by its own crew and under its own power and will be required to carry out a short flying test within a period of one hour from the conclusion of the 24 hours period.

The test will be carried out under fair weather conditions. Marks will be allotted for rapidity in getting under way.

Moderate weather. Each machine will be moored to a buoy for a period of not less than 12 hours, unattended under the following conditions:

Locality—Roadstead sheltered from the open sea.

Wind—From 4 to 6 on the Beaufort Scale.

Marks will be allotted for the general condition of the machine at the conclusion of this test, and its behavior during the test.

In both the above tests the ordinary average tidal currents existing round the coast of the British Isles may be experienced.

9. Rough water getting off and alighting test.

Each machine will be required to carry out a test of getting off and alighting on disturbed water, which in the opinion of the judges constitutes a moderate sea. The condition in any case will not exceed State 4 in the sea disturbance scale. (Waves under 4 feet in height).

10. Machines will be required to carry out a test of being towed in a moderate sea as defined in paragraph (9) in a circle of approximately ¼ mile radius.

11. Each machine must make a figure of eight course around two buoys 100 yards apart and within a rectangle measuring 200 yards by 100 yards, in a wind not exceeding 15 m.p.h., the sea to be smooth and the tide at slackwater.

12. Each machine must be capable of moving on the water, under its own power, for a period of at least 30 minutes and at a speed of not less than 10 knots, and not greater than 20 knots.

13. Each machine will be required to carry an anchor and sea anchor, as well as its own mooring tackle and to anchor on good holding ground with its own gear and remain fast in a wind of 10 m.p.h. and with tidal current not exceeding 3 knots.

14. In a machine having two or more engines, the stoppage or retardation of one engine must not cause the machine to get out of control.

15. Machines must be capable of flying at cruising speeds for three minutes without the use of any control or stabilizing devices. Controls may be locked during the test.

16. Machines in the round flying position must take up and maintain a gliding angle, when the engine or engines are cut off without the use of any controls or stabilizing devices.

17. After stalling, (1) machines must be capable of recovering flying speed and complete control without a loss of more than 500 feet of height.

18. Machines must be capable of being started from the cockpit or cabin without undue muscular exertion.

19. (1) In order to be eligible for prizes, machines must fulfill the conditions and carry out the tests laid down in paragraphs 2 to 18 inclusive. Marks will be awarded for soundness and quality of construction, for general features, for general behaviour afloat, and for exceeding the specified requirements in Rules 5 and 8 (a).

20. (2) Soundness and quality of construction will include:

(a) Fire protection, including use of self-sealing tanks, position of tanks (from the point of view of safety from fire in event of a crash), fire-fighting appliances and accessibility of same.

(b) Reliability of petrol, oil and water systems, and facilities for seeing if all tanks are full.

(c) Durability of petrol, oil and

(d) Durability of machine, including propeller (any advantages due to metal construction may be taken into account).

(e) Simplicity of design and accessibility of parts.

(f) Absence of vibration in the machine.

(g) Ease of repair, especially in regard to the hull or floats.

21. (3) General features will include:

(a) Efficiency and ease of control.
(b) Unrestricted field of view to the point for the pilot.
(c) Silence as affecting occupants of the machine.
(d) Comfort generally including warmth.
(e) Self starting devices.
(f) Convenience of mooring and anchoring arrangements.
(g) Method of wind screen adopted.
(h) Convenience for use of instruments.
(i) Freedom of entering and exit for occupants.
(j) Bilge pump arrangements.

22. Behaviour afloat will include:

(a) Stability at rest.
(b) Water stability at all speeds.
(c) Minimum spray at all speeds.

23. Marks will be allotted for exceeding the minimum high speed and flying less than the maximum low speed.

24. The judges will have regard to the method of fitting parachutes and especially to the means of exit by parachute afforded to the occupants and will allot marks for the same.

25. Marks will not be given on account of the number of engines installed.

26. The following will be the allotment of marks:

Soundness and quality of construction (*Rule* 20)

(a) 8
(b) 8
(c) 6
(d) 6
(e) 4
(f) 4. Maximum total 36.

General features (*Rule* 21)

(a) 6
(b) 6
(c) 6
(d) 5
(e) 5
(f) 5
(g) 3
(h) 3

The News of the Week

Seaplane Tours Planned

Atlantic City.—Extensive seaplane cruises along the Atlantic coast, to take place this fall and winter, were announced recently by Captain Charles J. Glidden, chairman of the Committee on Aerial Tours of the Aerial League of America, who is investigating the facilities for landing seaplanes at different points along the Atlantic coast. Captain Glidden is the donor of the Glidden Aeroplane Efficiency Trophy.

Among the seaplane cruises announced by Captain Glidden will be cruises from Atlantic City to Baltimore, Washington and Norfolk and from Atlantic City to Florida and the Gulf. Other cruises will visit New England ports, while others will follow the Mississippi and other great American rivers. Seaplane cruises from Atlantic City to New York and up the Hudson will be among the first to be organized. Captain Glidden also announced that winter cruises on the Pacific and Gulf Coast will be organized this winter. There are also under consideration Pan-American seaplane tours and cruises, the first of which will be seaplane cruises from Atlantic City along the Atlantic coast to Key West and from Key West to Havana and from there to Hayti and Porto Rico. Other tours of this nature will go from Key West by way of the Isla de Pinos, Great Cayman, Swan Island, Gordo Cays, Quito Sueno and Saint Andrew's.

To discuss these plans a conference was held at the Curtiss Flying Station in Atlantic City recently, at which were present Captain Charles J. Glidden, Mr. Henry Woodhouse, vice-president of the Aerial League of America; Mr. Albert T. Bell, president of the Atlantic City Aero Club; Mr. Earle L. Ovington, president of the Curtiss Flying Station, and Mr. A. S. Abell, 3d.

Army and Navy Balloonists to Compete for Championship Cup

St. Louis, Mo.—The Army and Navy balloon pilots will compete for a silver trophy to be awarded to the military balloon champions of the United States. The race takes place at St. Louis on September 26 under the auspices of the Missouri Aeronautical Reserve, the donors of the cup. Each side will be represented by three balloons and three teams, the personnel of which is to be announced in the near future.

Major A. B. Lambert is in charge of the preparations for the race. Elaborate plans are being made at the camp of the Missouri Aeronautical Reserve. The large number of free balloon pilots which were trained for the dirigible and balloon services of the Army and Navy makes the race of great interest to the men of both services

Maynard Wins New York-Toronto Race

New York, N. Y.—Lieutenant B. W. Maynard, U. S. A., flying a De Haviland Four with a Liberty motor, made the fastest time for the round trip between New York and Toronto in the New York-Toronto Aerial Derby last week. The official results show that his flying time was 465¼ minutes, an average of more than two miles a minute for 1,042 miles. Under a ruling of General Menoher, Lieutenant Maynard is not eligible to the cash prizes offered by Hotel Commodore. These total $10,000.

There were fifty-two entries for the flight and twenty-eight finished the round trip. Three made second starts after failing in first efforts. Excellent flying time, as shown by the summary, were made by many of the contestants despite the poor weather conditions encountered.

The following is the order of finish and the flying time of the contestants in the New York-Toronto Air Race: Lieut. B. W. Maynard, DH-4, 465¼; Lieut. H. H. George, DH-4, 520¾; Lieut. D. B. Gish, DH-4, 524¼; Col. G. C. Brandt, DH-4, 545¼; Lieut. M. J. Plumb, DH-4, 559¾; Lieut. P. H. Logan, Le Pere, 562; Lieut. Ben Adams, DH-4, 564; Lieut. John P. Roullot, DH-4, 570¼; Major R. Schroeder, VE-7, 572; Sergeant C. B. Coombs, DH-9, 576; Col. H. E. Hartney, SE-5A, 589¾; Lieut. R. T. Midkiff, DH-4, 597½; Lieut. Ross Kirkpatrick, DH-4, 602¼; Lieut. C. F. Brown, DH-4, 607¾; Lieut. Charles Colt, SE-5A, 621½; Lieut. F. T. Honsigner, DH-4, 635; Roland Rholfs, Oriole, 667¼; Captain C. W. Cook, Fokker, 759½; Major A. B. Gilkeson, DH-4, 764¼; C. S. Jones, JN-4D, 833½; Lieut. W. R. Taylor, JN-4H, 836½; Captain H. B. Chandler, JN-4H, 895¼; Captain R. H. Depew, JN-4D, 898½; Captain S. S. Moore, Can. JN-4, 912½; Lieut. L. W. Bertrand, Can. Trng., 1285¼; Lieut. Wallace Young, JN-4H, 1313½; Col. Wm. C. Barker, Fokker, 1434½; Lieut. C. A. Schiller, Can. JN-4, 1520¾; Major J. W. Simons, DH-4, 1536¾; and O. S. Parmer, Standard, 3323.

Rochester-New York Flight in Less Than Two Hours

Hempstead, N. Y.—It is announced that the five DeHaviland aeroplanes which constitute the Dallas-Boston squadron flew from Rochester to New York, a distance of 285 miles, in 110 minutes, an average of 156 miles an hour.

Aerial Landing Field at Sunnyside, Washington

Spokane, Wash.—Commercial flying at Sunnyside, Wash., is to be inaugurated by Lieutenant Parshall. A suitable flying field is being prepared.

Lieutenant Parshall will also fly to Lewiston, Idaho, to give exhibitions at the local fair. At Yakima recently Parshall carried the youngest passenger on the coast, Miss Ruth O'Keefe, aged 21 months.

Foreign Trade Convention Urges Establishment of Aerodromes

Chicago, Ill.—At the Sixth National Foreign Trade Convention, recently held at Chicago, a resolution was adopted recommending the establishment of aerodromes at trade centers as an aid in the extension of foreign trade. The text of the resolution follows:

"The Convention suggests to local Chambers of Commerce the advisability of having public aerodromes in all centers that expect to develop large foreign markets in order that prompt delivery of plans and specifications, blueprints and invoices may be made from seaports to the interior. Until such aerodromes are built, local manufacturers will be under the disadvantage of being denied the privilege of speedy receipt of desired documents from great centers of distribution."

The Le Pere biplane, equipped with super-charger, in which Major R. W. Schroeder made the high altitude speed record of 137 miles an hour at 18,400 feet

Low Parachute Jump from Seaplane

New York, N. Y.—Major Orde Lees, late of the Royal Air Force, took a leap from a low-flying seaplane on August 28 near the Statue of Liberty to demonstrate the reliability of the "Guardian Angel" parachute for short drops.

The experiment was being undertaken to secure scientific data and photographs of the exact manner in which the parachute performs when dropped with a man from a fast moving aeroplane. It is hoped that the result will show that an aviator escaping from his burning or crippled machine need have no fear of being drowned or of being enveloped in his parachute should he happen to fall in the water.

The aeroplane from which the jump was made is a three-passenger Curtiss flying-boat, piloted by Lieut. McCulloch, who piloted the NC-3 in the trans-Atlantic flight. Major Lees holds the low altitude record, made when he dropped from London Bridge, a height of 153 feet.

American Escadrille in Polish Army to Fight Bolsheviki

Paris.—An American aviation squadron is being formed in Paris on the lines of the Lafayette Escadrille to fight with the Poles against the Bolsheviki. Major M. C. Fauntleroy, of Chicago, and Capt. M. C. Cooper, of Jacksonville, Fla., have received authority from Gen. Rosvedowski, head of the Polish Military Mission, to form a squadron of aviators who, like themselves, have seen service in war aviation.

Among the men already enrolled are Lieut. Edward J. Corsi, of Brooklyn; Lieut. George M. Crawford, of Wilmington, Del.; Lieut. Kenneth Shrewsbury, of Huntington, W. Va., and Lieut. Carl H. Clark, of Tulsa, Okla. The squadron will be designated the Kosciusko Squadron, after the Polish national hero and Washington's aide-de-camp.

This American squadron is expected to go to Poland September 15. Its members will hold the rank they held in the American Army, but the corresponding Polish pay being less, the men are making a sacrifice. No term of service is fixed, but the aviators will not be called upon to serve more than a year.

Curtiss Company Plans New Air Routes

Buffalo, N. Y.—The Curtiss Aeroplane and Motor Corporation is to establish several new air passenger routes. The planes will be manned by aviators who served in the war and will be specially suited to passenger traffic.

The cities on the routes are to be Rochester, Syracuse, Utica, Albany and New York on one, Erie and Pittsburgh on another, and Hamilton and Toronto on a Canadian route. The route across New York State probably will be opened this fall and the Pennsylvania and Canadian routes next spring.

Planes Fly in Formation under New York's Bridges

Mineola, L. I.—Attempting a new feat, three aviators flew under the five suspension bridges over the East River. The planes flew in triangular formation, starting from Hazelhurst Field at 1:30 P. M., and returning at 2:35 P. M., on August 28.

Lieutenant A. S. Roberts headed the three planes, with Lieutenant C. H. Burgess, who was recently the bridegroom in an aeroplane wedding at Sheepshead Bay, on his right, and Lieutenant N. L. Elliott on his left.

W. G. Ranels who is representing the interests of the British & Colonial Aeroplane Co., manufacturers of Bristol aeroplanes, in America

British Air Attaché Seeks R.A.F. Officers Who Have Not Received Their Decorations

Washington, D. C.—The British Air Attaché, Air Commodore L. E. O. Charlton, D.S.O., has issued a notice for the attention of all Royal Air Force officers and other ranks, now resident in the United States or its overseas possessions, who have been awarded the Distinguished Flying Cross or the Air Force Cross, and who are not yet in possession of the same, should communicate, without delay, to him at the British Embassy, Washington, D. C., in order that arrangements may be made for the due presentation of the decorations.

The above also applies to officers late of the Aviation Service (Army or Navy) of the United States, who are similarly entitled, but who are demobilized, therefore not necessarily in communication with the authorities in this matter.

Around U. S. Flight Resumed

Washington, D. C.—The War Department authorizes publication of the following statement from the Director of the Air Service:

"After a delay at Plattsburg, N. Y., due to necessary repairs, Colonel R. S. Hartz, of the Army Air Service, has again taken the air in a Martin Bomber on his trip around the United States. With Lieutenants E. E. Harmon and L. A. Smith, and a mechanic, he flew from Plattsburg to Buffalo on August 30, a distance of 326 miles, in five hours, with one stop for gas. He expects to leave this morning, August 31, for Cleveland."

Four Year Old Aviatrix Demands Loops

New York, N. Y.—Miss Virginia Marie Waibel, four-year-old daughter of Mrs. John J. Waibel, of Brooklyn, N. Y., not satisfied with straight away flights, is demanding loops and other stunts on her flights. She is a regular passenger at Dana C. De Hart's Aerodrome, Hillside Avenue, Queens. Recently she took a 23-mile flight at an altitude of 2,100 feet. Her mother accompanied her and Dana C. De Hart piloted the plane.

Fast Flight from Buffalo to New York

J. D. Hill, a pilot aviator, of Buffalo, arrived at Mineola, L. I., on August 22 in a Curtiss Oriole machine, after flying from Buffalo, a distance of 440 miles, in four hours and ten minutes. The time established a record for this trip.

1,000 Miles of Aerial Honeymoon Completed

Spokane, Wash.—Finishing the first 1,000 miles of a 5,000 mile honeymoon tour, Lieutenant Floyd Kelso and bride, of Kennewick, Wash., arrived in Spokane, the last lap being from Coulee City, Wash., which was covered at a mile-a-minute flight. The bride of a week is enjoying her novel experience immensely.

Kelso is flying a Curtiss machine purchased from the United States aviation department. Next summer he plans to purchase a three-seater 'plane with a limousine body and to fly from Buffalo, N. Y., to Seattle. Meantime the happy pair will continue their daily flights in the Pacific Northwest until the cold weather drives them to terra firma.

Lieutenant Floyd Kelso and his bride landing at Spokane, Wash., after completing 1,000 miles of their 5,000 mile aerial honeymoon

The AIRCRAFT TRADE REVIEW

W. A. Bishop Heads Interallied Aircraft Corporation

New York, N. Y.—The Interallied Aircraft Corporation recently received its incorporation papers under the laws of the State of New York, to sell and manufacture foreign and domestic aeroplanes, seaplanes, motors and accessories. It is already in a position to deliver twenty-five Curtiss training, in excellent condition and with full equipment.

W. A. Bishop, the Canadian ace of aces, is president of the company; Reed G. Landis, second ranking American ace, and W. G. Barker, R.A.F., vice-presidents; J. W. M. Richardson, treasurer; W. R. Lott, secretary; Chas. H. Payne and C. S. Macdonald, general and assistant managers, respectively. Offices have been established at 185 Madison Avenue, New York.

William G. Ranels Represents Bristol Here

New York, N. Y.—Mr. William G. Ranels has recently opened an office at 512 Fifth Avenue, and represents in the United States the interests of the British & Colonial Aeroplane Co., Ltd., Bristol, England.

Mr. Ranels was sent abroad by the War Department early in June, 1917, in connection with aviation matters and during two years was located in London as an Aviation Technical Representative of the U. S. Air Service.

The British & Colonial Aeroplane Co., Ltd., was established February, 1910, at a time when the importance of the future open to aircraft was scarcely realized. Remarkable progress has been made since the foundation of the company and it now maintains an enviable position in the industry.

The directors of the company have secured the services of the highest authorities in theory and best practical exponents of aviation, the sole object being to produce the most reliable types of machines and to organize methods by which every improvement and research development could be immediately embodied.

Within twelve months of the formation of the company, "Bristol" aeroplanes were flying in England, India, Australia, South Africa, Italy, Russia, Roumania and Spain—the remarkable record in the progress of the new industry.

At the beginning of the war approximately 80 per cent of the British service pilots had been trained at the "Bristol" schools from date of establishment, March, 1910.

At the opening of the war several types of "Bristol" machines were utilized by the government. During the period of the war many successful types of machines were developed, practically all of which were adopted by the British Government and put into production for service.

Consistent with the policy of the company, now that hostilities have ceased, plans have been prepared for the rapid development of types of machines suitable for commercial and sporting purposes. The work of developing planes suitable for military purposes will also be continued.

Capt. F. S. Barnwell, chief designer, who has been with the company for a number of years, will continue on the lines of progressive design. The unlimited facilities for manufacture of all types of aeroplanes will be fully maintained to meet the demand for machines for pleasure, commercial and defense purposes.

Spokane Aviation Companies in Merger

Spokane, Wash.—A merger of local aviation interests has taken place, and the Northwest Aircraft Corporation emerges as the successor to the Northwest Aircraft Company and the Western Aircraft Corporation. Foster Russell, consulting engineer and aviator, will be the manager of the consolidated concern. Thomas W. Symons, Jr., late of the army, will also be identified with the concern. He is an instructor.

Mr. Symons, who will be in charge of all flying, is reputed one of the most skilled pilots in the northwest. His experience includes training at the flying instructors' school at Brooks field and seven months as flying instructor at Call field and Souther field. At Souther field Symons, after being instructor in all stages of flying, including acrobatics, was made flight commander and late officer in charge of flying.

Foster Russell had experience at eight different fields, was picked for a pursuit pilot and is experienced in the flying of the fast Thomas Morse scout planes which were equipped with Gnome rotary motors. He now holds a commission as lieutenant in the air service reserve on flying status.

B. L. D. Company to Manufacture Small Aeroplanes

The B. L. D. Aeroplane Company, Inc., whose flying field is located at Springfield, L. I., on the Merrick Road, are very active carrying passengers every fair day.

The field is located within New York City limits and is about ten minutes from Jamaica.

Two machines equipped with Hall-Scott motors are in constant use. William Diehl, a civilian army instructor and an old pilot, and Howard W. French, who is one of the first 100 R. M. A.'s with 1,000 flying hours' experience, are the pilots.

Mr. R. Brodell has been active in aeronautical circles for some time and is now working on the designs of light aeroplanes to be manufactured in quantities.

Poor Weather Conditions On New York-Bellefonte Lap

Washington, D. C.—Flying across the mountains from New York to Bellefonte, Pa., has proven to be the most difficult route of the Air Mail Service. This is in part due to the fact that the valleys and cities are blotted out by the early morning ground fogs, leaving only the tops of the ridges exposed as landmarks to aviators. It is also due in part to the changeable velocity and direction of the winds over the 215 miles trip from Belmont Field on Long Island to Bellefonte in the heart of the mountains, due to the variety of topographical changes in the way of valleys and mountains. Also the greatest wind velocities are found during the summer time in that region. This is shown in the variations of speed of the fast planes of the Air Mail Service.

Out of 101 trips, 39 were made at speeds ranging from 101 to 132 miles per hour, and 39 trips were made at speeds between 81 and 100 miles per hour. There were only four trips in a period of nearly two months in which the wind was strong enough to hold the speed down to less than 60 miles an hour.

The following is an analysis according to speed of the 101 runs.

	Stevens	Lewis	Anglin	Logg	Total

Detroit Selects Landing Field

Detroit, Mich.—After an exhaustive study of available sites, the City Planning and Improvement Commission, of which T. Glenn Phillips is director, has recommended the development of a 320-acre plat on Plymouth road, eight miles out of the city, as an aviation field.

Several months ago the City Plan and Improvement Commission was instructed by the Council to select prospective sites for a permanent municipal field after Morrow Field was excluded from the possibilities. The commission has several sites under consideration but has chosen the Plymouth road tract as the most desirable and practical for Detroit's use.

Following the decision that this field was most adapted to the city's needs, a committee of aviators was invited to inspect the field by the commission.

The party consisted of Mr. Phillips, Col. Sidney D. Waldon, Street Railway Commissioner and formerly a member of the United States Aviation Board at Washington; Col. Vincent of the Packard Motor Car Co., who is developing a 100-acre tract for the company as an aviation field; Mason Rumney, William E. Metzger, former president of the Detroit Automobile Club, and Lieut. H. D. Copland, former army aviator, and other aviation enthusiasts.

The tract measures one and one-half by one-half miles and lies in an east-and-west direction, and this direction is best adapted to local conditions where west winds prevail.

The new Pennsylvania Railroad route crosses one end of the tract and the Pere Marquette another, making convenient delivery of provisions, equipment, gasoline and other aeroplane necessities a point in its favor. Except for a gradual slope eastward, the field is comparatively flat.

The site can be purchased by the city at a condemnation price of $200,000.

American Express Company's London-Paris Aerial Express and Passenger Service

London.—The American Express Company virtually has completed arrangements through its tourist department for daily air passenger and baggage service between London and Paris, according to a cable dispatch received by the New York *Sun*. "Our plan," said William Gourlay, the company's manager for the United Kingdom, "is to have facilities available whereby a man or woman can leave London in the morning, fly to Paris and transact business there, and return to London in time for dinner, and vice versa. The arrangements are in the final stages now with the British and French Governments. We expect that customs officials will be posted at each end of the aeroplane route for the specific purpose of checking the baggage of arriving tourists.

"The ship will be installed and operating during October. There will be two grades of travel, both first class, one in an aeroplane carrying one or two passengers and costing approximately $100 for a flight one way and the other in a large air bus carrying fifteen passengers, for which the fare will be about $60 a person.

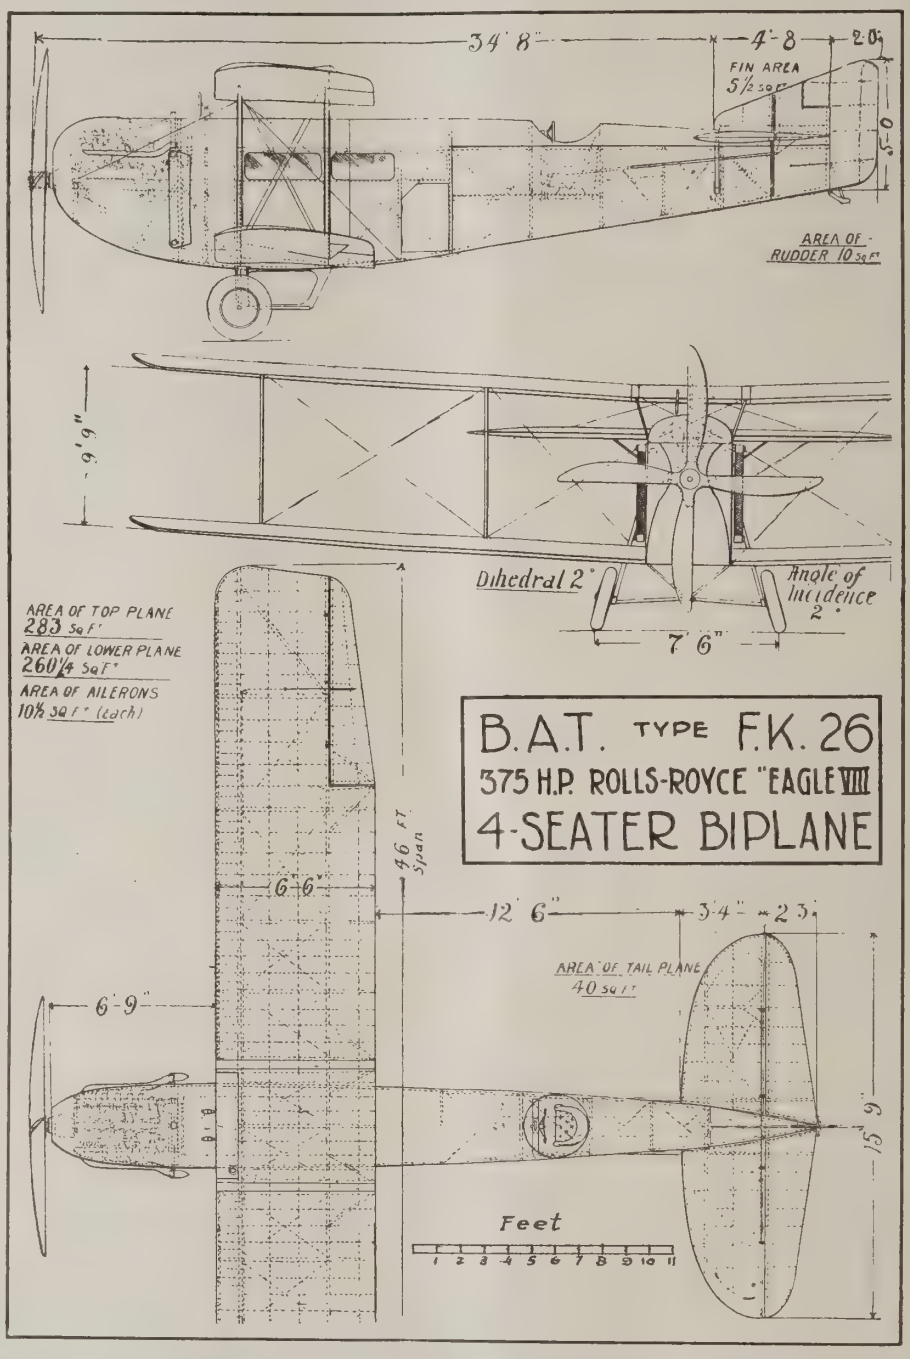
"We shall start with the air bus leaving three times a week and the aeroplanes daily.

"Automobiles will convey passengers from their hotels to and from the aerodromes, located respectively on the outskirts of London and Paris. The tickets issued will be after the style of steamships with a clause by which the passengers assume the risk for the journey. Each passenger will be allowed to carry a single piece of baggage, preferably no larger than a suitcase. Those going by airbus can travel in their ordinary civilian clothes, while passengers for the faster going aeroplanes will be supplied with headmasks and goggles.

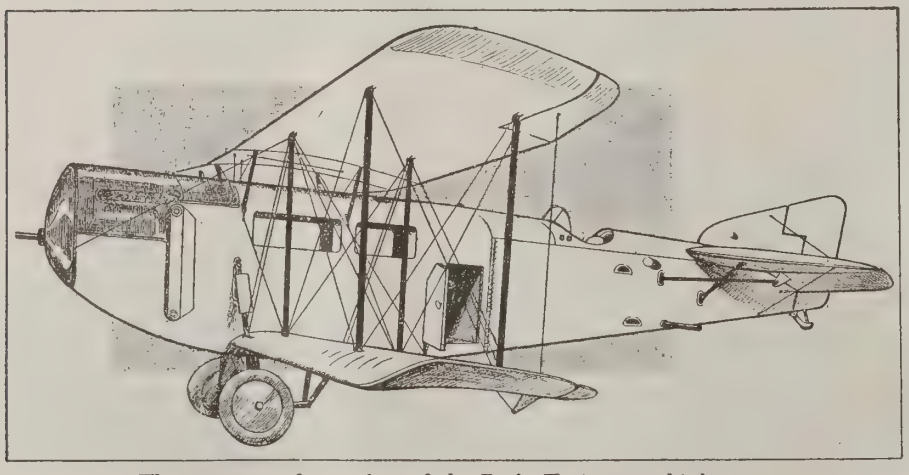
"The minimum time for the journey will be three hours, while four hours will be the maximum period in the air. The present time by train and boat between London and Paris is nine hours and costs about $20."

Mr. Gourlay was asked if other air routes had been blocked out for regular passenger services. He replied: "Yes, before the year is out we shall have aeroplanes meeting all arriving passenger ships at Liverpool and Southampton.

Aerial Mail being landed at Woodland Hills Aviation Field, Cleveland, Ohio



THE B. A. T. FOUR-SEATER BIPLANE

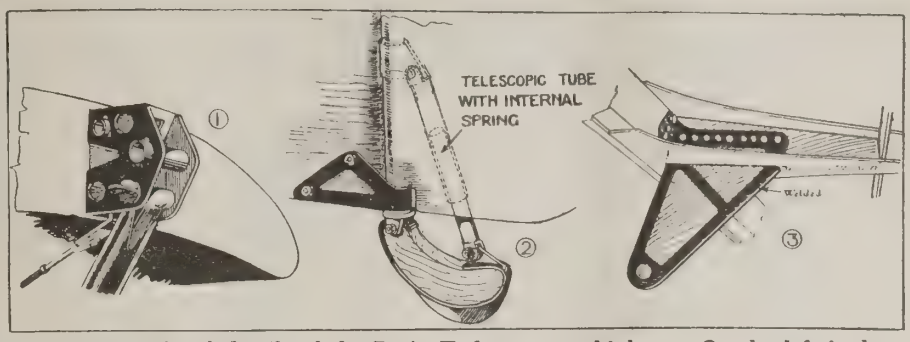


ONE of the first, if not *the* first, post-War "commercial" aeroplanes has just been completed by the British Aerial Transport Co., Ltd., at their works at Willesden. By post-War commercial aeroplane is meant a machine designed since the Armistice, specially for commercial work—either passenger, mail or goods—and *not* a war machine converted for this purpose. In this particular case, the B.A.T. F.K. 26, described in *Flight* has been designed either for passenger work or for carrying mails, there being accommodation for four passengers, besides the pilot in the former case, whilst for the latter purpose it is merely a question of adapting the passenger cabin to meet the requirements for this kind of work. The machine is original in many respects, but is at the same time of absolutely straightforward design, free from "cranky" features.

F.K. 26 is a single-engine tractor biplane, and as may be seen from the accompanying scale drawings, the general lay-out of the "weight items" is efficient and well thought out. The position of the pilot, well aft in the main planes, is such that it enables him to have an excellent view in all directions.

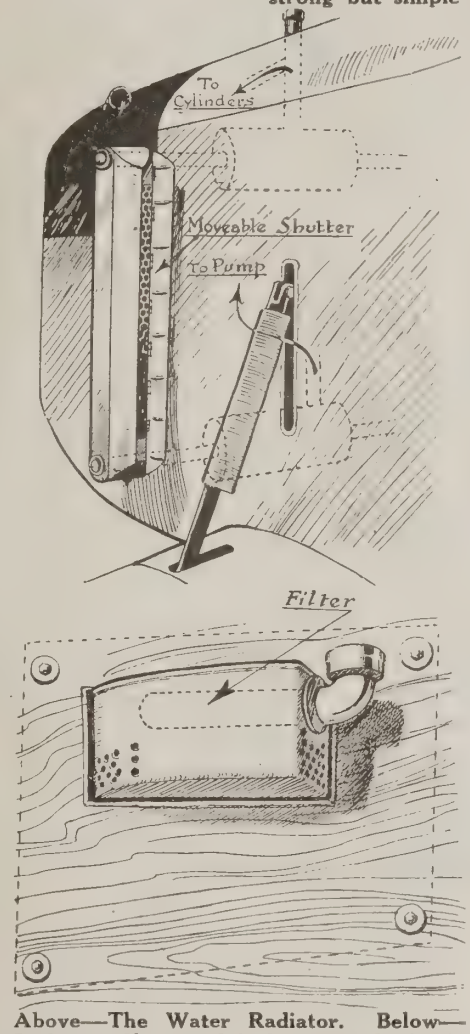
The fuselage, which is 30 ft. 10 in. in length, is of rectangular section, very deep near the wings and tapering to a vertical knife-edge at the rear. Two different forms of construction are employed in the fuselage, the front half, from the nose to the end of the passenger cabin, being built up of three-ply and formers in a similar manner to that obtaining in the German Albatross machines, whilst the rear half is of the conventional girder construction. Both systems, however, have many interesting features. There are four main longerons, of about 1½ by 1¼ in. L-section (solid where necessary), running from end to end, and one additional longeron of similar section in the front half situated between the upper and lower longerons on each side, level with the line of thrust. These longerons are of ash in front and spruce in rear portions. In all there are five transverse formers in the front half of the fuselage, built up mainly of H-section members reinforced by three-ply, and varying in shape and structure as shown in one of the accompany diagrams. There are also diagonal H-section struts between each former, on the sides of the fuselage, and an outer covering of three-ply tacked to the formers and struts completes the construction. There is no wire bracing whatever in this portion of the fuselage. The first and second formers carry the strong ash engine bearers, the third and fourth are placed in line with the front and rear wing spars respectively—the fourth former being in the centre of the passenger's cabin is, therefore, left open, *i.e.*, it has no cross members except at the top and bottom. The fifth former serves as the end wall of the cabin, and between this and the fourth former is what might be termed a false former of light construction. The engine and fuel compartments have a single outer covering of three-ply, whilst the cabin portion has a double (inner and outer) covering. Three separate compartments or bulkheads are thus formed, the first being the "engine room," the second housing the large fuel tanks (six hours), and the third the passenger's cabin.

The latter is exceptionally roomy, measuring roughly 3 ft. in width, 8 ft. in



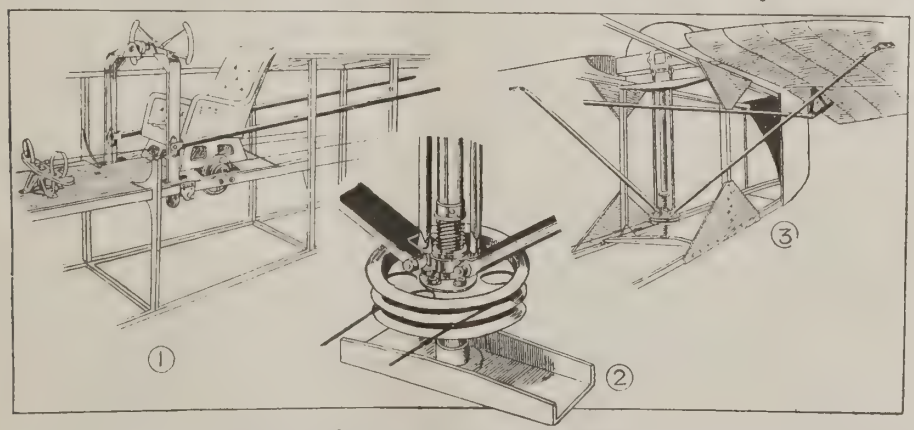
Three-quarter front view of the B. A. T. 4-seater biplane

length, and just over 5 ft. in height. For passenger work, therefore, it affords great possibilities in the way of a luxuriously fitted-up and comfortable "saloon," with armchairs, tables, etc., in the present model there will be three armchairs and one folding seat, the latter, being opposite the door, which is at the rear of the cabin on the port side. Windows, with sliding Triplex glass, are cut in the sides of the cabin between the top and middle longerons, three on the starboard, and two on the port sides, whilst portholes will also be let into the turtle-deck roof at various points.



The cabin is equally suitable for mail work, and one can easily visualize this roomy compartment fitted up with pigeon-holes and benches, with a P.O. clerk busy at work sorting out letters, depositing them in their respective parachute bags, and dropping them overboard above their destination!

Aft of the cabin the fuselage is a girder of six bays, the first set of cross members being built up on the lines of the formers in the front half, as shown by No. 6 in the accompanying diagram. The other cross members are of the usual H-section, reinforced here and there by three-ply. With the exception of the last one, all the bays are braced with flat "streamline" steel cable; the last bay, however, has H-section diagonal struts and a three-ply covering. The pilot and control are located in the second bay, being supported fairly high up in the fuselage by two channel-section bearers on a three-ply floor. This rear portion of the fuselage is covered with fabric, except for the top, which has a three-ply turtle-deck. At the end of the third bay a steel tube passes across the fuselage through the lower ends of the vertical struts and projects a few inches on either side of the fuselage, thus providing a means for lifting the tail.

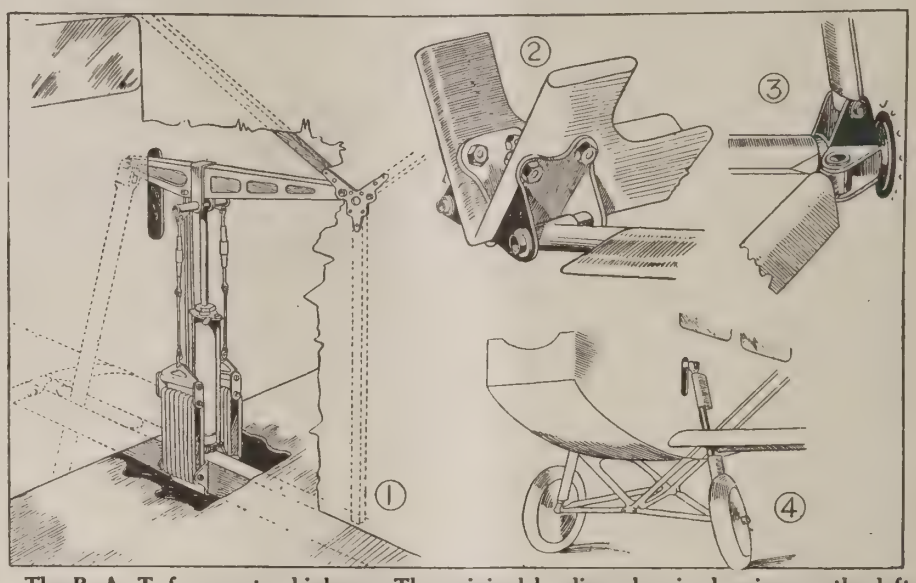


The control is similar to the well-known "Dep." type, and consists of a wooden bridge pivoted to the previously mentioned bearers, carrying at its upper end the peculiar shaped "wheel" shown in one of the accompanying sketches. The elevators are operated positively by flat elliptical-section steel tubes, anchored at the forward ends to each side member of the bridge and connected at the rear to a strong single crank arm on the underside of each elevator flap. The aileron cables are led from the "wheel" over pulleys down the arms of the bridge to its base, whence they pass down to pulleys at the end of the cabin, just below the floor, under which they proceed to pulleys at a point just behind the front spar, where they are taken at right angles out of the fuselage through the lower plane to pulleys just beyond the outer interplane

Some constructional details of the B. A. T. four-seater biplane. On the left is the top plane attachment to the center section which is similar to those on the lower plane. In the center is a sketch of the steerable tail skid, and on the right is the strong but simple elevator crank

Above—The Water Radiator. Below—Radiator, filter, and fuel cap on the B. A. T. four seater biplane

The B. A. T. four-seater biplane—On the left, a sketch of the pilot's seat and control. On the right, the tail plane trimming gear, and inset, a detail of the screw gear of the latter



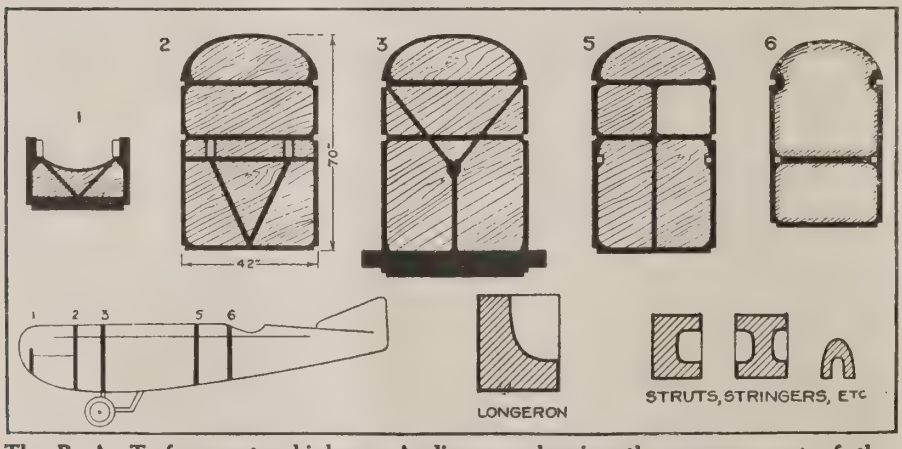
struts. For here they pass out underneath the plane to cranks on the underside of the ailerons. The upper and lower ailerons are connected by steel cables, and the upper port and starboard ailerons are connected by a balance cable passing along inside the top plane. The rudder is operated direct by cables from a wooden foot-bar reinforced by sheet aluminum. Except for the aileron and rudder cables, all other control connections (engine, etc.), are steel or aluminum tubing—all shafts of cranks being mounted in ball bearings. The engine control rods (aluminuium) pass out from the cockpit through the turtle-deck and pass along on top of the latter to the "engine room." The switches are mounted outside the cockpit on the port side of the turtle-deck.

The angle of incidence of the tail plane can be adjusted whilst in flight by means of an aluminium wheel, at the pilot's left just below the seat, which operates through cables a screw and nut gear as shown in one of the accompanying sketches. The rear spar of the tail plan is hinged, so that the front of the tail is raised or lowered.

The main planes are of equal span, and are made of four interchangeable sections and a centre section to which the upper planes are attached. The centre section is mounted on two pairs of steel struts sloping outwards from formers three and four. Each pair of struts is laterally cross-braced by flat, oval section steel wires. A steel strip also connects the lower ends of the port and starboard struts and takes some of the load from the landing wires, which are taken from the base of the centre section struts to the lower plane. The lower plane is attached to short centre sections projecting from the sides of the fuselage, giving the same overall width as the top centre section. The centre section spars pass through the fuselage and are built integral with the respective former. In the front one the ends are cut short for the passage of the chassis strut, which passes through a welded steel box which replaces the cut-away portion of the spar. The end of this box also forms the wing attachchent fitting which is the same on all spars, and which is shown in one of the illustrations. Constructionally, the planes present nothing unusual, except perhaps in the tips. They have what might be described as a lateral washout, that is, the under surface curves up to meet the top surface which is level right to the tip. The spars of laminated I-section, solid where necessary, and the ribs are built up as usual of spruce webs and flanges. Each wing has four bays, the compression members being of the box type, and located at the interplane struts with a third in between. The internal bracing is of piano wire, the outer bay having a diagonal strut. Top and bottom planes are sepa-

rated by two pairs of tubular steel struts aside, and the whole of the external bracing is by streamline wire. Ailerons are fitted to both top and bottom planes, and these taper from root to tip.

The tail plane is of high aspect ratio, and has a symmetrical streamline section. It is built in one piece and mounted just above the top longerons. The rudder is balanced, the vertical fin being cut away to receive the balanced portion. By far and away the most interesting feature of the F.K. 26 is the landing chassis and its shock-absorbing arrangement. As may be seen from our illustrations, the wheels are each hinged by two stub axles to a cabane, consisting of a pair of V struts connected by a longitudinal member, mounted on the bottom of the fuselage. The front pair of these stub axles lies at right angles to longitudinal axis of the machine, and the other pair is inclined back to the rear V of the cabane. Extending upwards from each outer extremity of these "axle-Vee" is a steel tube which is connected at its upper extremity to the end of a lever projecting through the sides of the fuselage and hinged at its other end to the centre of the fuselage-former. Near the outer extremity of this lever is a lug from which connection is made to an oleo shock-absorber and to a pair of ordinary elastic shock-absorbers. There is a similar gear on each side of the fuselage. Thus, on landing, as the wheels rise, they also lift the levers against the action, first, of the oleo, and then of the elastic absorbers. The levers above referred to are of welded steel box construction, and it will be noticed that the wheels are splayed, so that when in flight they point inwards in a down direction, and when on the point of landing they are more or less horizontal, and when the machine is at rest, with its full weight on the wheels, they point inwards in an up direction. The general arrangement and construction of this landing gear is clearly shown in our illustrations.



The B. A. T. four-seater biplane—The original landing chassis showing on the left the shock-absorbing gear, and on the right the hinged stub axles and hub at the top, and below, a general view of the chassis

Another interesting feature is in the tail skid. This is of the steerable type, and consists of a short steel-shod wooden skid anchored at its upper end to a tube passing up through, and secured to, the rudder post. The "head" of the skid is connected to a lug some distance up the rudder post by two telescopic tubes passing up through the rudder, and containing a steel spring, which absorbs the shocks on striking the ground.

The engine is a Rolls-Royce Eagle, VIII, mounted, as previously stated, on two strong ash bearers between the first and second formers. It is enclosed by an aluminium bonnet, whilst a "manhole" in the bottom of the fuselage gives access to the engine from underneath.

The cooling system is very efficiently carried out, and is made up of two long streamline-shaped "honeycomb" radiators, mounted one on each side of the fuselage. They are conected top and bottom to two tanks within the fuselage, as indicated in one of the accompanying sketches. On the back of each radiator is a shutter, which can be opened or closed from the pilot's cockpit. A neat and simple oil-cooling radiator is also fitted; this is shown in one of our sketches, and consists of an extension of the oil tank next to the engine projecting through the starboard side of the fuselage, and having a series of tubes passing through it from front to rear. This projection also carries the oil filter and filling-cup. As pretviously mentioned, the fuel tanks are located in the compartment between the engine and the cabin. Petrol is delivered direct from the main tank to the carburetor through the agency of two windmill pumps mounted above the turtle-deck and the tanks. There is, however, a small service tank, for emergency, let into the leading edge of the top centre section.

The B. A. T. four-seater biplane—A diagram showing the arrangement of the formers in the fuselage

The estimated maximum speed of the B.A.T. F.K. 26 is 110 m.p.h., whilst the landing speed is about 40 m.p.h.

Book Reviews

Applied Mechanics, Vol. II, *by Charles E. Fuller and William A. Johnston.* This volume has been prepared primarily for the use of students in the Departments of Engineering in the Massachusetts Institute of Technology and is intended to cover the fundamentals of the subject in as far as they may be required in subsequent work in structural and machine design and in the ordinary problems of engineering practice. As preparation a student should have a knowledge of Differential and Integral Calculus, the principles of Statics and Dynamics, and the methods of determining centers of gravity and moments of inertia of areas of solids. Considerable attention has been given to the logical development of the subject and care has been taken to point out the limitations of the different theories; emphasis being laid on the divergence of the conditions met in practice from the ideal conditions, under which the theoretical formulas are deduced, and on modifications necessary, or advisable when the formulas are used under ordinary working conditions. Some of the subjects treated of in this invaluable publication are physical properties, materials, analysis of stresses and strain, unform stresses and uniformly varying stresses in beams, deflection of beams, continuous beams, combined stresses, general theory of flexure, columns, shafting and springs, curved bars, etc. Price is $4.00, post paid.

Gas, Gasoline and Oil Engines, *by John B. Rathbun.* A simple, practical and comprehensive book on the construction, operation and repair of all kinds of engines, dealing with the various parts in detail and the various types of engines and also the use of different kinds of fuel. This volume contains a valuable and complete gas engine glossary. Price $1.35, post paid.

Gas Engine Troubles and Installation with Trouble Charts, *by Rathbun.* A book that shows you how to install, operate and make immediate repairs and adjustments on all types of gas, gasoline and oil engines. Complete and indexed trouble chart for ready reference included therein. Profusely illustrated. Price is $1.35, post paid. Procurable at the Aeronautic Library, Inc., 299 Madison Avenue, New York City.

THE DESIGN OF AEROPLANE FITTINGS

By E. S. BRADFIELD

Formerly of Naval Aircraft Factory

IN the testing of complete aeroplane parts, such as fuselages, tail units, wings, etc., it is shown very clearly that failure usually took place in the metal fittings or their attachment to wooden members rather than in the main parts, such as beams, longerons or wires.

In starting the design of aeroplane parts, it is first necessary to have a stress diagram showing the direction and magnitude of the forces acting on the principal parts. From this diagram it is easy to pick out the forces acting at a single point, where a metal fitting is used to connect beams, struts and wires.

After finding the forces acting it is next necessary to resolve them into components acting parallel and perpendicular to the main part, as a wing beam. Having done this, the finding of the dimensions and design of the metal fittings is easily determined by the following charts.

A chart for determining the thickness of metal required in wire attachment lugs and also in the fitting is shown in Figure 1. The figures at the left bottom are the forces acting in pounds. The left hand graphs are the bearing strengths of metal used. The right hand graphs are the bolt sizes, and the bottom right hand figures are the metal thicknesses. Having the force acting we go up vertically to the bearing strength, then horizontally to the bolt size, and down to the thickness required.

Figure 2 is a chart for determining the bolt size. At the left is the force acting parallel to the grain of the wood. The graphs are the bolt sizes, and at the bottom is the wood thickness for both spruce and ash, when stressed at 3,500 to 5,500 pounds per square inch respectively.

Having the force acting and the thickness of the wood, we find their intersection, and the bolt size that this is on or below is the proper size of bolt.

A chart for finding the area of metal fitting required against the wood is given in Figure 3. At the left is force acting perpendicular to the grain of the wood, and at the bottom are the areas required both for spruce and ash when stressed at 450 and 1,150 pounds per square inch respectively. Having the force and going horizontally to the datum line and then down, we find the area required on the wood.

Figure 4 is for determining the width of metal required in a wire lug or other part under tension. At the bottom right is the force acting. The right hand graphs are the tensile strengths of the metal used, and the left hand graphs the width of metal, and the left bottom figures are the thicknesses.

Having the force, tensile strength and thickness, we go from the force up to the strength, then horizontally until we intersect the thickness and reading the graphs get the width required.

Below is a table, Figure 5, giving the strength of 3½ per cent nickel steel bolts, both in tension and single shear.

Bolt Size	Strength in Single Shear	Tensile Strength at Th'ds
⅛	1000	800
5/32 No. 8	1500	1300
3/16 No. 10	2150	1800
7/32 No. 12	3000	2500
¼	4000	3400
5/16	6100	5400
⅜	8800	7700
7/16	118800	10500
½	15500	13500

Figure 5

Figure 6 is a table that gives the minimum thickness that may be used for different areas of flat metal to have the necessary stiffness. The force is considered as acting at the center of area. When ribs or flanges are used to stiffen the part this data does not apply, and a calculation or test must be made to determine whether or not the fitting is stiff enough.

Thickness B. W. G.-In.	Area.
16	3½
14	5
12	8
⅛	12

Figure 6

An example will now be given of the use of the above charts. Figure 7 shows the forces acting at the attachment of a drift strut to a wing beam, that is the actual force times

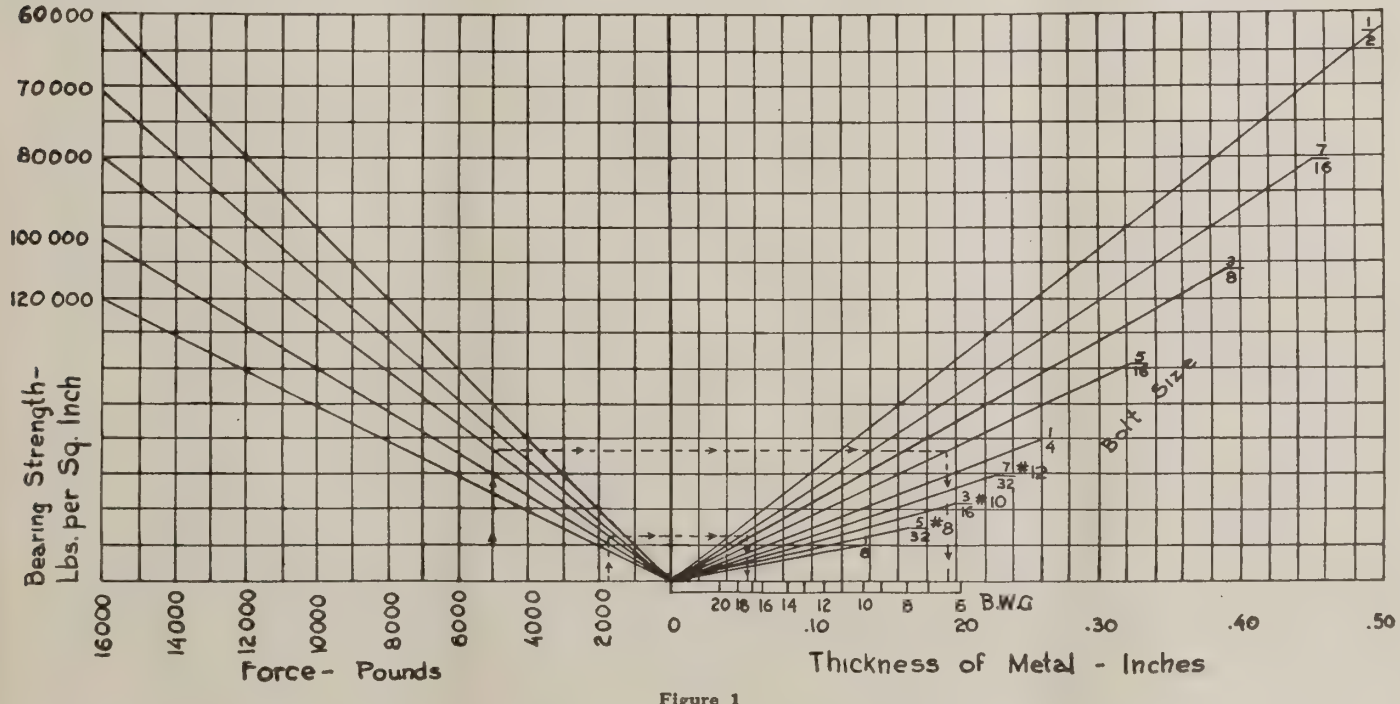


Figure 1

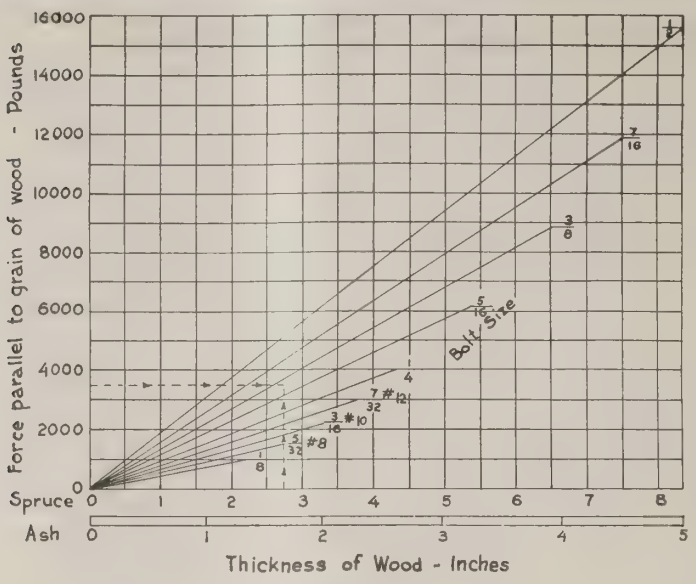

Figure 2

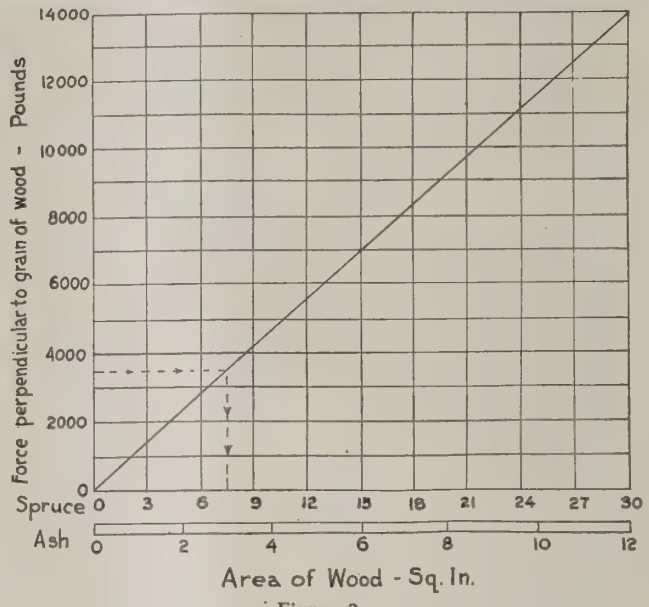

Figure 3

a suitable factor of safety. The beam is assumed 2¾ in. thick. It is first necessary to find the size of the bolts E and F. Experience has shown that in most cases the bolt size is determined by the area required on the wood to resist sliding of the fitting along the wing beam. As the fitting does not surround the beam, the bolts are effective for only half their length, or 2¾ in. in all for both bolts. The force is 3,500 pounds. Turning to Figure 2, we find that the minimum bolt size is ⅜ in.

The force acting on the strut B is 3,500 pounds, which is transmitted to the fitting and by it to the beam. Referring to Figure 3 we see that for a spruce beam the area of the fitting should be 7½ sq. in.

From Figure 6 we see that for this area No. 12 gage metal should be used to get the required stiffness. It is now necessary to find out if this is thick enough to transmit the force to each bolt, which is 1,750 pounds. Following out the data for 1,750 pounds, 80,000 pounds bearing strength and ⅜-in. bolt in Figure 1, we find that No. 17 gage metal would be thick enough, so we are well on the safe side, as from stiffness use has to be made of No. 12 gage. It is apparent that otherwise No. 17 gage would have been used.

From a study of Figure 7 it will be seen that the bolt E transmits some force to the washer W. As the fitting is of fairly heavy material, we shall assume that two-thirds of the

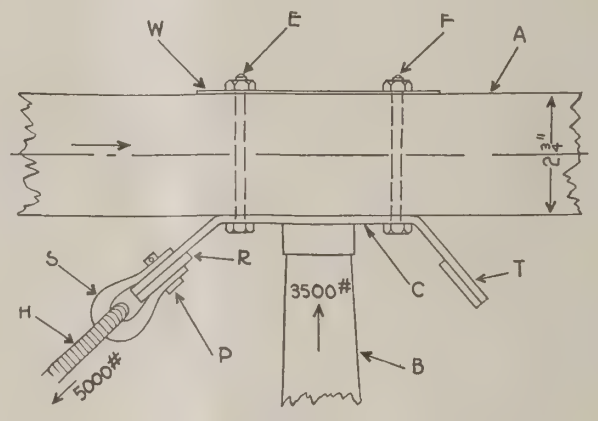

Figure 7

vertical component of the wire pull is transmitted to the washer W, or 2,500 pounds.

From Figure 3 we see that this requires an area of 5 sq. in. under the bolt E, and from Figure 6 we find that No. 14

(*Concluded on page* 1184)

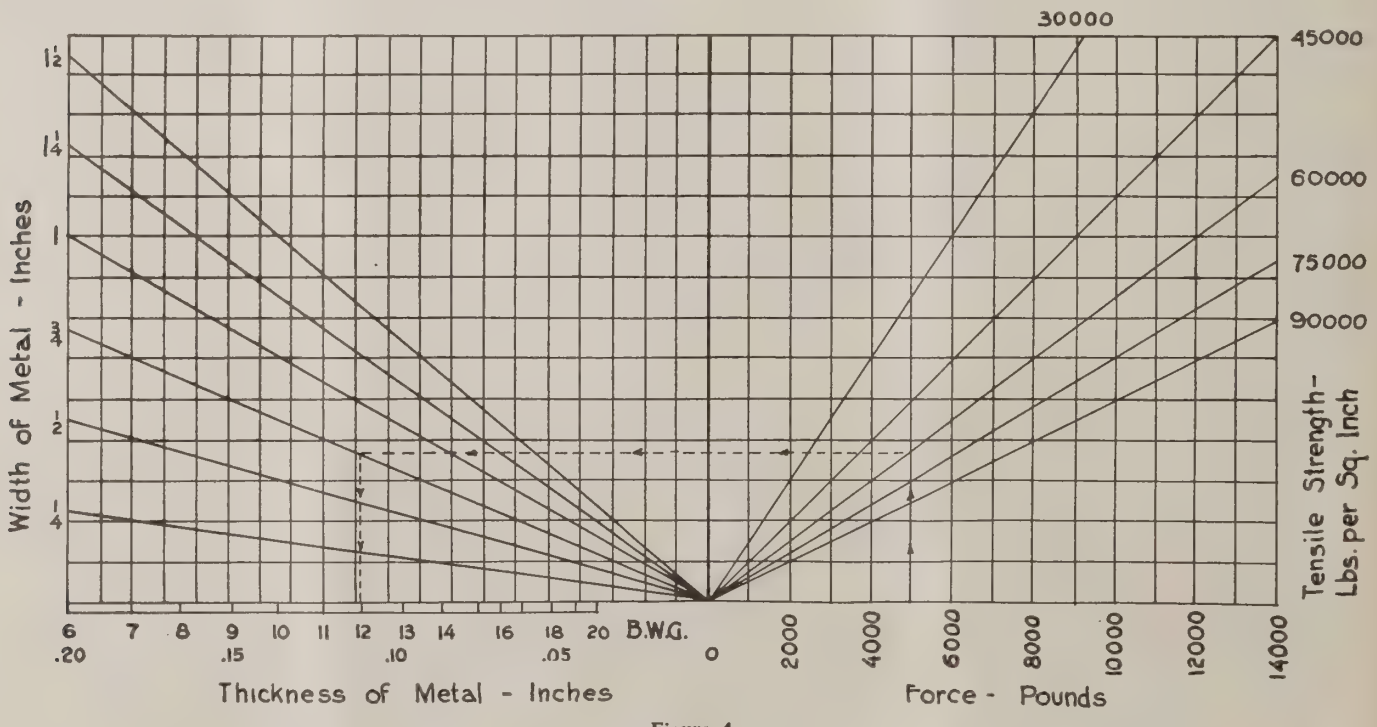

Figure 4

DEVELOPMENT OF AN AEROPLANE SHOCK RECORDER

By A. F. ZAHM, Ph. D.

Bureau of Construction and Repair, Navy Department*

TO meet the current needs of the aeroplane designing staff of the U. S. Navy, an aeroplane accelerometer was developed for measuring the sudden loads and shocks encountered in flying and landing. An elaborate instrument of precision was not called for, but rather a device whose records could be obtained easily and read directly. For the scale drawings and early tests of the design here described the writer is indebted to his assistant, Mr. L. Crook, who first calibrated the accelerometer, then used it on a flying boat to measure landing shocks.

Fig. 1 pictures the instrument in course of development. It consists of many vertical styluses, or pointed rods, supported individually by springs and recording on a single chronograph drum over which passes a continuous sheet of sensitized paper. For measuring upward accelerations the rods, which are all of the same mass, are pressed upward against stops by springs of graded intensity, while their pointed lower ends, or needles, are held within a few thousandths of an inch of the chronograph drum. When acceleration occurs a certain number of styluses begin to record instantly, as the intensity of the force overcomes in succession stronger and stronger springs.

When preparing the instrument for any proposed measurement one sets the springs so as to meet any probable accelerations that will have to be recorded. By means of the sliding sleeves shown in the photograph the force of the springs can be adjusted so as to equal any multiple of the weight of a rod. To this end one applies in succession to each stylus, by contact with a weighing scales, forces which are multiples or fractions of the whole fixed weight of the rod plus half the weight of the spring, while the springs are adjusted so as barely to support the rod against the stop. A single rod of brass weighs about 1¾ ounces, being 9/32 inch diameter by 5 inches long.

To prevent the needle from scratching or puncturing the paper it is cushioned against a spiral spring inside the holder, or vertical rod, within which it can otherwise slide freely. The needle at its middle is provided with a shoulder abutting against the upper end of the small holding and adjusting screw. This screw can, by rotating, raise or lower the setting of the needle, and is securely fixed in place by the jam nut shown at the bottom of the rod. The needle is of brass or German silver, and makes a clear, fine mark on the chemically treated paper when the pressure is 3 per cent or more of the weight of the holder. One per cent of the weight would be sufficient pressure with styluses 50 per cent longer and thicker, for a test has shown that .05 ounce pressure of the needle causes a clear trace.

In the position and adjustment shown, the present instrument records only upward accelerations, but by inversion can, without further adjustment, record downward accelerations, provided account be taken of the reversed direction of gravity. Thus, if when upright, the stylus exerts on the stop a pressure nw, inverted it exerts $(n - 2)\ w$; and hence records accelerations $ng\ (n + 2)\ g$, w being its weight. Without inversion the instrument also records negative accelerations if the styluses be pressed downward against their stops. Also in its upright position the instrument records both positive and negative accelerations when the springs are set so that some styluses are pressed upward and others downward.

*Reprinted from the Franklin Institute Journal.

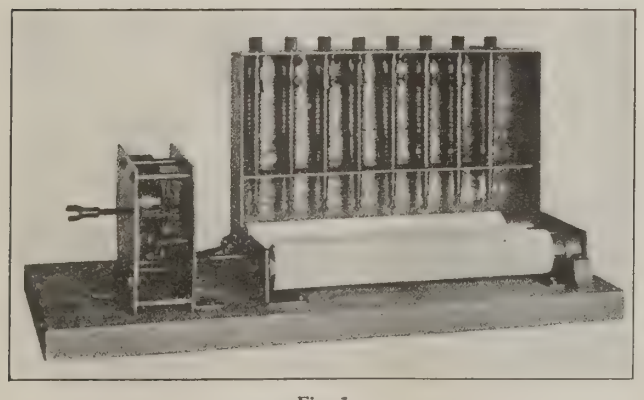

Fig. 1

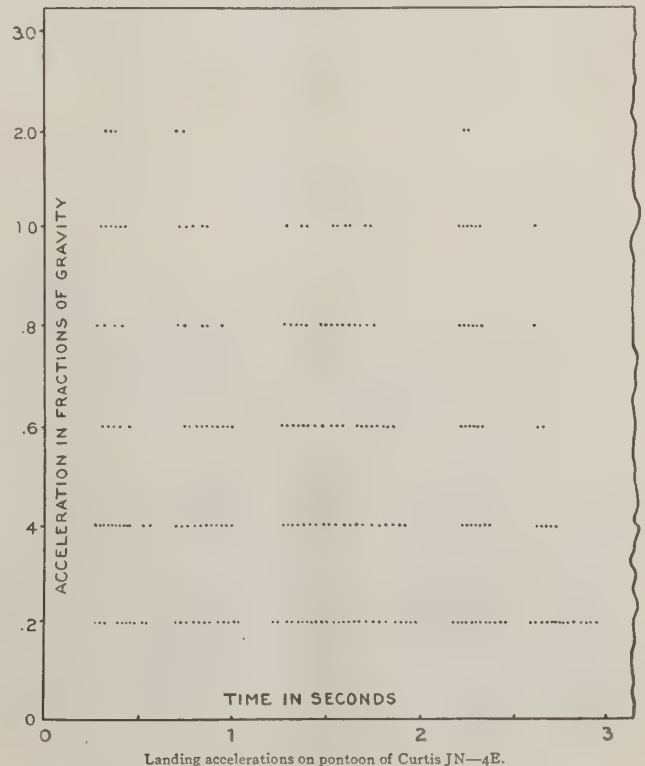
The special stylus shown on the right of the photograph is provided at its upper and lower ends with thin cantilever springs which prevent it from rubbing against the guide plates of the containing box, and at the same time hold the rod upward against its stop in the manner described for the spiral springs. An instrument with such cantilever, or anti-friction, springs could be used to measure horizontal as well as vertical acceleration.



In the form here shown the instrument is provided with 6 feet of paper driven by an alarm clock at the rate of 2 inches per second for such accelerations as are found in aeroplane experiments. This rapidity is essential in order to separate and clearly disclose landing shocks and structure vibrations; for it is usually the short hammer-blow shocks of a few hundredths of a second duration which most stress the under parts of an aeroplane in alighting on land or water.

In action the instrument appears to be fairly instantaneous and free from the oscillations found in a spring accelerometer whose recorder has a considerable displacement. Thus each needle records without interruption a definite continuous acceleration beyond a certain intensity, but instantly ceases recording when the acceleration falls below this amount. It can also simultaneously record long and short accelerations. For example, engine tremors superposed upon an air swell cause a needle to make a dotted trace, the length of the trace representing the duration of the swell beyond a certain intensity, and the distance between dots representing the period of the engine tremor. In fact, a known engine speed serves to standardize that of the paper, and a known paper speed that of the engine. The aggregate tracings of all the needles form a shaded diagram whose contour is a wavy line like that of a spring accelerometer.

An example of typical records taken on a seaplane is presented in Fig. 2 of this report. The farther stylus, which has its restraining spring adjusted to record upward accelerations of twice gravity, has made a few instantaneous traces separated by long blanks; the one set for two-tenths of gravity has made long traces with short blanks. Both records are dotted, showing engine tremors. Feeble accelerations were expected, otherwise a more suitable setting of the springs would have been made. They should have been graded to tenths in the region of two gravities.

Fig. 3 gives an acceleration record of an approximately

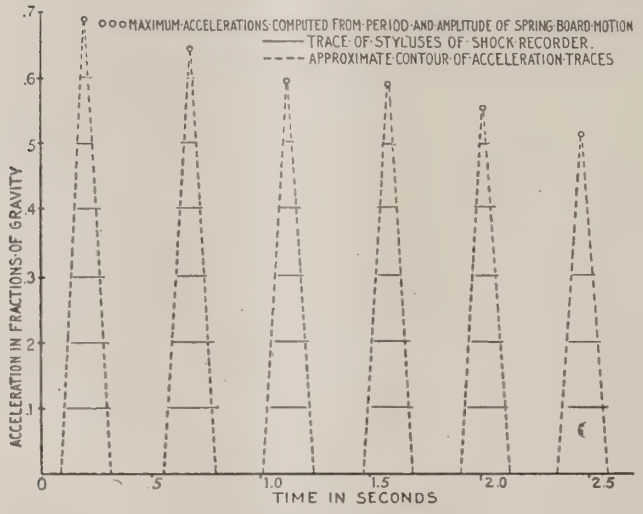


FIG. 2.

Landing accelerations on pontoon of Curtis JN—4E.

simple harmonic motion, somewhat damped, made with the instrument screwed to the end of a vertically vibrating spring-board clamped in a firm vise on a not very firm table, and with its styluses set only for positive accelerations. Plotted on the same diagram, as a line of small circles, are the simultaneous maximum accelerations of a needle inserted in the end of the spring-board and playing on a sheet of smoked paper moving steadily past it. The line of circles is a "damped" harmonic with a perceptible "overtone," and matches the damped acceleration trace taken simultaneously, all records being equally distant from the face of the vise. The actual tracing of the spring-board tip is given in Fig. 4, and the method of computing from this the maximum accelerations, which are indicated by the circles in Fig. 3, is developed in the following paragraph.

FIG. 3.

Calibration diagram for shock recorder.

Without rigorous precision the general equation to the vertical motion of the spring-board tracing point may be written

$$\ddot{s} + a\ddot{s}^2 + b\dot{s} + cs = o$$

in which s is the displacement, at any time t, from the point of rest under gravity, and $a\ddot{s}^2$, $b\dot{s}$, are retardations due to the air resistance and internal friction of the vibrating system. The maximum acceleration for any one vibration occurs when $s = o$, and may be written from the equation

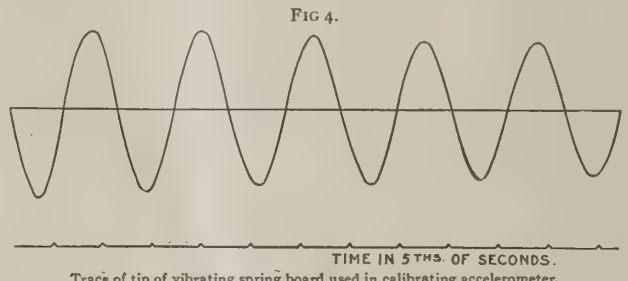
$$\ddot{s} + cs = \dot{o}.$$

It is

$$\ddot{s}_1 = -cs_1$$

in which s_1 is the momentary amplitude. Since the damping is small, s_1 can also, without material error, be written in the more familiar form

$$\ddot{s}_1 = -4\pi^2 n^2 s,$$



when n is the frequency. Now, since $\ddot{s}_1$ is approximately recorded by the acceleration styluses, and s_1, n, are found in the record of the vibration stylus, the one record can be checked with the other. This method was used in computing from the trace of the spring-board's motion, the accelerations indicated by circles in Fig. 3.

The acceleration records are fairly trustworthy as far as they go, but lack continuity, like the markings on a yardstick. To disclose accurately the maximum acceleration in any shock the adjustment of the springs must be close-graded. Thus, if a maximum acceleration of twice gravity be recorded by styluses graded to tenths of gravity, the greatest possible error is presumably one-tenth of gravity, or 5 per cent of the quantity recorded, while the probable error is 2½ per cent. Still closer estimates can be made by sketching in the contour of the traces. The free play of the styluses between their stops must, of course, be kept small.

Closer agreement between the two sets of superposed values in Fig. 3 would ensue if the clock ran uniformly; if the paper were uniformly thick, instead of being spliced; if the needle points were set 0.004 inch from the paper, instead of 0.012 inch; and if the styluses were given less play between their stops. These adjustments would be made in refining the instrument. But, even so, the records would not everywhere accurately disclose the acceleration, unless made with numerous styluses in close-graded adjustment. At one point, such as the third crest in Fig. 3, the record might be a mere dot, and hence indicate the acceleration truly; at another it might be a dash, leaving the true crest to be extrapolated. Numerous and close-graded styluses can, of course, be provided without much increase of cost or weight, if found desirable for special investigations.

For the immediate measurements in view it was thought unnecessary minutely to calibrate the shock recorder to a close-grade scale by experiment. Continuous recording instruments are in the market, such as the R A F photographic accelerometer, or in development, such as the Sperry mechanically recording accelerometer, and these may be had in time. The present instrument has served a passing need, and

FIG 4.

Trace of tip of vibrating spring board used in calibrating accelerometer.

may prove useful for disclosing hammer-blow shocks too sudden to be faithfully recorded by accelerometers of another type.

For a comprehensive field laboratory study of the accelerations throughout an aeroplane it may be well to measure simultaneously the shocks in the undercarriage, the body and the wings. This can be done either by placing individual recorders in those parts, and synchronizing them, or by placing shock receivers there and recording on a central chronograph. The present instrument, or a simpler one consisting of plane bar springs, could be used as a contact maker in various parts of an aeroplane to operate recording magnets at a central drum. Such an apparatus can easily be arranged, and may be expected to record with about the promptness of a ballistic or an astronomical chronograph.

For instantly indicating to the pilot the comparative stressing in his machine a number of simple bar-spring contact makers of graded strength can be coupled to a row of tiny electric lamps on the instrument board. These would brighten successively, and indicate by their various colors, positions, or markings, the degree of stress put upon his craft. A tentative instrument of this kind has been tried incidentally to the present study. Such cantilever styluses, or contact makers, have the simplicity and compactness of a row of piano keys, but are not preferred to the endwise-moving styluses because they are more affected by angular accelerations about their centers of gravity, or points thereabout, than are the rods used in the present instrument. Obviously the contact points could be used with a smaller gap than have the needles recording on paper.

Without its base the present instrument, whose case measures 9 inches by 6 inches by 1.5 inches, weighs 8 pounds, being made almost wholly of brass. By using aluminum, where practicable, the whole weight can be reduced to about 2 pounds. In this style the clock would form part of the case, and the whole could be screwed to the instrument board of an aeroplane.

NAVAL and MILITARY AERONAUTICS

Aero Squadrons on Duty at the Border

Washington, D. C.—According to a statement issued by the Director of the Air Service, leading ship No. 1, Flight "B" Eighth Aero Squadron, with Lieutenant Rex Stoner, flight commander, and Captain D. W. McNabb, commanding officer, as passenger, left Kelly Field for border duty at Laredo, Texas. Ships were flown in Vee formation entire distance of one hundred eighty miles.

The following units are now operating as border patrol flights:

McAllen, Texas—Headquarters and "A" Flight, 8th Aero Squadron.

Laredo, Texas—"B" Flight, 8th Aero Squadron.

Marfa, Texas—"A" Flight, 11th Aero Squadron.

El Paso, Texas—Headquarters 1st Bombardment Group.

Headquarters and "B" Flight, 11th Aero Squadron.

Headquarters and "B" Flight, 96th Aero Squadron.

Douglas, Ariz.—"A" Flight, 96th Aero Squadron.

Vacancies to Be Created by Legislation to Be Filled by Emergency Officers

Washington, D. C.—The War Department authorizes publication of the following information:

In filling such vacancies as may be created by future legislation reorganizing the Army, it is the policy of the War Department to select appointees from among persons who served as emergency officers during the war with Germany. Equal consideration will be given to all applications, whether the applicant is still in the service or necessarily has been discharged in the process of demobilization. No appointment will be made without a thorough and satisfactory final examination. All appointments will be provisional for a period of two years, during which time the appointment may be terminated should the provisional officer be found unsuitable for permanent retention in the service. Examinations will not, of course, be authorized until the enactment of legislation creating vacancies in the permanent military establishment.

A previous announcement of the War Department permitted the erroneous interpretation that preference would be given to emergency officers still in service in preference to discharged emergency officers.

Sales of Surplus Supplies

Washington, D. C.—The present status of surplus supplies is announced in a statement prepared by the Statistics Branch of the General Staff. The figures include all sales made up to August 15. The etsimated surplus on January 1, 1919, chargeable to the Department of Military Aeronautics was $85,000,000, of which $21,900,000 or 26 per cent. has been sold. $10,300 000 or 17 per cent. of the Bureau of Aircraft Production's $62,000,000 surplus has been sold.

Historical Branch of General Staff Seeks Photos of Army Activities

Washington, D. C.—The War Department authorizes publication of the following information:

There are scattered throughout the service many kodak films and plates, depicting the activities of the army in the United States, abroad and in our foreign possessions. This material covers a period of many years, extending back to dates before the activities of the photographic section of the Signal Corps commenced. These photos are of great value to the War Department for historical purposes and, incidentally, for the use of the recruiting service or other instrumentalities of the War Department, with a view to preserving these photos and the official use of them as the War Department desires, the Adjutant-General requests co-operation of all officers in the service. Films, plates and prints depicting activities of the army should be forwarded to the Historical Branch, War Plans Division, General Staff, with such descriptive matter as will identify the photos as to personnel, military unit, place and date.

Aviation Camp to Be Established in Arizona By Air Service

Douglas, Ariz.—According to a statement appearing in the local press, it is stated that a permanent aviation camp is to be constructed east of Camp Harry J. Jones. The decision is said to have been reached by a board of officers examining possible sites.

Thirty-five buildings will be constructed. In addition to the enlisted personnel, it is said about fifty officers, including flyers and ground forces, will be stationed at the field.

Aviation Construction Work in U. S. Only 1 Per Cent of Army's Total

Of the $818,000,000 expended by the army for construction purposes, it is stated that only $8,000,000, or 1 per cent, was used on aviation and signal corps projects.

Insignia for Naval Aviators, Student Naval Aviators and Flying Mechanicians

Washington, D. C.—Acting Secretary Roosevelt authorizes the following:

The Navy Department has approved the change of naval aviator device as follows:

The present gold pin with double wings based on the shield and anchor will be worn only on wash summer uniforms. The winter uniforms will carry a similar device of gold embroidery. Provision has been made by the new regulation which designates student naval aviators and flying mechanicians. The student wears a pin similar to that of the graduate aviator, with the exception that one wing is removed, leaving a device similar to that worn by observers abroad. Regular members of seaplane flight crews among the enlisted men will wear a pin similar to that of the student naval aviator, except that it shall be of silver.

This change is made with the belief that there should be a distinctive insignia for the graduate and student naval aviators, and further that the flying mechanician should also be entitled to wear some mark of distinction.

New Reserve Military Aviators Named

Washington, D. C.—The following-named officers, having completed the required tests, are rated as Reserve Military Aviators, to be effective from the date set after their respective names: Captain Roy N. Francis, June 10, 1917; Second Lieutenant John M. Coleman, July 13, 1919; Captain Herbert G. Knight, July 24, 1919; First Lieutenant Francis T. Murphy, July 24, 1919; Second Lieutenant Verne M. Monticue, July 24, 1919; Second Lieutenant Alfred L. Coe, July 24, 1919.

12,000 Tons of Air Service Property to Be Returned from A.E.F.

Washington, D. C.—According to a statement from the Statistics Branch of the General Staff, there remain 12,830 short tons of Air Service property to be returned from A. E. F. This is 7.2 per cent of the total army equipment still overseas.

A French S.E.A. two seater biplane which climbs 17,000 feet in 21 minutes and has a speed of 129 miles an hour at 6,500 feet

FOREIGN NEWS

Air-Cooled Bristol Engine Tested

London, England.—A new British scout machine powered by a new type of Bristol engine received its preliminary tests recently. The engine develops 450 horsepower. It is of nine cylinder type and weighs but 636 pounds.

$320,000 in Prizes to Be Offered by British Government

London.—The British Government will offer prizes amounting to $320,000 for aerial competition, it was announced by an Air Force officer in the House of Commons.

100,000 Yen Prize for Japanese Cross Country Race

Tokio.—A cross country race for prizes totalling 100,000 yen ($50,000) over a course 1,200 miles long is taking place in Japan during the months of July and August, according to information recently received. The first prize is 30,000 yen, the second 20,000 yen and the third 10,000 yen. The route is from Kagoshima to Sapporo. The landing places and distances are as follows:

	By railway.	By air.
Kagoshima-Fukuoka	170 miles	130 miles
Fukuoka-Hiroshima	190 miles	142 miles
Hirosh.ma-Okayama	97 miles	75 miles
Okayama-Osaka	114 miles	86 miles
Osaka-Toyohashi	160 miles	120 miles
Tokyo-Sendai	215 miles	176 miles
Toyohashi-Tokyo	189 miles	142 miles
Sendai-Morioka	115 miles	85 miles
Morioka-Aomori	127 miles	95 miles
Aomori-Sapporo	200 miles	150 miles
Total	1,577 miles	1,201 miles

A specified test flight is required before the contestants can participate. Only Japanese aviators may compete.

Unique among the conditions is a 50 per cent deduction if the prize is won by a foreign-built 'plane and a 30 per cent increase in the prize if the machine is entirely of Japanese construction, with the exception of the magneto.

Compensation for accidents or injuries sustained during the contest will be made to all participants. Loans for purchase and construction of machines and for expenses will be advanced to any competent aviator.

Aerial Competition in Fortugal

Lisbon.—An aerial contest over a course from Lisbon to Oporto to Vianna to Lisbon is being organized as a test for the contemplated flight from Lisbon to Guinea.

Regular London-Paris Aero Passenger and Freight Service Started

London.—A new freight and passenger aeroplane service between London and Paris was inaugurated on August 25.

The aeroplane 4-A left London at 9:08 o'clock and returned at 2:45, completing the round trip in five and three-quarter hours. Two firms have started daily flights simultaneously, charging $75 to $100 single fare. Considering the advantages, these prices are not held to be exorbitant. Great hopes are held out that these fares will be reduced as operating conditions become better, and with bigger, better 'planes capable of carrying heavier loads.

These 'planes carry one ounce of mail for $1. As it is possible to send 5,000 words for this sum, the rate is considered cheap. Cable tolls to Paris average 5 cents a word, and the aeroplane men say they will soon be able to beat the cable. The manufacturers say they have plans for reducing the time between the two cities to one hour and that this may be realized in one year.

French Aviator Flies Twice Under Var Bridge

Nice, France.—Aviator Maucon, with a local newspaper reporter as a passenger, twice flew through the arch of the Var River bridge on August 24. The arch is 66 feet wide and 26 feet high.

New Zeppelin Passenger Carrier in Successful Test

Berlin.—A new Zeppelin airship, on its maiden trip from Friedrichshafen to Berlin, covered the 435 miles in a little more than six hours. The aircraft, which is named the Bodensee, attained a maximum speed of 74½ miles an hour.

The builders of the new type machine have discarded the familiar cigar shape of the old Zeppelins and adopted a conical outlined exterior. The Bodensee is 360 feet long and accommodates thirty-five passengers. The aircraft is to go into a daily service.

Twenty-one passengers, among them three women, made the initial trip.

1,000 Horsepower Aeroplane Engine Tested in England

Wolverhampton, Eng.—An experimental aeroplane engine developing between 900 and 1,000 horsepower was put under test here recently. The 12 cylinders are arranged "V" fashion and the weight is less than 2,000 pounds. Special aeroplanes are to be constructed for the engine.

Prizes Offered for Valve Design in Germany

The Society of German Aircraft Constructors, in order to standardize design and produce more efficient models has offered three prizes for gasoline valves for aircraft engines. A prize will be awarded for the best design of each of the following types: the ordinary trough type, the three-way type, and a three-way by-pass type.

The Third Annual Aeroshow at Taliedo

Milan.—The third Milan Aeroshow at the Taliedo Flying Ground consists of a series of highly interesting exhibits, consisting chiefly of war machines. The Milan-Venice dirigible ship is operating from the field. The journey is made at three times the speed of the railway at four times its cost. Lunch is included in the 300 lire fare.

No fewer than eighty flying machines are on exhibit, exclusive of lighter-than-air vessels. These eighty may be divided into sections of historic and modern war and peace craft, and a section that contains enemy machines. The Bergonzi "canneton," or young "canard," a biplane with Anzani 45 h.p. engine elevators in front, daring vertical and horizontal dihedrals to the planes, is a very radical design. Of interest in connection with instruction is the Gabardini tethered monoplane and his chief pilot's foot-controlled runabout (steered by the feet only), which are used to get pupils accustomed to the feel of things before going up and wasting an instructor's time.

A number of excellent motors are exhibited, including the Perfetti-Dolara 300 9-cyl. air-cooled rotary with cylinders parallel to and revolving round the crankshaft, which is to say parallel to and revolving round the longitudinal axis of the aeroplane, and in a line with the direction of flight of the machine. The cylinder heads face the blast of the displaced air much as a revolving cowl of a tractor screw seems to do, and the big ends of the piston rods appear to transmit rotary motion to a flywheel at right angles to the motor axis, that is in the normal position of a flywheel in respect of the propeller.

The Fiat biplane intended to cross the Atlantic is undergoing trials here.

Spanish Air Routes to Open Soon

Madrid—Regular mail and passenger service between Malaga and Melilla (Morocco), and between Barcelona, Alicante, Rabat (Morocco), and Tolouse are to be put in operation within the next few weeks.

Representatives of a French aerial transport corporation are visiting Seville to complete arrangements for a Paris-Bordeaus-Madrid-Seville-Algiers service.

Handley Page Service Between Damascus and Bagdad

Cairo, Egypt—A number of British officers have left here with a Handley Page biplane to inaugurate the Damascus-Bagdad air line. The distance is 500 miles, a part of which is over the Syrian Desert.

185,000 Aircraft Workers in France

Paris—Le Petit Parisien publishes figures concerning France's efforts to provide her flying corps with necessary materials.

In 1915 France built 3,400 aeroplanes, 7,552 in 1916, 22,751 in 1917, and 34,219 during the first nine months of 1918.

The aeroplane factories employed 12,650 workers on Jan. 1, 1915; 30,960 on Jan. 1, 1916; 68,920 on Jan. 1, 1917; 131,551 on Jan. 1, 1918, and 186,003 on Nov. 1, 1918.

A Larger Caproni Triplane

Rome, Italy—A larger and speedier Caproni triplane is described in news dispa ches emanating from Rome. It is powered by 5 Liberty or Rolls-Royce Eagle engines of 400 horsepower each, driving two tractor and three pusher propellors. The span is over 98 feet. The total length 52, the height 26. The lifting surface is 2,801.7 square feet; the weight empty 7 tons; loaded 12 tons.

The fuselage extends through the center wing. There is accommodation for eight passengers in the upper cabin and for twenty-two passengers below. A dressing room and a dining room is provided.

Fiat Doubles Capital

Turin—The capital of the Fiat Company has been increased from 100 million to 200 million liras at a special general meeting just held in Turin. This increase has been made by the creation of 500,000 shares of a nominal value of 200 liras each, to be offered in option to the present shareholders at par, at the rate of one new share for each share now held.

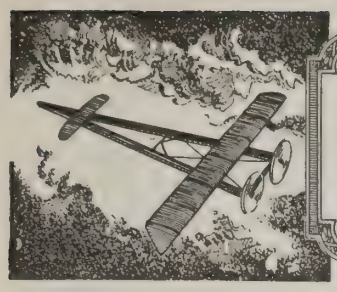
This increase in capital has been decided on in order to transform and modernize many of the present shops with a view to efficiency and economical output and the consequenty lowering of the price of cars.

Other work to be carried out comprises an increase in electrical power for the rolling mills and steel works held by the Fiat Company and producing exclusively for the Fiat motor factories. An increased capital is also required to enable the Company to take up interests either in Italy or abroad in order to prepare the automobile markets for commercial expansion.

Air Force Cadet College to Open February

The Air Ministry announces that a Royal Air Force Cadet College for the training of the permanent commissioned officers of the Royal Air Force will be opened next February.

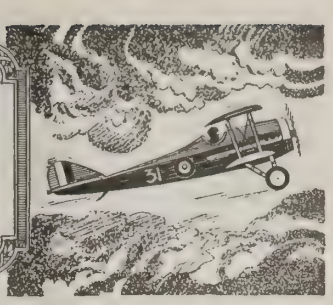
The place where the college is to be established will be announced shortly. The number of cadets to be admitted on the opening of the college will be 55.



Admission will be by competitive examination. The Air Council fully considered the alternative of admission by nomination combined with a qualifying literary examination.

Alliance Plane in Fast Flight from England to Spain

London—Leaving ts aerodrome at Action at 7 a.m. on July 31, "The Seabird," the aeroplane constructed to fly the Atlantic by the Alliance Aeroplane Co., flew to Madrid, making the journey of nearly 900 miles in seven and three-quarters hours. Capt. W. R. Curtice was the pilot, Mr. J. A. Peters, the designer of the machine was observer. The machine, which is fitted with a 450 h.p. Napier Aero engine, carried only 350 gallons of petrol, although the full capacity is 500 gallons. "The Seabird" carried a gold cup for presentation to the Queen of Spain as a memento of the occasion, also a letter from Princess Beatrice to Her Majesty, as well as a parcel of newspapers.



Aerial Mail for India

London—"A detailed scheme for an inland aerial postal service in India is being considered by the Government of India," says Mr. H. G. Perry, the "Daily Express" correspondent at Bombay. "A beginning will be made very shortly with a Bombay-Karachi seaplane service, in which the Governor of Bombay is taking a very lively interest. A service will probably be in full swing early next year. It will link up Delhi, Simla, Bombay, Calcutta, Karachi, Poona, Lahore and Madras. I understand that the Government has definitely decided on a State service.

ELEMENTARY AERONAUTICS and MODEL NOTES

By John F. McMahon

MANY readers of the Elementary Aeronautics page have written to the Model Editor asking for instructions and drawings on Compressed Air Motor models. To help these readers and others who might be interested in this type of power plant we are reproducing cuts that appeared last year in AERIAL AGE, as well as photographs of a compressed air model constructed by Mr. R. C. Hansen.

Compressed Air Motors complete or parts for building a compressed air motor can be purchased from the model aeroplane supply houses mentioned in our advertising columns.

The construction of a light weight racing model using this type of motor is very simple.

The general arrangement of the motor and tank assembly is shown at the right bottom of the cut.

The tank should be painted a dull black for effect.

The tank should be blown up by the use of a large foot pump, such as automobilists carry, to a pressure of about 150 pounds. This will take about one hundred strokes of an ordinary 1¼-inch diameter pump. A tire gauge will be needed to determine the proper pressure, as it is dangerous to put more than 150 pounds in the tank. The engine should be run under pressure a few times to work it in, keeping it well oiled up. A small fly-wheel can be put in place of the propeller for this preliminary test.

The construction of the model is such as to provide a support for the motor and tank and also to hold the wings and landing chassis. The engine is fastened to the end of the frame members by the use of two strips of brass bent around the cylinders and fastened with thread and glue.

The tank is fastened by drilling holes in the frame and by inserting the ends of the bolts projecting from the side of the tank to the nut. This makes the frame stronger and keeps it from twisting out of shape, at the same time being the neatest way to fasten in place.

The front landing chassis is made up of umbrella ribs. Where the ends are fastened to the frame the rib is heated red hot and when cool flattened out with a few strokes of a hammer and fastend with thread and glue.

The wheels are of cork or wood 2 in. in diameter. The tail skid is made up of steel wire as shown and is fastened as before.

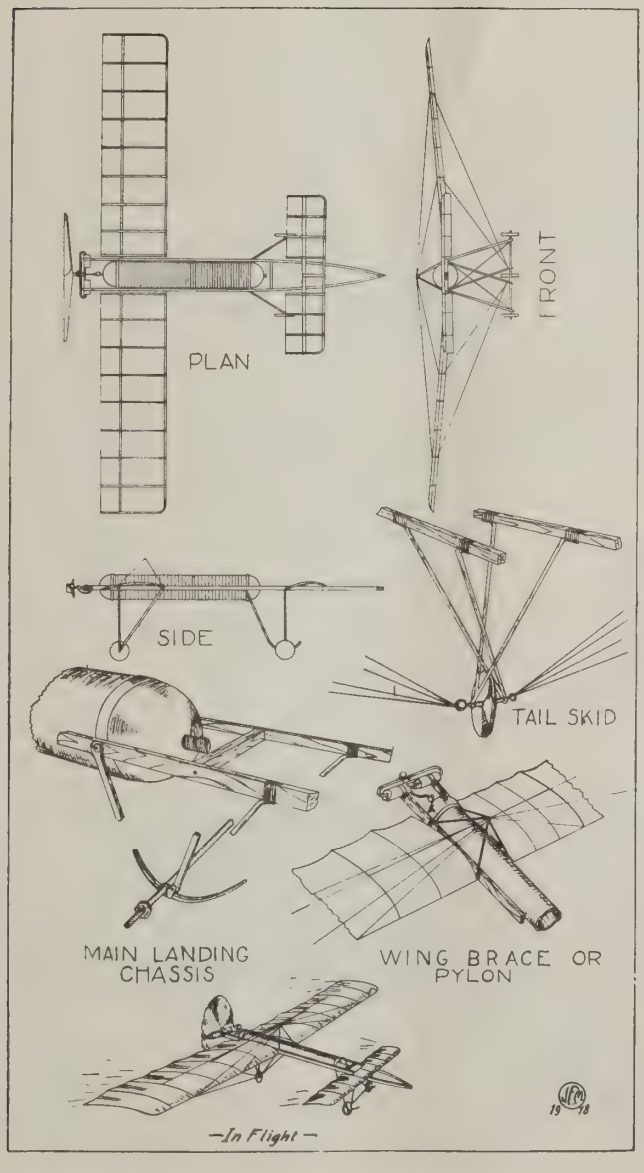
The rear wheel can be smaller in diameter and is also of cork or wood. The wings should be made as light as possible and are built up of bamboo strips and dowel stick 3/16 in. in diameter. They are of the single surface type, the silk being fastened with glue to the top surface and then doped.

The main spars of the wing should be planed to a half round section. The bamboo strips are fastened to the flat side of the spars. The trailing edge of the wings is formed by stretching strong linen thread from rib to rib as tight as possible. When the silk is fastened in place it will form what is known as a feathered edge and is very efficient.

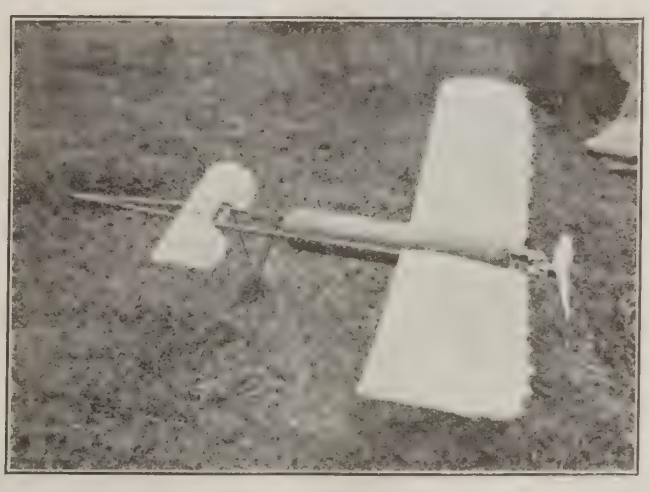
The main planes have a total spread of 54 x 8 in.; chord elevator is 18 x 4 in. When constructing the elevator the center rib runs to the rear spar only, to allow the plane to set at an angle of incidence to the line of flight.

The pylon or brace over the main planes is made of thin steel wire and fastened at the point shown in the drawings. When ready to fly the model be sure it is balanced properly. It is better to set the entering edge of the plane about 3 in. back of the center of gravity. The elevator can be moved back and forth according to the glide.

It is better to start the model from the ground rather than from the hand, as it is almost impossible to spin the propeller, turn on the air and throw the model at the same time without a chance of mishap.



The model builder can construct a sort of trigger arrangement for turning on the air, such as an arm soldered to the air "shut off" and a spring fastened to the tending to hold the valve open; to close, a sort of dog is fastened and when pressed by the finger it moves away, allowing the arm to swing back to the open position.



I might call attention to the size of the propeller. This should be from 12 to 16 in. in diameter, but the proper size can be determined by experiment.

The landing chassis must be made long enough to hold the model properly the correct distance from the ground to keep the propeller from striking when getting off.

Flights of compressed air models vary. Some engines I have made showed no leakage of air and the model would not fly as well when the leaking of the air could be heard distinctly. Of course, I do not say that the engine that leaks is the best, but I do believe that if the model builder is unfortunate enough not to make his apparatus air tight he can still get some reward for his work.

Some pretty scale models can be made powered with a compressed air motor. The famous Continental Aircraft Company's pusher is very well suited for this purpose. The tank, which must be made shorter and larger in diameter, takes the place of the body and resembles it a great deal. Drawings of the Continental machine appeared in a previous issue of AERIAL AGE.

A model powered with a compressed air motor constructed by R. C. Hansen of the Pacific Coast Model Aero Club

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

"No, girlie, that word is too reminiscent of life in the trenches."—*Manchester Evening Gazette.*

As the Trans-Atlantic Flying Boat Takes Off

On her first trip to Nantasket, little Bess remarked as she looked over the side of the flying boat: "Mama, they put too much bluing in this water."

Which reminds us of another tot who exclaimed on seeing the wake of the flying boat: "Oh, look, mother, the boat is losing all its soap."—*21st Century Chronicle.*

Just Before Flying Over

"So this is the first time you've ever seen the ocean," said her escort.

"Yes; the very first time."

"And what do you think of it?"

"Ah!" she sighed in ecstasy, "it smells just like oysters."—*Boston Transcript.*

The Pop and the Dirigible Hangar—Fontaine Fox in the N. Y. Globe

Long Range Archies

The mere man, desperately seeking for some dinner-table gossip—Shooting stars is the great sight this August.

The fairest (if not the brightest) of her sex—Oh, really, I'd no idea our anti-aircraft guns carried as far as that.—*Blighty.*

Seeing Is Hearing

Sergeant Major: "Now, Private Smith, you know very well none but officers and non-commissioned officers are allowed to walk across the grass."

Private Smith: "But, major, I've Captain Graham's oral orders to——"

Sergeant Major: "None of that, sir. Show me the captain's oral orders. Show 'em to me, sir."—*The Veteran.*

Sandy Was a Cagey Lad

"How was it you never let your mother know you'd won the V. C.?" "It wasna ma turrn tae write."—*Philadelphia Record.*

The Pilot's Farewell to the Old Machine

We've had many a flight together in fair and stormy weather,
But we've somehow always managed to pull through,
And we gave the Huns' Mercedes a replica of Hades,
And we've let the Albatross have something, too,
As we sent them on their death-dance,
Their fatal, fearful death-dance,
When we fought them up amongst the clouds of blue.

But I thought that we'd go under when they shot your struts asunder
On that morning not so very long ago,
But, thanks to God Almighty, we both of us got "Blighty,"
And we lived again to battle with the foe.
Oh! the nightmare of that nosedive,
That spinning spiral nosedive,
But we saved ourselves before we crashed below.

Now they say you're out of date and it's simply tempting Fate,
And to-morrow I've to fly a new machine
In all its pristine glory, which has yet to make its story,
Not like you, old 'bus, you veteran has-been,
With your mass of scars and scratches,
Your honored scars and scratches,
'Tis only you and I know what they mean!

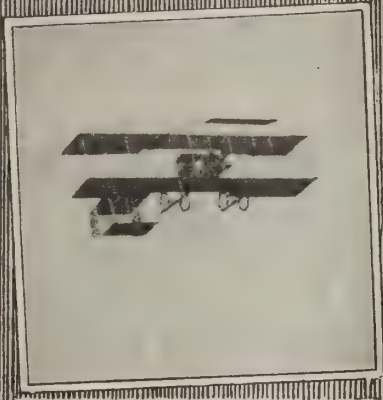
How I almost started sobbing when I heard your engine throbbing,
That embodiment of joyous life and soul!
That responded in a second and on whom I always reckoned,
And never once my confidence you stole.
They may give me any new 'bus,
A spanking, brilliant new 'bus,
But 'twill never be your equal to control.

So your flying days are ending, and I s'pose they'll soon be sending
You home again to mercilessly scrap,
But now the war is over and I live again in clover,
I'll dream, as I've come through without mishap,
For aye of you, my hero,
My own unbeaten hero,
And thank you dearly once again, old chap.

E. Duncan Doring, in Flying (London).

EVERY FIRST CLASS AEROPLANE REQUIRES A RETRACTABLE CHASSIS

THE EVOLUTION OF MARTIN AEROPLANES



HARVARD 1. DESIGNED, BUILT AND FLOWN BY MARTIN 1909

QUEEN-MARTIN THE FIRST TRACTOR BIPLANE IN AMERICA DESIGNED, BUILT AND FLOWN BY JAS. VERNON MARTIN 1911 SPEED 72 MILES PER HOUR.

MARTIN TRACTOR THE FIRST AEROPLANE IN ALASKA-DESIGNED, BUILT AND FLOWN BY MARTIN 1912.

BABY WHITE ALTERED, AND FLOWN BY MARTIN IN FIRST FLIGHT OVER LONDON, ENG. 1910

THE following aeroplane efficiency features, fully protected by domestic and foreign patents, are available to the aircraft industry.

The Retractable Chassis
The K-Bar Cellule Truss
Neutralized Symmetrical Wing End Ailerons
Aerodynamic Aeroplane Control
Shaft Drive Bomber Transmission
Aerofoil Type Fuselage
Rubber Strand Shock Absorbing Wheel
Shock Absorbing Rudder
Shock Absorbing Pontoon Supports

Engineering experts available for consultation. Contractor to United States Army and Navy.

EVERY FIRST CLASS AEROPLANE REQUIRES A RETRACTABLE CHASSIS

The Pomilios' latest data are given in this book

JUST OUT!

Sent for 10 days free examination

OF the many distinctive achievements in aeronautics in the past few years, few if any stand out so conspicuously as those of the POMILIOS of Italy.

In 1918, by special request of the United States Government, they came to this country to assist in an aircraft production program.

AIRPLANE DESIGN AND CONSTRUCTION

By OTTORINO POMILIO

403 pages, 6 x 9, illustrated, $5.00 net, postpaid

The publication of this book now—when the airplane industry is shifting from the design and construction of military types of craft to that of pleasure and commercial types—should go far toward replacing by scientific procedure many of the "cut and dry" methods now used.

This is the first book to be published in this country which presents in detail the application of aerodynamic research to practical airplane design and construction.

Examine it for 10 days FREE

AMERICAN PROPELLER & MFG. CO.

BALTIMORE, MARYLAND, U. S. A.

(*Concluded from page* 1176)

gage is correct to use for the washer. The tensile force on E is a maximum of 3,500 pounds, and from Figure 5 we find that a ⅜-in. bolt has a strength of 7,700 pounds, so that it is amply strong.

The wire H exerts a force of 5,000 pounds on the fitting. Turning to Figure 4, we see that if the tensile strength is 60,000 pounds, and the thickness No. 12 gage, the minimum width is ¾ in.

For the wire used we shall assume that the shackle S requires a pin P, which has a diameter of 5/16 in. It is apparent that a washer must be spot welded or brazed onto the fitting at this point to take the force acting. To determine the total thickness of metal we refer to Figure 1, and find the same to be approximately .195 in. The fitting is No. 12 gage, which leaves .087 for the washer, and as .083 is No. 14 gage, that is the metal we shall use for the washer.

The following facts from which to lay out this fitting have therefore been determined:

Plate C

Thickness	No. 12 gage
Area on wood	7½ sq. in.
Width at wire lugs	¾ in.

Washer R

Thickness	No. 12 gage

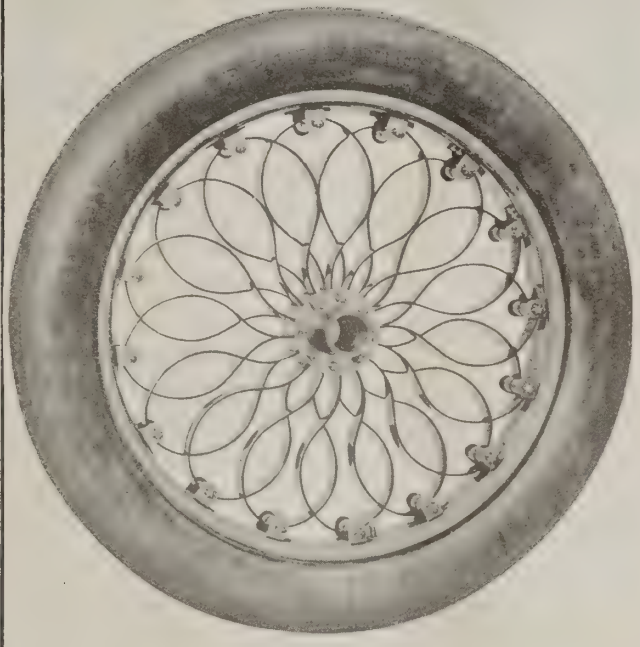
Washer W

Thickness	No. 14 gage
One-half area	.5 sq. in.

Bolts E and F

Diameter	⅜ in.

Pin P



Diameter	5/16 in.

From this data it is an easy matter to design these parts and be reasonably certain that no changes will be necessary due to weakness. Although as an extra precaution a sand load test of the complete machine should be made.

ATLAS WHEELS

Are daily gaining in favor with manufacturers and pilots of aircraft because:

They Absorb Shocks
They Are Stronger
They Are More Reliable

Standard Sizes Carried in Stock

Inquiries and orders will receive prompt attention

THE MACHINE YOU WILL EVENTUALLY FLY!!

MARYLAND PRESSED STEEL CO., (AIRCRAFT DEPT.)
Sales Manager, HARRY E. TUDOR 299 MADISON AVE., NEW YORK CITY

(*Continued from page* 1167)

(i) 3
(j) 3. Maximum total 45.

Behaviour afloat (*Rule* 22)
(a) 6
(b) 6
(c) 6. Maximum total 18.

High speed (*Rule* 5)
For each knot in excess of required minimum, ½ — No Maximum

Low speed (*Rule* 5)
For each knot below the required maximum, 1 — No Maximum

Mooring out test in fair weather (*Rule* 8*a*)
For each complete 5 minutes less than the hour allowed from the completion of the 24 hour period, to the moment when the machine leaves the water, 1 mark.

Mooring test in moderate weather (*Rule* 8*b*)
For behaviour of machine during test, maximum marks 5.
For condition of machine at end of test, maximum marks, 5.

Method of fitting parachute (*Rule* 24)
Maximum marks 5.

27. With reference to Rule 6, when carrying out alighting and getting off tests, machine will start with the load of petrol and oil specified and will be allowed to fly for 20 minutes. If they have not carried out their tests by the end of that period, they must alight and fill up again.

28. The type of propeller used on any machine must be the same for all the tests.

29. Full load will include:
Instruments as under:
Rev. counter
Aneriod
Air speed indicator
Compass
Watch
Turn indicator
Bearing plate
Sextant
Air pressure gauge (when necessary)
Oil pressure gauge (when necessary)
Radiator thermometer (when necessary)
Petrol and oil sufficient to fly 450 nautical miles at 1,000 feet.
In addition, a load of 1,000 lbs., to include passengers if carried and lifebelts and parachutes, but not including crew or any gear specified in Rules 8a and 13.

30. Petrol and oil for the tests and, as far as possible, accommodation (at owner's risk) for the machines will be supplied free by the Government.

31. The Judges shall have the right to disqualify any machine which is very seriously defective in any respect.

32. The Judges shall have the right to put up a service pilot to fly any of the machines, should they consider it desirable to do so at Government risk.
All tests will, however, be carried out by the entrant's pilot.

33. During or on completion of any flying test, if it is necessary to effect any repairs to the machine after alighting, it will be considered to have failed in that particular test.
This does not apply to cases where the machine is by the judges' instructions being flown by a pilot other than the entrant's pilot.

34. An entrant may enter more than one type of machine.

35. If a machine is wrecked during the competition, it may, at the discretion of the judges, be replaced by another, but the replacement machine must carry out the whole programme of tests.

36. The decision of the judges shall be final in all matters affecting the competition.

37. The Government does not accept any liability in respect of accidents during the competition, whether resulting in injury to personnel or damage to the machine (except as specified in Rule 32).

38. The Government reserves the right to adjourn the competition.

39. The Government reserves the right to withold any or all of the prizes if, in the opinion of the judges, no real advance on existing designs is shown.

40. The Government will, if the entrant agrees, buy the machine winning the first prize, the design to remain the property of the manufacturer. The maximum price payable under this head will be £8,000.

41. The following prizes are offered:

1st prize	£10,000
2nd prize	4,000
3rd prize	2,000

42. Entries to close December 31.

AEROPLANE INSURANCE

Merchants Fire Assurance Corporation of New York

This company issues policies covering aircraft against the following risks:

1—FIRE AND TRANSPORTATION
2—COLLISION (Damage sustained to the plane itself)
3—PROPERTY DAMAGE (Damage to the property of others)

Additional coverage may be had against loss by wind storm, cyclone or tornado.

We will be glad to discuss problems concerning aeronautic insurance.

Silver Star on Victory Ribbon Permitted for Only Certain Citations

Washington, D. C.—The War Department authorizes the publication of the following information:

It has been brought to the attention of the War Department that silver stars are being worn on Victory ribbons in some cases for citations which under army regulations are not sufficient authority for that decoration. The conditions which must be fulfilled for wear of these silver stars are set forth in paragraph 187, A. R., as amended by C. A. R., No. 85, and they are requirements of law. A silver star cannot be worn unless all three of the following conditions are fulfilled:

(a) The citation must be published in orders from headquarters of a force commanded by a general officer. A special citation certificate does not carry with it a silver star, neither does a citation in orders from headquarters of a force commanded by an officer below the grade of general officer, even though it may be appropriate command of a general officer.

(b) A silver star cannot be worn for any citation for which a Medal of Honor Distinguished Service Medal or Distinguished Service Cross was awarded.

(c) The citation must be for gallantry in action. This does not mean extraordinary individual heroism, but it does require that the acts for which awarded were performed in a gallant manner and under hostile fire, and the citation must distinctly show such to have been the case.

All officers and enlisted men wearing silver stars will present to the commanding officer of camp, post or station, for approval, copies of citation on which their claim is based. Cases which may be in doubt will be forwarded to the Adjutant General for decision. Copies of all approved citations of officers will be forwarded by the commanding officer, noting his approval, to the Adjutant General for file with officer's efficiency record; those of enlisted men will be filed with the individual's service record.

Commercial Air Routes Operating Throughout Germany

In spite of the disturbed internal conditions in Germany, a determined attempt is being made to establish aviation on a permanent commercial basis.

From reports recently published in *Flight* (London) it appears that a fairly large number of passenger services have been running for some time, mostly radiating from Berlin. Routes from the capital are in operation in Weimar, Frankfurt, Leipzig, Warnemunde, Hanover, Westphalia, Hamburg and Breslau. There are also services between Weimar and Frankfurt, Hamburg and Warnemunde, Leipzig and Weimar and Hanover and Westphalia.

The Berlin-Weimar route opened as early as February 5. The results for the period up to the end of the month showed that 120 flights took place, of which all but eighteen were successfully terminated. There were no accidents. The Berlin-Hamburg route was opened on March 1 and on this service also the results were considered satisfactory. In spite of bad weather and interruptions owing to trouble in Berlin a total of 108 flights, i. e., three to four per day, were accomplished and a total load of no less than 3,737 kilogrammes were carried. The average duration of each journey was 2 hours 11 minutes, with a record trip of 1 hour 15 minutes. This and other services were utilized for the carriage of mails, and on this route only 6.1 per cent. failed to get through owing to bad weather and had to complete the journey by train.

All these services are operated by the Deutsche Luft Rederie, a combine of various German aeronautical firms.

Return tickets are issued and are valid for a period of thirty days. Flying kit and motor transport to and from the aerodrome are provided and are covered by an inclusive charge of which the following are representative: Berlin-Hamburg: single, 450 marks; return, 700 marks. Berlin-Breslau: single, 500 marks; return, 750 marks. Berlin-Weimar: single, 450 marks. Serial tickets available for 10 flights on any of the routes operated by the combine are issued at 3,600 marks. These tickets are transferable, and work out at an average reduction of 20 per cent. Luggage is carried free of charge, but the total weight of passenger—who is carried at his own risk—and baggage combined must not exceed a certain limit. Mails and parcels are also carried by the company, which is working in conjunction with the Hamburg-Amerika line, through whose offices bookings may be effected.

Apparently the railway troubles have reacted favorably on aerial transport and a considerable increase of traffic has been caused. On the Berlin-Weimar route, which appears the most popular, the number of flights from February to the end of April was 538, while between Hamburg and Berlin from March 1 to the end of April there were 262 flights.

It is also of interest to note that a further fusion of interests of the various already existing commercial aviation companies is being organized under the direction of the Sablatnig Aircraft Factory and the Luftfah G.m.b.h.

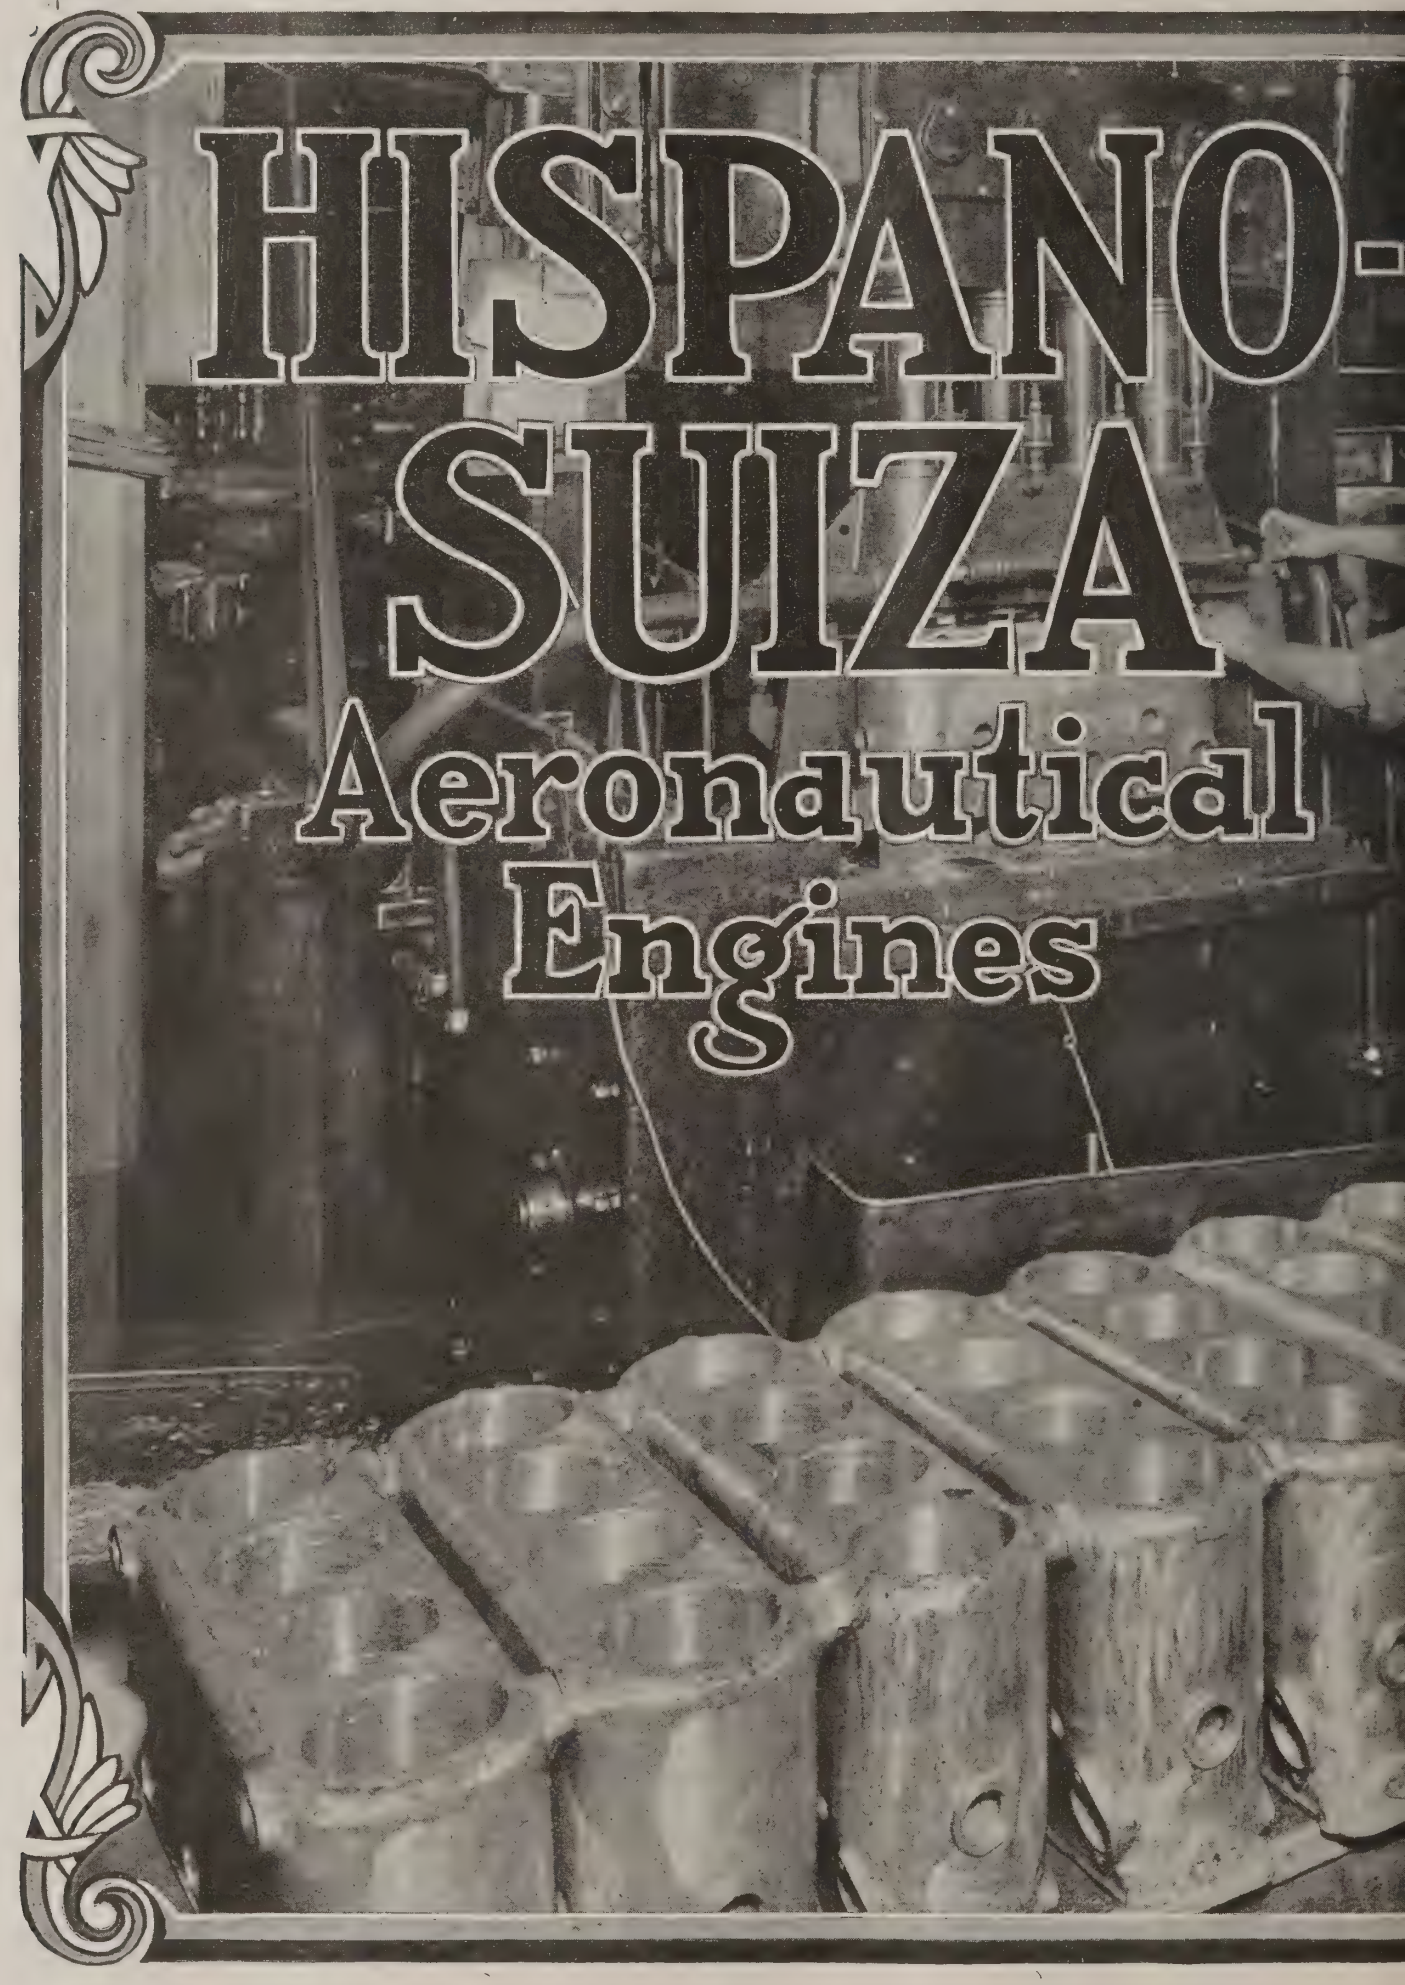
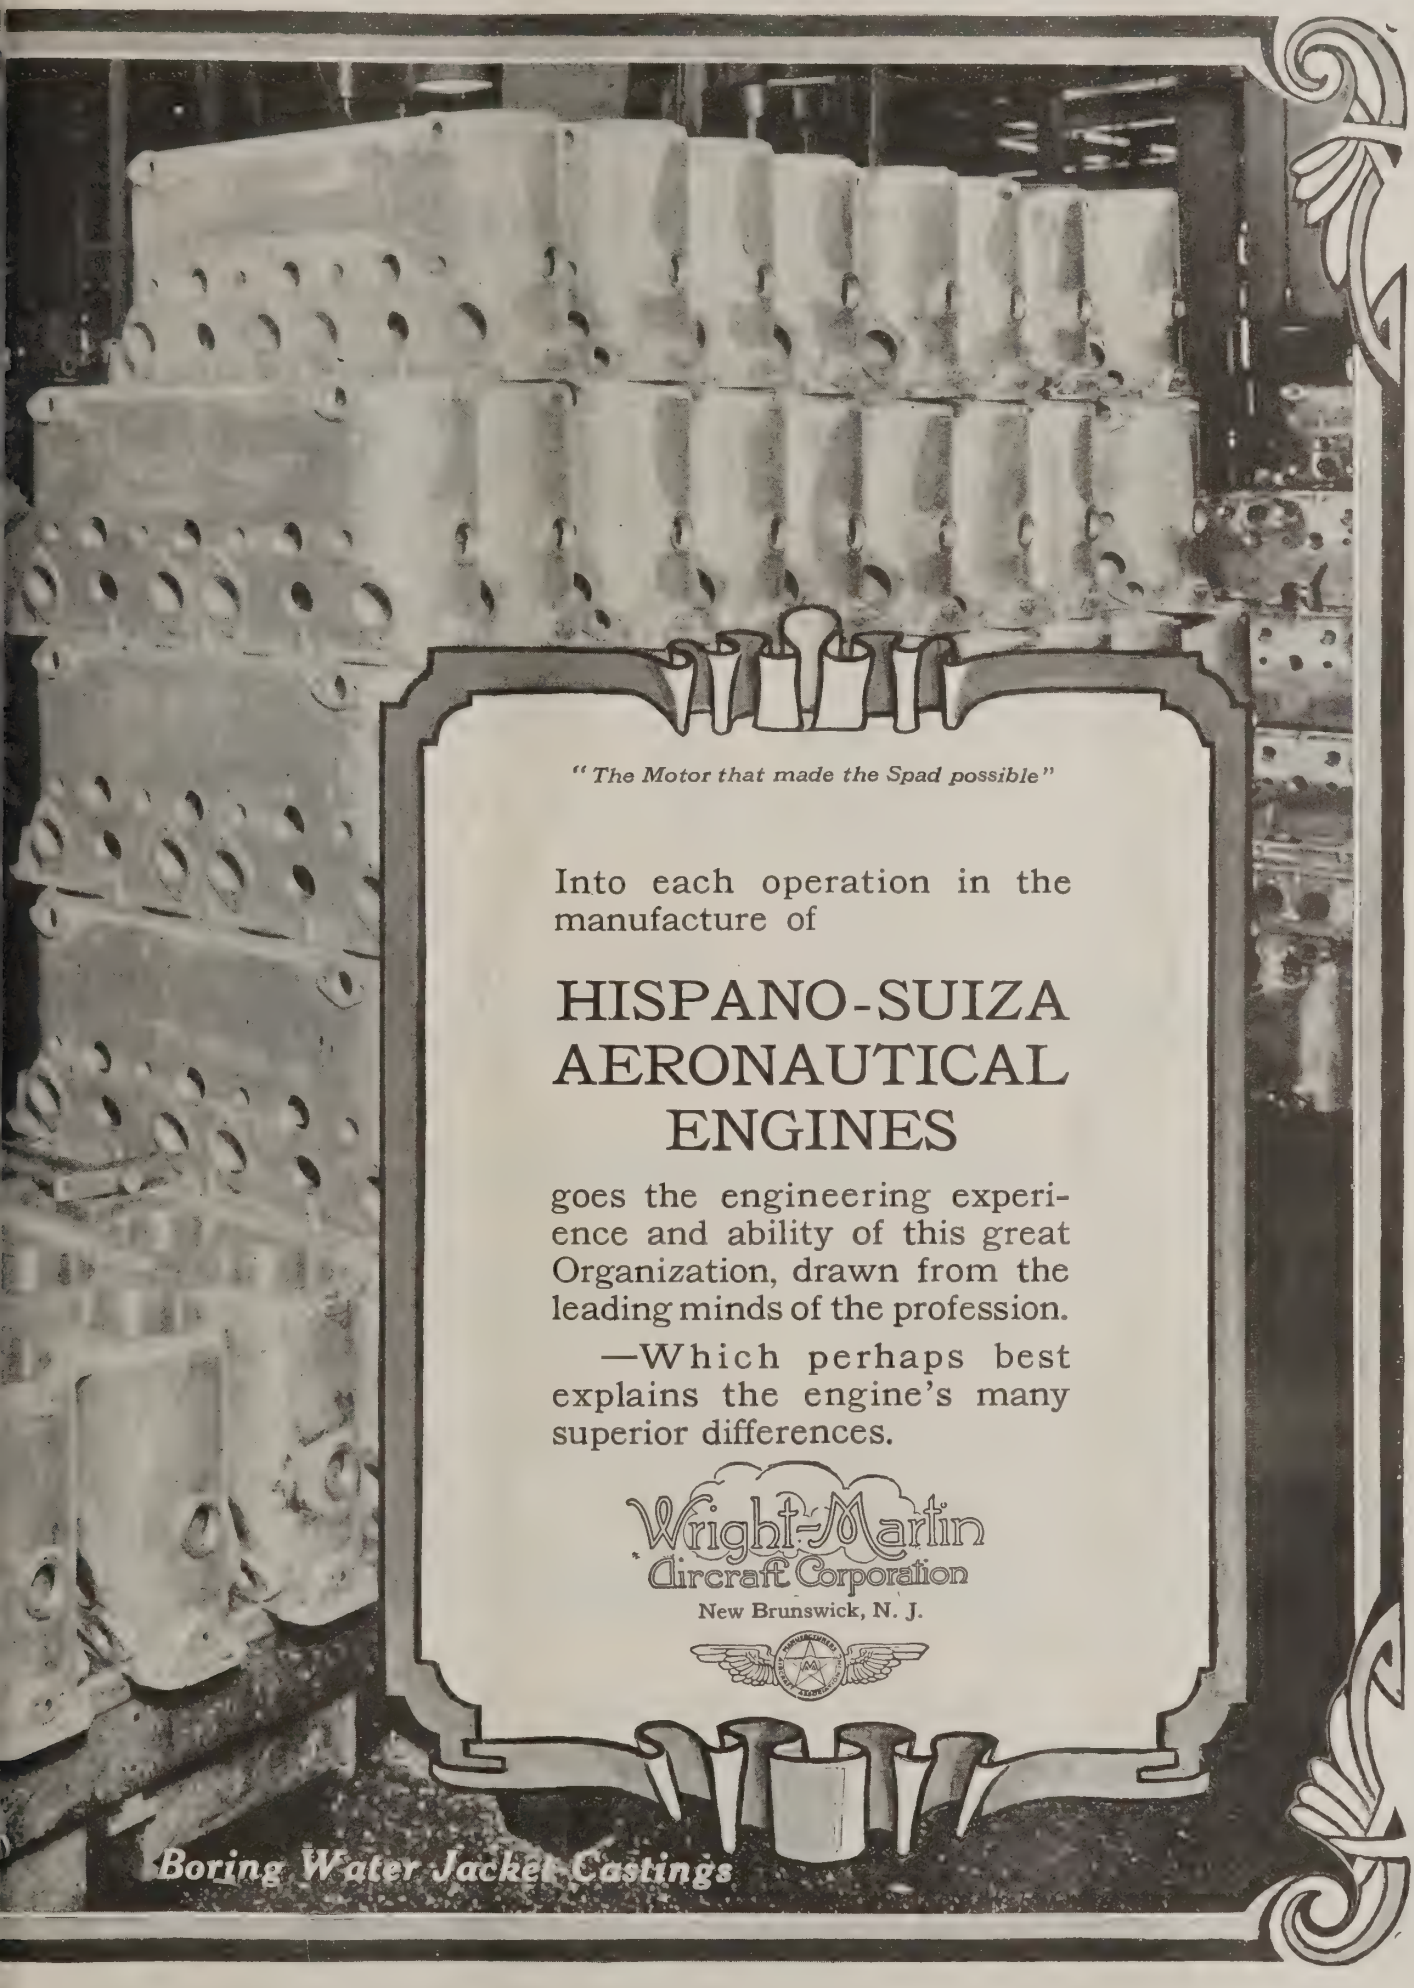
Like the Wings of a Bird!



Christmas Airplanes



The wings of Christmas Airplanes are flexible like those of a bird. They flex vertically, diagonally and along the line of flight. This adjustment is automatic, perfectly taking care of varying wind pressures. These features make for safety, speed and ease of control and are possessed by no other type of plane.

Christmas Airplanes do not suffer from wind shock. Write for full information.

Boring Water Jacket Castings

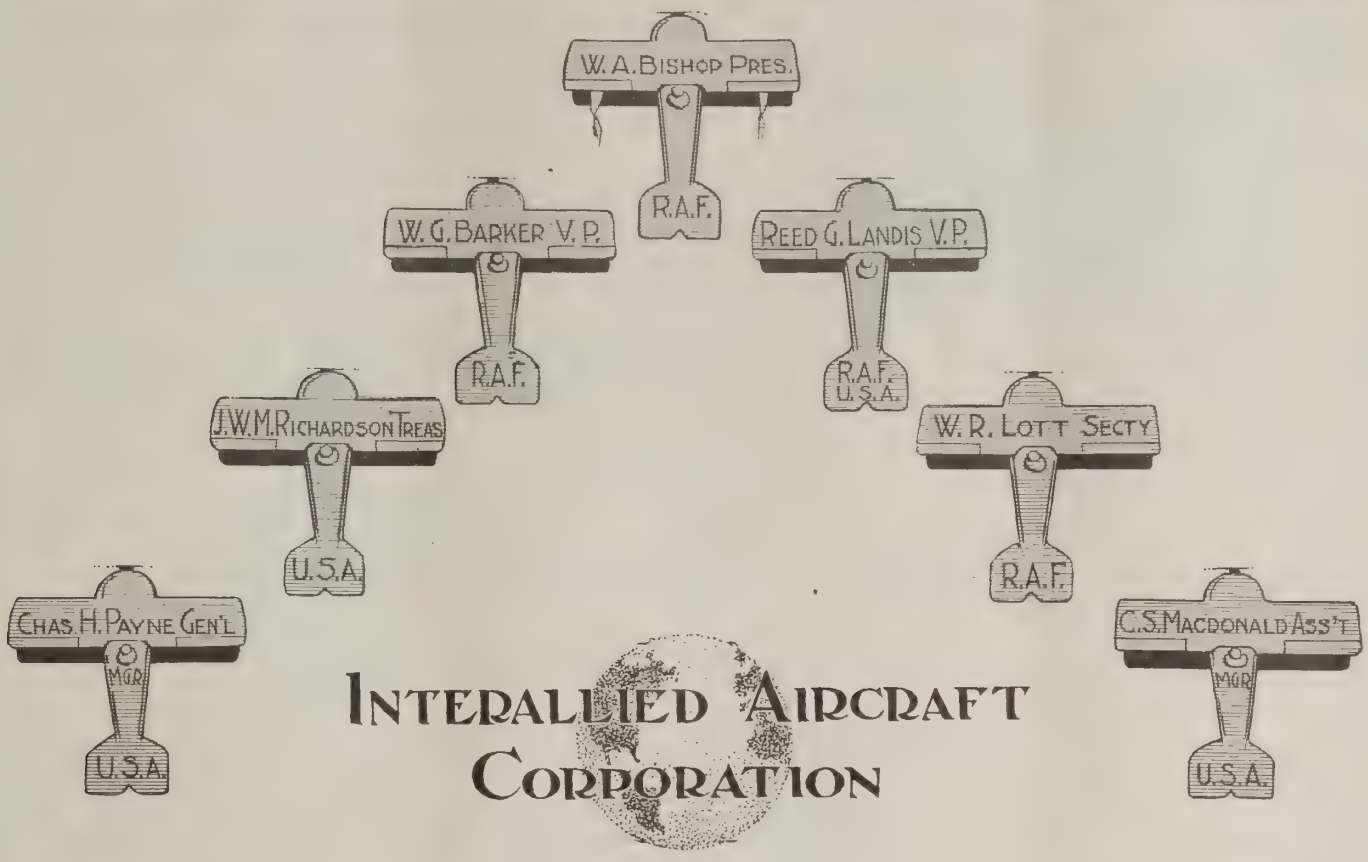
Performance of the B.-G. Model 1 A Spark Plugs used on Liberty motors and two Hispano motors, which flew in the Great Toronto-New York Aerial Derby.

The names of the pilots using the B.-G. plugs, the order in which they finished, the total flying time before and including this race, and the plug performance on each ship are given below:

Place	Time in minutes	Motor	Name of pilot	Total flying hours of plugs	No. plugs missed	No. plugs failed
1	465¼	Liberty	Lt. B. W. Maynard	11	3	1
3	524¼	Liberty	Lt. D. B. Gish	22	0	0
4	545¼	Liberty	Col. G. C. Brandt	10	0	0
5	559¾	Liberty	Lt. M. J. Plumb	60	0	0
6	562	Liberty	Lt. P. H. Logan	10	0	0
7	564	Liberty	Lt. Ben Adams	90	0	0
8	570	Liberty	Lt. John P. Roullet	10	1	1
9	572	Hispano	Maj. R. W. Schroeder	12	1	0
10	576	Liberty	Sgt. C. B. Coombs	14	0	0
12	597½	Liberty	Lt. R. D. Midkiff	70	0	0
13	602¼	Liberty	Lt. Ross Kirkpatrick	12	0	0
14	607¾	Liberty	Lt. W. C. F. Brown	10	0	0
15	621½	Hispano	Lt. Charles Colt	14	0	0

Lieut. Gish used the same ship with the same set of plugs after Lieut. Brown completed the race.

The B.-G. plugs that completed the race received no attention whatsoever during the race and did not lose a cylinder from any cause. All of the B.-G. plugs used in this race and not listed as failures are still flying.



All the B.-G. plugs are listed as "Permissible for use on all service motors in the Army Air Service."

When ordering be careful to specify the B.-G. 1 A for ordinary service or cross country flying and the B.-G. 1 B for long non-stop cross country flying and extremely high temperature work.

Surgery by Aeroplane

IT was once the exceptional surgeon who made his rounds by automobile. What about visiting patients by aeroplane?

Not a bad idea, according to Dr. F. A. Brewster, of Beaver City, Nebraska. Called to Herndon, Kansas, to perform an operation, Dr. Brewster covered fifty-five miles in fifty minutes, reached his patient, operated, and returned in another hour to his home. He had Curtiss service. His is one of a number of experiences showing how the air road is the road to patient when *time-saving* is *necessity*.

A Message About Advertising

FROM THE

U. S. Department of Labor

If you are not advertising, then advertise because it saves money for you and it reduces the price to the consumer.

Advertising prevents profiteering. It insures honest profits and makes them permanent.

The message of the U. S. Department of Labor to merchants and manufacturers and to all progressive American business men is to advertise.

Tell the public about your goods. The consumer has plenty of money. He is willing to spend it and we want him to spend it on American-made products. The easiest, quickest and most economical way in which this can be accomplished is by advertising.

Start your campaign right now.

U. S. DEPARTMENT OF LABOR
W. B. WILSON, Secretary.

ROGER W. BABSON,
Director General, Information and Education Service.

SALE OF NAVY

Flying Boats, Seaplanes, Aeronautical Engines, Spares

There will be offered for sale by sealed proposals to be opened at Bureau of Supplies and Accounts, Navy Department, Washington, D. C., at 2 P. M., 22 September, 1919, a large assortment of SURPLUS, HEAVIER THAN AIR EQUIPMENT. Most of this equipment is new and in excellent condition; many planes have never been uncrated.

The sale will include the following:

83 Flying Boats, HS-2-L, with 330 h.p. Liberty engine.
52 Flying Boats, H-16, with 2 330 h.p. Liberty engines.
20 Flying Boats, F-5-L, with 2 330 h.p. Liberty engines.
50 Seaplanes, Aeromarine Model 39-B, with Curtiss 100 h.p. engine.
10 Flying Boats, Aero Model 40, with engines.
2 Curtiss (GS-4) Gnome Speed Scouts.
1 Boeing Seaplane with engine.
1 Seaplane, Aeromarine, Type 39A, without engine.
250 Curtiss OXX-6 engines, 100 h.p. each, new.
50 Curtiss OXX-6 engines, 100 h.p. each, used.
13 Curtiss OX-2 engines, 90 h.p. each, used.
3 Curtiss OX-5 engines, 90 h.p. each, used.
13 Curtiss OXX-3 engines, 100 h.p. each, used.
51 Hispano Suiza engines, 220 h.p. each, foreign built.
20 Hall Scott engines, used.
32 Gnome engines, 100 h.p. each, new and used.
9 Salmson Hydro-Glycier engines, 220 h.p. each, used.
Sets of spare parts.
Handling trucks.

The above materials are stored at the Fleet Supply Base, South Brooklyn, N. Y., Naval Aircraft Factory, Philadelphia, Pa., Naval Aircraft Storehouse, Gloucester, N. J., and Naval Air Station, Hamptom Roads, Va.

Inspection is invited and may be arranged for with the Supply Officers of the above Naval Stations. Schedules of sale giving full description and complete data together with form for proposal is obtainable from above officers or at Salvage Section, Bureau of Supplies and Accounts, Navy Department, Washington, D. C.—JOSEPHUS DANIELS, Secretary of the Navy. 8-29-19.

A United States Naval Officer Says:

"The engines on the C-5 are the most economical built. They have recently undergone some wonderful tests in Washington, and it was found that this type motor is almost impossible to wear out."

—*New York Times*

The C-5 holds the world's record for non-rigid airships for a non-stop long distance flight.

Big Increase in Insulator Efficiency

Half Again as Much Resistance to Current When Heated

In the high-speed, high-compression motors of today spark plugs must work in heat undreamed of a short time ago.

Yet under intense heat the insulator that once worked perfectly, actually becomes a conductor of the electric current — fails to supply the explosive spark.

But science has now more than kept pace.

Experiment 3450 in the tenth year of unremitting original research work in our insulator laboratories has produced an insulator with half again as much resistance to current when heated.

Champion Dependability takes so long a step forward that it seems well nigh inconceivable that any future motor will ever again develop heat enough to threaten short-circuiting through the insulator.

This greater dependability is yours if you merely take the pains to see that "Champion" *is on the insulator* of your spark plugs as well as the world trade mark on the box.

Champion Spark Plug Company, Toledo, Ohio

Champion Spark Plug Company of Canada, Limited, Windsor, Ontario
